The code sets forth employers' and employees' responsibility in carrying out its provisions. Every employer "or person exercising direction or control over any person or persons who remove any safeguard or safety appliance or device, or over any person or persons for whose protection it is designed shall have such safeguard, safety appliance or device so removed promptly and properly replaced," it is stated.

Employees are required under the code to "use all safeguards, safety appliances or devices furnished for their protection." Each employee is responsible for carrying out safety standards which may concern or affect his conduct.

Building Up Worn Metal Parts by Electrodeposition

A Discussion of the Relative Merits of Copper, Nickel and Iron for Building Up Worn Bearings and Other Metal Parts by Electrodeposition—Factors Which Should Be Considered in Choosing the Proper Metal for a Particular Application

By W. E. HUGHES, B.A. (Camb.)

THE impetus given by war necessities to the practical application of the electrodeposition of metals has manifested itself in several directions. Prominent among the uses made of the art is the restoration to gage of worn parts of airplanes and other mechanisms. This process has come to be known as "building up"; and it was adopted and practiced, more or less successfully, in a number of government workshops in France, England and America during the war. The metal deposited upon the worn and under-gage parts was usually iron, though copper was employed in some cases, especially where the deposit had to serve the purpose rather of a bushing than a bearing surface. Since the armistice (and infrequently before it) nickel has been used to the same end.

The object of the present paper is to examine critically the advantages and disadvantages of the use of the three named metals, the idea being impartially to assist in his choice of metal any engineer who may contemplate using the "building-up" process. This appears to be the more necessary as there seems to be an idea prevalent that there is something new in the use of electrodeposition for "building-up" work. There is, indeed, nothing new in this use at all. The extention of the methods of electrodeposition to the end under consideration is not, in itself, new; what has happened, in fact, is that it has now been recognized that such methods can be employed more generally and for a greater number of similar ends. No claim to a patent covering the idea involved could be for a moment substantiated in a court of law; the element of novelty would be wanting.

General Remarks

It is necessary at the outset to make a few general remarks in regard to the electrodeposition of metals as practiced by those seized by sudden enthusiasm for it to this or that end. Almost all such persons seem to think that they have discovered something; and they do not therefore hesitate to style themselves inventors.

Such displays were common in 1914. The excellent work already done long before by C. F. Burgess and C. Hambuechen,[1] A. Pfaff,[2] F. Foerster and his pupils[3]—to mention only a few serious investigators—was unknown in general. Alexander Watt[4] and M. von Jacobi[5] were spectral beings of the past! The same illusions may quite well exist in regard to building up with nickel. The text-books still contain recipes for making nickel solutions that are based upon the out-of-date double sulphate of nickel and ammonia. Such solutions are quite useless for the formation of thick electrodeposits of nickel. The reasons why this is so have been pointed out elsewhere; it is sufficient to state here that only such solutions as are based upon the "single salts"—nickel sulphate—are of any real use for building-up work.

Solutions Recommended

Before discussing the main theme of this article—namely, the relative merits of copper, iron and nickel for "building-up" work—it will perhaps be useful to indicate briefly one solution which can with advantage be employed for depositing each of the metals mentioned, respectively.

For depositing copper, there is no more useful solution than that composed of copper sulphate (2½ to 3 lb. of pure crystals per gal. of solution) and sulphuric acid (4 to 6 fluid ounces of pure 1.84 acid per gal.). This is known as the acid copper bath. The current density which should be employed varies according to whether the solution or work is to be moved or agitated during the process of deposition, or not. If not, then the current density should be 10 to 12 amp. per sq.ft. of surface to be deposited upon; if movement is employed, more current—a higher current density—can be used.

For depositing iron, one of the best solutions to use is that composed of ferrous chloride and calcium chloride. The following proportions of ingredients have been found to give excellent deposits up to an inch in thickness: 9 lb. of ferrous chloride, 10 lb. of (anhydrous) calcium chloride and 1½ gal. of water.[6] These will make approximately 3 gal. of solution. The solution should be heated to above 80 deg. C. The current density employable is from 80 amp. per sq.ft. upward, yielding a thickness of deposited iron of from 0.004 in. upward per hour.

For depositing nickel, a bath composed of nickel sulphate (about 3 lb.), magnesium sulphate (6 to 8 oz.), powdered boric acid (1 to 4 oz.) and 1 gal. of water is of very general service for "building-up" work. The solution is worked at the ordinary temperature and at a current density of 10 to 15 amp. per sq.ft.

In general, it may be said that the operations required to prepare the surface to receive the deposit are as important as the deposition process itself. That surface must be clean and free from all scale, dirt and grease. Unless it is, failure will almost certainly result, for the deposits will not adhere to the articles on which they are formed. Failure will cause waste of time and money, and it is essential in such a process as that called "building up" that the matter of cost should always be in the forefront of the worker's mind. It may be mentioned here that reliance on any cleaning property that the plating solution may possess is mis-

placed; no one who indulges such reliance should ever be in charge of a plating plant.

Choosing the Proper Metal

Each of the three metals copper, iron and nickel has its uses in "building-up" work. But before any one of them is employed for that purpose, careful stock should be taken to insure that the metal adopted in any particular case is the best of the three to use for the purpose it has to serve. The decision in each case will be affected by considerations of efficiency and economy. The former involves a survey of the physical (including mechanical) properties of the three deposited metals; the latter will be very largely affected by the costs of materials and process. On the one hand, it is useless to employ a comparatively soft and tough metal like copper in cases where a hard metal is required; and, on the other hand, if a cheap metal, such as iron, will serve the purpose one has in view, it is obviously a needless increase of cost to use nickel or copper, other things being equal. Again, both the ease and general costs of deposition must be considered. It will therefor be of advantage to consider each metal separately (though at the same time comparatively) from the points of view of efficiency and economy.

Applications of Copper

During the late war the writer used copper for "building up" such work as pump-sleeves, ball races, airplane engine cylinders, and the like. In many cases the metal had to serve as well the purpose of a sort of binder, similar to the purpose served by lead in the instances cited by G. B. Hogaboom.[1] In other cases it was necessary that the metal used should be a good conductor of heat or electricity. In such cases as these copper was the only metal that would suit all the purposes required. Hence copper was used; it was the only one available and thus could not but be the most economical and efficient.

Applications of Nickel

If a modern nickel solution is employed, nickel-plating is certainly not uneconomical, where nickel is the proper metal to use. Rapid work can be done and cathode losses are small; those facts, separately or together, mean in effect that floor space is minimized, and overhead and other charges, such as rent, outlay on plant, laid up capital and so on, are reduced. But the question as to whether nickel is the proper metal to use is an important one. As compared with copper, its electrical conductivity is lower; so also is its heat conductivity. Hence it cannot be efficient to use nickel if it is important that the plated article should not suffer as a whole in respect to heat or electrical conductivity. That is one instance. Another is where grip or binding is advantageous. If, as sometimes happens, it is necessary to "build up" the threaded end of some piece of mechanism, the use of nickel would result in a less efficient product than if copper were employed, because copper would make a better joint than would nickel, since the former is both tougher and more malleable than the latter. Still another case is where some amount of machining or cutting is required to be done on the plated article. The consequence to machining tools of using nickel for copper was brought home to the writer a few years ago. Complaints reached him that the cutting edges of tools in the machine shop were being seriously injured through their use on deposited nickel, and the employment of that metal had to be abandoned.

Applications of Iron

It may be stated quite generally that, unless some special reason exists for using copper or nickel, iron should always be used for "building-up" work. It has been said lately that there is no reason to use iron, because nickel is cheaper. As a general statement this is grossly inaccurate in as far as "building-up" work is concerned. In the first place, pound for pound, nickel anodes (cast or rolled) are much more costly than Swedish (or any other) iron. Then, on the cathode side of the bath, there is no nickel solution known that will give, in everyday workshop practice, good, close-grained deposits of metal at a current density of 100 to 150 amp. per sq.ft. Such can be obtained with the greatest ease from the ferrous calcium chloride solution.

The writer has obtained excellent deposits 0.02 in. in thickness, at a working current density of 200 amp. per sq.ft. and under still-vat conditions. Moreover, working at that current density, deposits can be formed at the rate of 0.009 to 0.010 in. per hour. The refined method of the Oettel's coulometer is not necessary to prove this; the screw-gage is sufficient. The theoretical thickness of deposited iron per hour from a bath worked at 20 amp. per sq.ft. is (very approximately) 0.001 in. Hence there is but very little less of cathode efficiency when working with the double chloride bath at the current density mentioned (200 amp. per sq.ft.) and under ordinary workshop conditions. Thirdly, gallon for gallon, the cost of a modern nickel solution—and no other than a modern one is of any use—is greater than the cost of a good iron-depositing solution. Fourthly, the working costs other than those of upkeep of the bath—costs such as labor, rent and other dues, and so on—will certainly not be greater in the case of iron than in that of nickel. Under proper management they should be much less, since, other things being equal, the greater the output of a bath the less the cost of the product; and it cannot be gainsaid from workshop experience that the output of an iron-depositing solution, such as the ferrous calcium chloride bath, is several times greater than that of any nickel bath yet invented, even though the latter be worked hot.

To take a specific instance—it is required to plate a crankshaft, say, with 0.006 in. of metal. This can be done with ease in the iron bath mentioned in from 1 to 1¼ hours, working at a current density of only 140 amp. per sq.ft.; the writer has done it many times. In a nickel bath the time required would be at least 3 hours, even allowing that nickel bath could be worked, commercially, at 40 amp. per sq.ft. Hence the iron bath can give more than double the output from the nickel bath; or, alternatively, for a given output the vat room required for iron deposition is less than half that required for nickel deposition. And on the score of relative cost there are many other arguments in favor of iron. But apart from actual net working cost, there is efficiency to be considered. This depends in great part on the nature and properties of the product; an inferior product is too costly at any price. As regards the product in iron deposition, it may truly be said that much more is known about it than about deposited nickel. The structure that iron will have is known, no matter what the type of bath used (sulphate or chloride) or the conditions under which it is formed. Little

[1] *Trans. Am. Electrochem. Soc.*, 1919, vol. 35, p. 399.

indeed is known of the structure of nickel deposits. Since in the case of deposited metal, structure governs or determines properties, it follows that one can obtain from iron-depositing solutions whatever kind of metal one needs within the limits of the properties of electro-deposited iron. Control therefore is well-nigh complete. Again, when one has obtained a nickel deposit, it is not easy to do anything with it. It is difficult to machine, and it cannot be heat-treated to produce a case-hardened effect or to be made one with the base metal. Both these things have been proved possible with deposited iron on iron or steel.

Nevertheless it would not be true to say that there are not occasions when it is preferable to use nickel rather than iron. The point here is that iron should be used wherever possible, unless there is some overriding reason for the employment of nickel or some other metal. And further, to say generally that nickel deposition is cheaper than that of iron is to state that which is contrary to fact.

The importance of the structure of the deposited metal has been already mentioned. This is indeed a matter for serious consideration when the question as to which metal shall be used for "building-up" work has to be decided.

Thermal Stresses in Car Wheels

MORE than 2 years ago a research was started at the Bureau of Standards to investigate the stresses in the plates of chilled iron car wheels caused by heating the rim, a condition approximating that of service where on long grades, it is said by some railroad men, the tread reaches a dull red temperature.[1] Later, a similar investigation on steel car wheels was started.

In the special thermal stress tests for both investigations, the wheel was mounted on a hollow water-cooled 6-in. axle. The axle in turn rested upon cast-iron and concrete support, such that the bottom of the wheel was 2 ft. 8 in. above the floor. A soft steel resistor 3½ in. in width and ¼ in. in thickness was placed on the tread of the wheel but insulated from it by a thin sheet of perforated asbestos, and an alternating current of 1,000 to 1,500 amp. at 15 to 30 v. from a 30-kva. transformer was passed through the resistor. As the wheel was in an upright position and remained stationary throughout the test, it was readily possible to bring the resistor itself to a red heat within 5 to 10 minutes. Undue radiation of heat into the air was prevented by the use of asbestos covering. The tread of the wheel attained a maximum temperature of approximately 380 deg. C. (716 deg. F.) in each experimental run.

In order to interpret the results of these tests it was necessary to determine satisfactorily the distribution of temperature in the wheel from tread to hub. Copper-constantan thermocouples of No. 30 B. & S. gage wire were used; seven couples were used along a vertical radius at approximately 2 in. intervals, and seven others similarly located along the horizontal radius. Readings were taken along both radii for the purpose of obtaining duplicate results. Two other thermocouples were inserted into the treads of the wheel; thus four couples, one in the resistor, were placed at equidistant points in the tread of the wheel and assurance was given that uniformity of tread temperature was attained.

A 2-in. Berry strain gage was used for measuring the deformation, readings being taken at 1-in. intervals on both the vertical and horizontal radii. It will be observed that these readings were taken over a considerable area, this being the only manner of satisfactorily determining the point of maximum stress.

Identical rates of power input were maintained for each test in order to obtain comparative results. It was necessary to increase the power input near the end of the test to attain the desired tread temperature in a comparatively short time.

The strain gage readings represent the deformations due to thermal expansion of material and strain due to tension caused by expansion of the rim of the wheel. Having determined the coefficient of expansion and tensile properties of material in auxiliary tests, the value of the strain was obtained by deducting expansion due to temperature from the total deformation and the strain in turn was translated into stress in pounds per square inch on the stress-strain curves.

In the investigation of chilled iron wheels, twenty-eight wheels of several weights and designs were tested at the bureau and of this number 57 per cent developed circumferential cracks near the hub, of various magnitudes. All but two of these wheels were double-plate M. C. B. and Arch plate type and all the failures occurred in the face plate of these types, while of the two single-plate wheels tested no failures occurred.

Results obtained in the tests of sixteen steel wheels may be summarized as follows:

(1) None of the steel wheels failed.

(2) Because of the movement of the hub with respect to the rim, on account of the heating of the rim, a beam effect is produced in the plate which induces tensional stresses near the hub and stresses in compression near the rim on the face of the plate, while on the back of the plate the stresses are approximately equal in magnitude but reverse in nature.

(3) These effects were observed in new wheels, while the stresses on the face of the plate of old wheels were in tension near the hub and at the rim they decrease to practically nothing, this difference from the new wheel probably being due to the quantity of metal worn away.

(4) The magnitude of the maximum stresses developed approximated the yield point of the material as determined in tensile tests.

(5) After the first series of observations had been completed on the new wheels, an apparent set was obtained which was not the case in succeeding series of observations nor in tests on old wheels. The maximum stresses were in the surface of the plates and were beyond the yield point of the material.

[1]This paper has been completed and will appear shortly as a Technologic paper.

New Public Service Power Map Issued

A map of New Jersey showing the location of the power stations and transmission lines used in public service and the names of the public utility companies has just been published by the United States Geological Survey. This map will be of interest to municipalities, manufacturing companies and other organizations contemplating the use of electricity for power or light. Similar maps are now available for New York, Pennsylvania, Massachusetts, Rhode Island, Connecticut, Maryland, Delaware, District of Columbia, Vermont and New Hampshire. Maps may be purchased of the Director for 50 cents each.

Synthetic Cast Iron, Made in California

By Larry J. Barton
Metallurgist, Southern Pacific Railway Co.

A STEEL mill was put into operation in April, 1920, at the general shops of the Southern Pacific Co., Sacramento, Cal., for the production of steel castings, forging and rolling ingots. Necessary ingot molds were made at our own iron foundry from ordinary pig iron, but it was immediately found that these molds were not suitable. They cracked badly in use; some would crack the full length of the mold, while others would crack completely around the top. Failures were very heavy, some molds going only one heat before having to be scrapped. Upon chemical examination the trouble was thought to be in the phosphorus content, the percentage found ranging from 0.40 to 0.70 per cent. (See Table I of chemical analyses.)

A purchase of the ordinary grade of bessemer iron, with phosphorus below 0.20 per cent, was then made. Molds cast from such iron proved to be satisfactory in every detail, the average number of heats from each mold being about 70. (See Table I.) As this pig iron

was purchased for trial, it soon was used up and we were again faced with prospective mold trouble. There was no available bessemer pig for ready delivery on the coast at the time, and as a last resort we turned to the electric furnace.

Believing that iron made from steel scrap would be as good as the general bessemer pig, we determined to manufacture some. Having noted some time before that a French concern used high manganese in its ingot molds, we decided to try its analysis. As this iron was to be experimental, we did not care to move all the molders' rigging from the iron foundry to the steel mill, so it was decided to pour the iron into pigs, and then remelt it in a cupola and pour the molds at the iron foundry, where all the accessories for doing this kind of work were located. With this in mind, it was decided to get the carbon in our pig iron somewhat lower than finally wanted, believing that the pick-up in the cupola would counterbalance any small amount left out in the electric furnace. Furthermore, it has been found that in making synthetic iron it is a very easy matter to get the carbon up to about 3.00 per cent, but from there on many difficulties are encountered. Table I shows the analyses desired—somewhat lower in Mn and higher in Si than the French mold we were imitating.

The furnace is a standard 6-ton Heroult, basic lined. Electrical equipment was made by the General Electric Co.

As shown in Table II, we were going to use steel scrap, and were not forced to slag off to reduce phosphorus; therefore we turned our attention to reducing sulphur. First, old electrodes were broken into pieces about 4 in. in diameter and thrown on the hearth. This was to give the required carbon to convert the steel into cast iron and formed a necessary reducing atmosphere during the melting-down period. While this worked well, it was found better to use ground coke instead of the lumps of carbon. Lumps tend to rise and interfere

TABLE II—CHARGE BURDEN

Item	Wt.	C	Wt.	Mn	Wt.	Si	Wt.	P	S

Melting loss	475 lb. or 3.96 per cent.								

with the slag after the metal has been melted. We charged the coke first, then a coating of lime (180 lb.), enough to make one-half of our slag, or 1½ per cent of the charge. Old spring steel was charged next, then the borings, and the forge flashings on top to give a good contact. As the charge melted down and the electrodes dug holes, they were filled with the remainder of the forge flashings.

Furnace Log

9:55 a. m. Current on.

12:00 m. Melted down, and all scrap knocked off side walls. During above period the rest of the slag, or another 1½ per cent of the charge, added around the electrodes. This slag is now foaming slightly and powders white on exposure to the air.

12:05 p. m. First metal test taken. Poured flat into sand mold. When black, quenched in water and broken. Fracture shows clear, white iron. This sample could be drilled only a small amount. Analysis: Carbon 2.48 per cent, manganese 0.27 per cent. Quite a few pieces of the old electrodes floating on bath were raked off, and an equivalent amount of finely ground coke added.

12:30 p. m. 100 lb. more lime added to bath, together with 32 lb. of ground fluorspar. Slag tests powdering white and giving off a very strong odor of acetylene.

2:00 p. m. Second metal test taken. Showed clear white and was too hard to drill. 140 lb. ferromanganese added.

2:15 p. m. 300 lb. ferrosilicon added. Test taken showed a very close-grained gray iron, which was still too hard to drill.

2:30 p. m. 70 lb. ferromanganese and 165 lb. ferrosilicon added. Test showed a very fine gray iron, rather close grained. Drilled easily, but was apparently very tough from the high manganese. Analysis: Carbon 2.85 per cent. Added about 50 lb. of finely ground coke and kept rabbling this into metal for ½ hour.

3:00 p. m. Trapped. Final test gave an excellent appearing gray iron, hot and running well in the pig bed.

These pigs were then taken to the iron foundry, remelted in a cupola and made into ingot molds. While the phosphorus and sulphur increased 0.12 and 0.07 respectively in the cupola (see Table I), these molds stood up better than any we had ever had. The original high-phosphorus molds averaged 30 heats, molds from purchased bessemer iron averaged 70 heats, while molds from synthetic iron made as above described averaged 110 to 130 heats. These molds no doubt would have stood up even better had they been cast directly from the electric furnace, thus eliminating the pick-up of phosphorus and sulphur from the cupola.

The economic possibilities of this process here on the Pacific Coast are great. In districts where blast furnaces are common there is not much need to worry

about the supply of available pig iron, but here it is a different matter, especially when freight rates and time of delivery are considered. During 1920 the average cost of pig iron laid down in Sacramento was $45 per net ton. Of this cost $22.40 was for freight alone. Add to this the cost of coke and the other incidental expenses for remelting in the cupola, and then compare this sum to the cost of molten electric furnace iron, which we figure is less than $25 per ton.

If cast-iron borings could be obtained, the expenses of melting would be even less, due to a saving on ferro-alloys, together with lower melting costs. The most logical method would be to annex a molding floor to the steel plant and pourcast directly from the electric furnace. A heat of cast iron could be poured and then a heat of steel, making the one furnace do the work of several, as at present. In addition, the castings would possess high quality; the metallurgist is enabled to meet any specification with ease; and the plant can handle scrap impossible to melt in any other way, since the possibilities for refining are not to be excelled.

A New Dye Standardizing Machine

THE importance of satisfactory mixing and standardizing equipment in the dye industry is not likely to be overestimated. That the manufacturers produce dyes which can be safely guaranteed as to strength and color is one of the fundamental requirements of the consumer. The selection of the machine to be used for this purpose, therefore, demands the very careful consideration of the manufacturer. One type of mixer, which has recently been developed by the Stevens-Aylsworth Co. of New York, has a number of interesting features. It combines the principle of the mechanical agitator with the tumbling action of a revolving drum. The latter feature prevents the accumulation of any quantity of unmixed material in the space that must necessarily exist for the clearance of the revolving agitator in the stationary type of mixer. The accompanying figures will perhaps be of value in explaining the principles and operation of this machine.

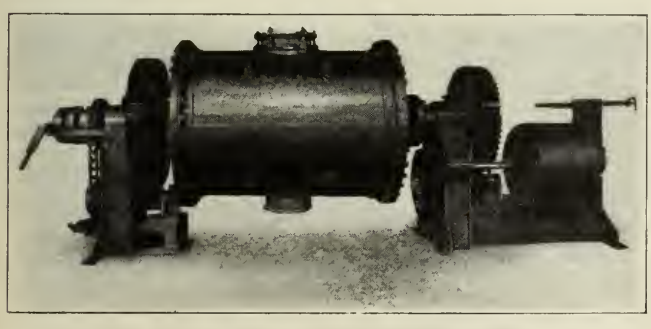

FIG. 1—MIXING MACHINE SET UP FOR TEST RUN

The agitators are in the form of two opposed helical spirals which toss the materials about inside of the drum, moving them from the ends of the machine toward the center. As they throw the material past the center in each case, the materials in the center are forced to the ends, thus thoroughly blending all parts of the mixture.

The vanes are made of flat plates which cut through the material and roll it over on itself on its way to the center and they also in each revolution force some of the materials from the bottom up to the top.

In addition to the revolutions of the vanes the drum itself revolves, but in the opposite direction from the vanes—that is to say, if the vanes revolve clockwise, the drum revolves counter-clockwise.

In the operation of this machine, as well as in all other machines in which there are agitators, there is a tendency for the material to adhere to the ends and sides of the drum, but as the latter revolves these materials will fall back into the mix when the drum has brought them up to the top. Furthermore, the slight vibration of the machine will assist in shaking off the materials adhering to the sides.

The loading and unloading of the mixer are practically dustless operations and it has been found possible to

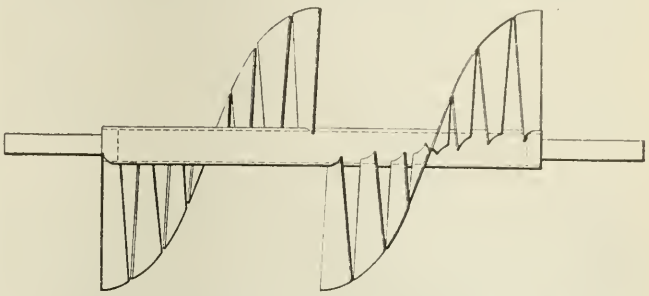

FIG. 2—INTERIOR AGITATING MECHANISM OF MIXER

unload into barrels for shipment a charge of over a ton in less than 13 minutes.

The small openings shown on the sides of the machines are for taking out samples of the mix. These small openings can be placed in various positions around the periphery of the drum and if desired also on the ends. At a specified time samples are taken from various parts of the mix and submitted to the dye application laboratory for test to determine whether they are up to standard. If so, the mixer is then unloaded.

During the loading of this machine the stirrers or vanes may be kept in motion while the drum is held stationary until all of the materials are charged. After the mix has been brought to the proper standard the drum is stopped and by continuing the revolution of the paddles the machine completely empties itself. Since these spiral vanes overlap each other, any portion of the mix which might lag behind one vane is immediately picked up by the succeeding vane and moved toward the center, thus emptying the machine completely.

The various openings into the machine for loading, unloading and for taking out samples are carefully fitted and are flush with the interior, thus eliminating pockets into which the material could otherwise lodge and escape the action of the paddles.

Recovery of Potash From Wool Washing

A small wool washer for recovering potash from fleeces in a solution of sufficient concentration to make the recovery of the potash profitable has been designed and is being tried out by the Bureau of Chemistry. It is said that the average fleece contains about 4 per cent of potash by weight, but in the ordinary method of washing wool it comes out in such dilute solution that it does not pay to recover the salt.

About 600,000,000 lb. of wool is scoured in the United States each year, and if only 3 per cent of potash is recovered it would amount to 18,000,000 lb. of actual potash that would be available for use in fertilizers.

Secretary Weeks Analyzes Ford's Offer for Muscle Shoals

Secretary of War Transmits Recent Offer for Nitrate Plants and Water-Power to Congress with Business Analysis of Ford's Proposal and His Recommendations—Modified Proposal of Jan. 13, 1922, More Advantageous to the Government Than the First Offer—Original Text

SOON after I assumed the duties of Secretary of War suggestions were made to me by those interested in the development of the power plant and navigation at Muscle Shoals that I should recommend to Congress that an appropriation be made to complete Dam No. 2 (Wilson dam). In response to such suggestions I stated that when a proposal was made which would assure the government a reasonable return on at least the additional money required to complete the project, and an effective use of the development for commercial purposes, I would send it to Congress, as the power to dispose of these plants is vested in that branch of the government.

Ford's First Proposal

On July 8, 1921, in consequence of this statement and of some negotiations with the Chief of Engineers, United States Army, Henry Ford presented a proposal in writing, in which he offered a fixed annual rental of $1,200,000 for Dam No. 2 and its power plant and appurtenances, such rental to commence 6 years after the installation of equipment capable of producing 100,000 hp., and a rental of $200,000 to be paid annually during the first 6 years of the lease. On proposed Dam No. 3 he offered a fixed annual rental of $480,000 commencing 3 years after 80,000 hp. should be developed, and $160,000 per annum for the first 3 years of the lease period. Provision was made for certain upkeep charges and payments to be made toward a sinking fund estimated to be sufficient to amortize approximately $48,000,000 of the cost of the dams. Under this proposal the United States was to undertake the completion of Dam No. 2 and the construction of Dam No. 3. This offer was conditioned upon the United States selling to Mr. Ford Nitrate Plants Nos. 1 and 2, the Waco Quarry and its equipment and the Gorgas-Warrior steam plant and transmission line and appurtenances, all for the price of $5,000,000.

The cost of completing the two dams is estimated by the Chief of Engineers to be, at this time, in round figures, $50,000,000. Consequently, I did not believe that the proposed rental was an adequate return on the government's proposed investment, and suggested that Mr. Ford modify his offer so that it would be based upon an annual payment equivalent to a rate of interest on the total cost to the government completing the projects. On Jan. 13, 1922, Mr. Ford presented to me a proposed modification of his previous offer, by which he agreed to undertake the construction and completion, at actual cost and without profit, of the work referred to in his offer of July 8, 1921, and when completed and ready for operation he offered to pay the United States as annual rental of the property an amount equal to 4 per cent of the total cost of such construction.

At my suggestion Mr. Ford placed in one instrument his offer as modified, which was signed by him on Jan. 25, 1922, and delivered to me on Jan. 27, and which I have the honor to transmit herewith for such action as Congress may deem appropriate.

Modified Proposal

In brief, Mr. Ford offers to undertake the completion of Dam No. 2 and the construction of Dam No. 3 according to the government's plans, for which he shall be reimbursed the actual cost, and to lease the dams and power plants at an annual rental equivalent to 4 per cent of the cost to the government of completing Dam No. 2 and constructing Dam No. 3 (exclusive of the cost of acquiring lands and flowage rights necessary for Dam No. 3). The rentals of 4 per cent are to commence, respectively, in 6 years after Dam No. 2 has been completed to the point where equipment for 100,000 hp. is installed and ready for service, and 3 years after the equipment to develop 80,000 hp. is installed and ready for service at Dam No. 3. In the meantime, during the 6-year and 3-year periods, respectively, he offers to pay upon Dam No. 2 an annual rental of $200,000 and on Dam No. 3 $160,000.

His offer places upon the United States the responsibility for repair and maintenance of the two dams other than the power houses, which power houses and electrical equipment he agrees to maintain at his own expense in efficient operating condition. As compensation to the United States for the repair and upkeep of Dam No. 2 and locks he offers to pay the sum of $35,000 annually, and of Dam No. 3 and lock the sum of $20,000 annually. He also agrees to furnish electricity for operating the locks at each of these dams without charge to the government, and in addition he agrees to pay the sum of $23,373 semi-annually, for the purpose of building up a sinking fund to return to the United States at the end of the lease period, a sum of money which he estimates if invested at 4 per cent will be approximately $49,000,000.

As a condition of this offer he asks that the United States sell to him Nitrate Plants Nos. 1 and 2, the Waco Quarry and the Gorgas-Warrior steam plant, with all appurtenances, for the sum of $5,000,000, payable $1,000,000 down and the balance in annual installments of $1,000,000 each, with 5 per cent interest on deferred payments. As a further consideration to the government he agrees to operate Nitrate Plant No. 2 at the approximate present annual capacity of its machinery and equipment in the production of nitrogen and other fertilizer compounds throughout the lease period, and to maintain it in its present state of readiness, or its equivalent, for immediate operation in the manufacture of materials necessary in time of war for the production of explosives. He further agrees that the fertilizer produced at Nitrate Plant No. 2 shall not be sold at a profit in excess of 8 per cent of the actual annual cost of production thereof, and to turn over to the United States Nitrate Plant No. 2 whenever it shall be required for the national defense. He likewise asks for a preference in opportunity to purchase or lease the property at the end of the lease period and for the right, for a period not stated, to be supplied with electric power at reasonable rates in an amount equal to his average consumption during the previous 10 years, in case the plant is operated and his company does not purchase or lease it. He also states that his proposal must be accepted as a whole and not in part.

In order that you may the more readily understand just what Mr. Ford is proposing to buy and to lease I shall state briefly what has occurred in connection with government development at Muscle Shoals and the character of the government-owned property there.

Description of Property Involved

Without going into the preliminary history in connection with the proposals for the development and improvement of the Tennessee River, which might, if necessary, be traced to the year 1827, it is deemed sufficient for present purposes to invite attention to the letter over the signature of the Secretary of War, dated June 28, 1916, and printed as Document H.R. 1262, Sixty-fourth Congress, First Session, transmitting, with a letter from the Chief of Engineers, reports on preliminary examination and survey of Tennessee River between Browns Island and the railroad bridge below the City of Florence, wherein is contained a full discussion of Dam No. 2, now known as the Wilson Dam, and the proposed Dam No. 3, referred to by Mr. Ford but as to which no construction work has yet been undertaken. The commencement of construction work on the Dam No. 2 resulted from the authority contained in Section 124 of the national defense act of June 3, 1916 (39 Stat. 166,

215, under which the President, in a letter dated Feb. 23, 1918, authorized the construction of said dam, as a result of which allotments have been made at various times amounting to $17,159,610.42 for its construction. The total expenditures on Dam No. 2 have been $16,251,038.14; the greater part of the balance unexpended will be required to meet payments on contracts for power machinery for the dam. A large construction camp has been built, a railroad track laid to the site, complete construction plant assembled, and the dam itself approximately 30 per cent completed.[1]

Water Power Property

Dam No. 2, when completed, will have a total length of 4,267 ft., of which 2,890 ft. is a spillway section, 1,221 ft. will be the power house section and 156 ft. abutments and approaches. The height of the dam above present low water is 95 ft., including crest gates 18 ft. in height. The total height from the bottom of the excavation for the foundations to the roadway on top of the dam will be 132 ft. There have been no expenditures on Dam No. 3, which is located 14.7 miles upstream from Dam No. 2. Dam No. 2, when constructed, will render 14.7 miles of Muscle Shoals navigable, while Dam No. 3 will overflow the remaining portion of the rapids and will improve conditions of navigation for a distance of 63 additional miles. The present estimates of the Engineer Department for the completion of both Dam No. 2 and Dam No. 3 is $50,000,000. Engineers for Mr. Ford have presented a lower estimate, but Mr. Ford has not seen fit to guarantee the construction for this lower figure.

Nitrate Plant No. 1

Situated about 6 miles southwest from Dam No. 2, at Sheffield, Culbert County, Ala., adjacent to the city and along the Tennessee River, is United States Nitrate Plant No. 1, constructed by the United States during the war under an agreement with the General Chemical Co., approved by the Secretary of War on June 14, 1917, for use of its process, and at a total cost of $12,887,941.31. The plant was built under the supervision of the Ordnance Department of the Army to produce 22,000 tons of ammonium nitrate per annum, using the direct synthetic ammonia (modified Haber process) of the General Chemical Co. The details of the process were not sufficiently perfected, however, and the plant proved unsuccessful in a test operation. The construction of the plant was started from an appropriation contained in the national defense act of June 3, 1916, and completed from appropriations made for the national security and defense, armament of fortifications and ordnance service. The total acreage of land embraced within the plant site is approximately 19,000 acres. The plant is now in an idle standby condition, with part of the land leased for farm purposes. The cost of maintenance during the fiscal year 1921 was $75,506.42.

Nitrate Plant No. 2

At Muscle Shoals, Culbert County, Ala., 4 miles northeast of Nitrate Plant No. 1 and 2 miles distant from Dam No. 2, is located[2] United States Nitrate Plant No. 2. This plant was constructed under contract with the Air Nitrates Corporation for the production of munitions of war under contract dated and executed June 8, 1918, at a total expense, including Waco Quarry, of $67,555,355.09. The plant was built for an estimated capacity of 110,000 tons of ammonium nitrate per annum, using the cyanamide process of the American Cyanamid Co. The plant was successful in a 2 weeks' test operation with one-fifth of the plant in use, during which time 1,700 tons of ammonium nitrate were produced, as well as 2,200 tons of cyanamide not converted. The cost of building said plant was paid out of the appropriation for armament of fortifications and ordnance service. The plant site, not including Waco Quarry, embraces 2,306 acres acquired at a cost of $237,711. The plant is now in an idle standby condition, except the 80,000 kw. power plant located thereon, which was leased, together with a transmission line, to the Alabama Power Co. under the provisions of the act of July 28, 1892 (27 Stat. 321) by an instrument dated Nov. 17, 1921, but revocable at any time. The cost of maintenance of said plant for the fiscal year 1921, including Waco Quarry, was $201,674.63.

Waco Quarry

Situated about 20 miles south of Plant No. 2 in Franklin County, and 5 miles southeast of Russellville, Ala., is located what is known as Waco Quarry, acquired by the United States in connection with the operation of Nitrate Plant No. 2, embracing an area of 160 acres, acquired at a total cost of $52,962.88. This quarry has a crushing plant sufficient to produce 2,000 tons of crushed and sized limestone per day. The total cost of said quarry, including buildings and plant, was $1,179,076.80, included, however, as an element of the total cost of Nitrate Plant No. 2. The plant is now in an idle standby condition and a portion of the land is leased for farm purposes.

Gorgas Power Plant

Situated about 88 miles southeast of Nitrate Plant No. 2, in Walker County, Ala., is located what is known as the government-owned Warrior steam plant at Gorgas, Ala. This plant was constructed under contract with the Alabama Power Co., dated Dec. 1, 1917, on land owned or acquired by the said company. It was built in the vicinity of a coal mine with a view to using coal direct from the mines. It has a capacity of 30,000 kw. and the electric power produced at said plant is carried over a transmission line extending a distance of about 88 miles to Nitrate Plant No. 2, to furnish power for the operation of said plant. The total cost of the plant was $4,979,782.33. It was built and paid for from appropriations for armament of fortifications. This property is now being operated as a part of the Alabama Power Co.'s system on a rental basis as provided for in the contract for the consideration thereof, and during the calendar year 1921 netted the government approximately $75,000.

Opinion of Judge Advocate General

Some question was raised in my mind as to the binding effect of certain provisions appearing in the contract for the construction of Nitrate Plant No. 2 by the Air Nitrates Corporation and in the contract for the construction of the Gorgas-Warrior steam plant and transmission lines by the Alabama Power Co., which purported to give said companies options to purchase under certain conditions, but I have submitted these questions to the acting Judge Advocate General, who is of the opinion that at the time these contracts were made there was no authority to sell said properties and hence no authority to give an option for the purchase of same. He holds that as the Constitution vests in Congress the sole power to dispose of and make all needful rules and regulations regarding the property of the United States, and Congress not having authorized the Secretary of War to sell the same, the plenary power to dispose of such property still rests solely in Congress. The acting Judge Advocate General has also held that the provision contained in section 124 of the national defense act directing that the plant therein authorized be operated solely by the government and not in conjunction with any other industry or enterprise carried on by private capital is applicable to the plant as a whole and is a restraint upon its sale. This construction, if justified, would prevent the lease or rental of the plant for private operation. The solution of the numerous legal questions involved naturally occasioned more or less delay in the consideration of the proposals.

Air Nitrates Corporation Option to Buy

In this connection I may say that the Air Nitrates Corporation has notified me in writing that it claims the right to exercise the option which it claims to have under the terms of its construction contract to purchase Nitrate Plant No. 2 on as favorable terms as those offered by Mr. Ford for the property, should the United States determine to accept Mr. Ford's offer. The Alabama Power Co. may make a similar claim in regard to the Warrior plant and line.

To briefly summarize Mr. Ford's offer for the above properties the considerations running to the government are:

[1] See CHEM. & MET. ENG., Feb. 1, 1922, p. 230, for picture showing present condition of dam construction.

[2] See CHEM. & MET. ENG., Feb. 1, 1922, p. 231, for picture showing dam and Plant No. 2.

(*a*) Four per cent on part of the capital necessary to complete the construction of the power projects; (no interest is proposed to be paid upon that part of the government's investment which goes to pay for lands and flowage rights for Dam No. 3, which item is estimated by the engineers to exceed $2,000,000 in probable cost.

(*b*) The payment of a sum semi-annually into a sinking fund calculated to produce about $49,000,000 at the end of the lease periods. This payment amounts to $46,746 annually. In other words, Mr. Ford proposes to pay approximately $49,000,000 at the end of the lease period provided the government has been able to invest his payments at 4 per cent per annum.

(*c*) Mr. Ford proposes to pay $35,000 a year for the upkeep of Dam No. 2 and its locks and the sum of $20,000 a year for the upkeep of Dam No. 3 and its lock. These payments are expected to meet the ordinary upkeep expense with which the government is charged. Mr. Ford assumes the responsibility for upkeep and repair of the power houses and equipment so that ultimately such equipment is expected to be turned back to the government in approximately as good condition as when received.

(*d*) The proposal requires Mr. Ford's company to operate Nitrate Plant No. 2 to its approximate present capacity, which is estimated to be a production of 110,000 tons of ammonium nitrate per annum, and to sell such material at a price not to return a net profit in excess "of 8 per cent of the actual annual cost of production."

(*e*) Mr. Ford's company is to maintain Nitrate Plant No. 2 in its present state of readiness for immediate operation for the production of explosives and is to turn it over to the government, together with such of its personnel as may be required for the national defense.

(*f*) The government will be saved the expense of maintaining and operating the present imperfect facilities for navigation at Muscle Shoals amounting to from $35,000 to $85,000 per annum.

Advantages to Government in Last Proposal

There are a number of advantages to the government in the present proposal that were not apparent in the first offer. Mr. Ford's original proposal of July 8, 1921, contained two paragraphs dealing with the matter of amortization of the cost of construction of the two dams. The first of these paragraphs was numbered 2 and reads as follows:

> At the beginning of the seventh year of the lease period, and annually thereafter, the company will pay to the United States a sum not greater than $39,537 to retire, during the remaining period of 94 years, the total cost of the Wilson Dam and its power house, substructures, superstructures, machinery and appliances, including locks, all taken at $40,000,000; the sinking fund investments to bear the highest rate of interest obtainable, but not less than 4 per cent per annum.

The other paragraph was numbered 7 and reads as follows:

> At the beginning of the fourth year of the lease period, and annually thereafter, the company will pay to the United States a sum not greater than $7,010) to retire, during the remaining period of 97 years, the total cost of Dam No. 3 and its power house, substructures, superstructures, machinery and appliances, including lock, all taken at $8,000,000; the sinking fund investments to bear the highest rate of interest obtainable, but not less than 4 per cent per annum.

In the present proposal the subject of amortization is covered in one paragraph, numbered 10, which reads as follows:

> For the purpose of enabling the government to create and provide a sinking fund to retire the cost of Dam No. 3 at the end of 100 years, the company will, at the beginning of the fourth year of the lease period and semi-annually thereafter for the remaining term of the lease, pay to the United States Government the sum of $3,505; and for the purpose of enabling the government to create and provide a sinking fund to retire the cost of Dam No. 2 at the end of 100 years, the company will, at the beginning of the seventh year of the lease period and semi-annually thereafter for the remaining term of the lease, pay to the United States Government the sum of $19,868.

It will be observed that the provision for amortization in the last proposal is very much more favorable to the United States than it was in the offer of July 8, 1921. By the earlier proposal the maximum amount which the government could realize from the payments made by Mr. Ford at the end of the lease periods would be not to exceed $48,000,000 ($40,000,000 in the case of Dam No. 2 and $8,000,000 in the case of Dam No. 3). The annual payments were in no case to exceed the amounts stipulated, which are the same as in the present proposal as in the former proposal, but the former proposal contemplated a reduction in amount of annual payments to correspond to the excess over 4 per cent interest which might be earned by the sinking fund, whereas under the present proposal the annual installment for amortization is to be paid regardless of the rate of interest earned by the fund. Therefore, if the United States should be able to invest the money at a higher rate of interest than 4 per cent the sinking fund at the end of the lease periods would amount to very much more than $48,000,000. This may be best shown by the accompanying table:[3]

AMOUNT RETIRED BY MR. FORD'S SINKING FUND AT VARIOUS RATES OF INTEREST (COMPOUNDED SEMI-ANNUALLY)

Account of	Semi-Annual Payments	Life of Fund (Years)	Amount Retired at Following Interest Rates		
			4 Per Cent	4¼ Per Cent	4½ Per Cent
Dam No. 2	$19,868	94	$40,919,798	$48,783,949	$58,319,359
Dam No. 3	3,505	97	8,152,137	9,786,054	11,780,690
Total			$49,071,935	$58,570,003	$70,100,049
				5 Per Cent	6 Per Cent
Dam No. 2	$19,868	94		$83,718,097	$176,030,810
Dam No. 3	3,505	97		17,150,545	37,103,880
Total				$100,868,642	$213,134,690

Should the dams be constructed at a cost of not to exceed $42,000,000, as estimated by Mr. Ford's engineers, there would be left to apply on the investment of the government heretofore made whatever the amortization payments would produce in excess of the $42,000,000. If the amortization fund should be invested continuously at 4 per cent there would be at least $7,000,000 to be thus applied, but should it be invested at a greater rate of interest the amount would be increased as shown by the table.

Renewal of Leases

The provision for renewal of the lease which was contained in the proposal of July 8, 1921, was numbered 11, and reads as follows:

> At any time prior to the expiration of said lease period of 100 years the company shall have the right to negotiate with the government for a renewal of the leases for the two above dams, their powerhouses, etc. In the event of disagreement as to terms of the renewal, the United States and the company shall each appoint an arbitrator, and these arbitrators shall choose a third. The decision of the arbitration board of three shall be final and binding upon both parties.

The effect of this provision was to bind the United States to a renewal of the lease for 100 years on such terms as should be determined to be just by a board of arbitration. Under the new proposal the renewal clause is contained in paragraph 17, which reads as follows:

> In order that said company may be supplied with electric power and the farmers with fertilizers after the termination of the said 100-year leases, should the United States elect not to operate said power plants but determine to lease or dispose of same, the company shall have the preferred right to negotiate with the United States for such lease or purchase and upon such terms as may then be agreed upon. If the said leases are not renewed or the property covered thereby is not sold to said company, its successors or assigns, any operation or disposal thereof shall not deprive the company, its successors or assigns, of the right to be sup-

[3] Payments are to be made into sinking fund semi-annually at the beginning of each semi-annual interest period. This sinking (or retirement) fund has nothing to do with Mr. Ford's interest payments, but represents a separate fund to be invested at the highest interest rate obtainable for the purpose of returning to the government within the lease period the largest amount possible, with the above semi-annual payments, consistent with safe investment.

plied with electric power at reasonable rates and in amount equal to its needs, but not in excess of the average amount used by it annually during the previous 10 years.

This paragraph does not bind the United States to renewal of the lease and is in no way an attempt to control the policy of Congress beyond the 100-year period of the present lease, except to preserve to Mr. Ford's company "the preferred right to negotiate with the United States for such lease or purchase and upon such terms as may then be agreed upon." It also attempts to preserve for the company a right to be supplied with electric power for a period not stated "at reasonable rates" in the event the power plants are operated or disposed of to someone other than the company.

Obligation for Maintenance Rests on Mr. Ford

In Mr. Ford's offer of July 8, 1921, no provision was made except possibly by inference, as to who should bear the expense of renewals, repairs and maintenance on the power houses, machinery and appliances which will be erected and installed in connection with the dams. Paragraphs 4 and 8 of the present proposal impose the obligation upon Mr. Ford's company of making such renewals and repairs and effecting such maintenance at its own expense. These provisions impose upon Mr. Ford a considerable obligation.

Lessor to Construct

Under the first proposal the United States was to undertake the building of the dams and power plants, but under the present offer Mr. Ford's company is to do the construction work in accordance with plans and specifications prepared or approved by the Chief of Engineers.

The proposal of July 8, 1921, contained no provision for a termination of the leases in case of default. Paragraph 18 of the present proposal applies substantially the same provisions to Mr. Ford's proposed leases as are contained in the present water-power act.

Paragraph 19 of the present proposal, except the first sentence thereof, has no counterpart in the original proposal of July 8, 1921. The new matter reads as follows:

> Upon acceptance, the promises, undertakings and obligations shall be binding upon the United States, and jointly and severally upon the undersigned, his heirs, representatives and assigns, and the company, its successors and assigns; and all the necessary contracts, leases, deeds and other instruments necessary or appropriate to effectuate the purposes of this proposal shall be duly executed and delivered by the respective parties above mentioned.

Assurance of Contract's Execution

Apparently this is an attempt on Mr. Ford's part to express a personal obligation to assure the performance of the contracts which are to be made by the company which he is to organize. It might be contended that this language is susceptible of a construction to the effect that Mr. Ford is personally bound only to see that his company enters into the contracts required to carry out the terms of the proposal, and this point should be cleared up so that there can be no question as to its proper construction. There should be some assurance that the contracts made by the proposed company will be carried out or some penalty imposed for failure to perform.

Must Maintain Plant No. 2

In the event Mr. Ford's proposal is accepted, the government must make new appropriations amounting to $40,000,000 to $50,000,000, of which Mr. Ford will have the benefit for approximately 100 years at 4 per cent. The company is, of course, bound to keep Nitrate Plant No. 2 in a condition to produce explosives, which, as a matter of preparedness, is of great value to the government, as no doubt a plant fully organized and in production would be available far sooner than one maintained merely in standby. Nevertheless Mr. Ford is offering but $5,000,000 for the title to the two nitrate plants, the Waco Quarry, the Gorgas-Warrior steam plant, transmission lines and appurtenances. That you may the better understand the value of the property for which Mr. Ford is offering this $5,000,000 I am attaching to this letter, as Exhibit "A," a brief statement prepared by the Chief of Ordnance showing the cost and estimated salvage value of these properties. From the table contained in this statement it will be seen that these properties cost the United States approximately $85,000,000 and that as scrap they are estimated to be worth $8,812,000. However, the last column of the table in Exhibit "A" indicates that the Chief of Ordnance believes the War Department can dispose of the property for $16,272,000. Mr. Ford is bound by his proposal to operate Nitrate Plant No. 2 but there is no legal obstacle to prevent his disposing of the other properties to which he gets title. Should he be able to obtain what the Chief of Ordnance estimates that the government can secure for the various items—namely, $3,000,000 for the Warrior plants, which have an installation of 40,000 hp., and $600,000 for Nitrate Plant No. 1 and dispose of the Warrior-Muscle Shoals transmission line, as a transmission line and not as scrap, for $675,000, and should he obtain $357,000 for the Waco Quarry, he would have left the Nitrate Plant No. 2 with its 80,000-hp. steam plant at a cost to him of less than $400,000. The interest on the proceeds of such possible sales would amount to a very large sum during the term of the proposed contract. The present revenue from rental of the power plant at Nitrate Plant No. 2 is a minimum of $120,000 per annum with a possibility that, in event of operation, it may run to $260,000. The cost of maintenance of Nitrate Plant No. 2 was approximately $200,000 during the fiscal year 1921. The total horsepower developed by the three steam plants to which Mr. Ford will get title is 125,000, which practically doubles the all-season or primary horsepower to be developed at Dam No. 2 (approximately 500,000 of the horsepower that is to be developed at Dam No. 2 will not be available 365 days in the year).

Congress Must Decide

Inasmuch as I am without authority in law to accept Mr. Ford's offer or dispose of the property as a whole, either by sale or by lease, it is peculiarly the province of Congress to weigh the considerations which will pass to the respective parties to the proposed arrangement, and to determine whether or not the advantage to the government in having Nitrate Plant No. 2 maintained in readiness for the manufacture of explosives and in actual production of fertilizer, together with the improvement to navigation, is of sufficient importance to justify the proposed departure from the present policy of the law in regard to dealing with the water-power resources of the nation and to warrant leasing to Mr. Ford government property for so long a period at the rental proposed.

Modifications of Offer Suggested

If Mr. Ford's proposal be accepted by Congress I suggest that there should be certain modifications made to safeguard the government's interest. As heretofore stated, there should be some assurance that the contracts made by his proposed company will be carried out.

I also suggest that the cost of acquiring the lands and flowage rights necessary for Dam No. 3 should be included in the sum upon which Mr. Ford is to pay 4 per cent interest as rent. The omission of the cost of these lands from this computation is more serious than would be the omission of the provision for a sinking fund, for the annual interest at 4 per cent on the cost of such lands and rights if used for that purpose would amortize a sum much larger than that provided for in paragraph 10 of Mr. Ford's proposal.

In case the proposed company sells any or all power developed at either or both of these dams it should be required to do so under terms and conditions imposed by the Federal Power Commission or the Public Service Commission of Alabama in the manner required of other power companies.

I believe it would be better policy to limit the contract to a term of 50 years to conform to the established policy of the Federal Government as set out in the water-power act. In my opinion a contract such as that proposed for a period of 100 years is not a wise general policy in view of the unknown possibilities surrounding water power developments and the probability of changes which may be made, especially in the transmission of power.

While paragraphs 4 and 8 of the present proposal provide that Mr. Ford's company is to pay to the United States

annually the sum of $35,000 on Dam No. 2 and $20,000 on Dam No. 3 for repairs, maintenance and operation of the dams, gates and locks, Congress may well consider whether it would be more desirable to have Mr. Ford maintain the property and omit these payments.

Wilson Dam Should Be Completed

If Mr. Ford's proposal be not accepted it is my opinion that Dam No. 2 (Wilson Dam) should be completed by the government and that the power requirements for commercial purposes, the benefits to navigation, as well as the possible needs of the government, would warrant this expenditure. If this were done the government may itself undertake to sell the product to the best advantage. In such case the amount of the government's present proposed investment would be very materially reduced, because Dam No. 3, costing from $18,000,000 to $25,000,000, would not be built. At Dam No. 2 it would not be necessary to make the full installation of power plant until the market should require such installation. This partial installation would effect a saving of present investment in at least the sum of $3,000,000, leaving, according to the Chief of Engineers' estimate, not to exceed $22,000,000 to be invested by the government at this time instead of $40,000,000 to $50,000,000. The analysis made by the Chief of Engineers (hereto attached as Exhibit "B") shows a loss in excess of $15,000,000 due to delay in the receipt of returns from rentals. Such a large loss would hardly be justified in case the investment is to ultimately bear but 4 per cent interest if there were not other considerations which are beneficial to both the government and the people of that vicinity.

Will Help Labor Situation

At this time when there is a large amount of unemployment it is not without importance to consider the advantage to the nation of the employment of the large amount of labor required in undertaking this development. I therefor urge that Congress give early consideration to this matter not only to settle a controverted question but to furnish employment on a large scale.

Chief of Ordnance's Opinion

In summarizing the Ford offer from the standpoint of the Ordnance Dept., Major-General Williams states that acceptance has the very important advantage of materially assisting in the development of nitrogen preparedness and has the disadvantages of conflicting with the contractural obligations with the American Cyanamid Co. and the Alabama Power Co. and of making a net return to the government of less than $5,000,000 for properties which have an estimated salvage value of some $16,000,000.

The difference, $11,000,000, appears therefore to be the price which the United States is paying for nitrogen preparedness. If the plant is diverted to any purposes which do not include nitrogen fixation, this asset is lost to the government.

Chief of Engineers' Opinion

Major-General Lansing H. Beach summarizes the indirect benefits accuring to the United States on acceptance of the offer to be as follows:

(*a*) The maintenance of a nitrate plant in readiness for a war emergency.

(*b*) The production, in the interest of the public welfare, of large amounts of fertilizer at a cost not exceeding the reasonable cost of production, providing that the production of nitrate adapted to fertilizing purposes is found to be practicable.

(*c*) The elimination of the cost of maintaining and operating the present imperfect facilities for navigation at Muscle Shoals, amounting to from $35,000 to $85,000 per annum.

(*d*) The advantage to interstate commerce and navigation of the far superior facilities to navigation that will be secured through the construction of the dams and locks.

The funds that have been expended on Dam No. 2 have not been included in the analysis, for the reason that neither the acceptance nor the rejection of Mr. Ford's offer would restore any substantial portion of them to the public treasury. If Dam No. 2 be not completed, either by Mr. Ford's company, the United States, or otherwise, the work done will be wholly without value within a brief period of years, and the only recovery possible from the investment already made will be the scrap value of such machinery as can be disposed of, too small in amount to affect the present analysis.

Rate Relief on Basic Commodities Urged by Hoover in Railroad Statement

The statement of Secretary Hoover to the Interstate Commerce Commission on Feb. 3, in which he laid before the Commission what is believed to be the Administration's idea as to how railroad rates may be reduced without serious injury to the carriers, is of interest alike to producers and consumers of chemical and metallurgical products. Mr. Hoover's statement was studiously prepared and it is believed that his recommendations will be given careful consideration by the Commission.

In advocating reductions in rates on basic commodities, a view that President Harding has maintained, Mr. Hoover treated the whole subject from a point of view of full sympathy for the railroads and the fundamental dependence of the country on railroad transportation. He urged reduction of railroad operating costs and restoration of credit so that the railroads might expand.

"One thing is absolute," declared Mr. Hoover, "Our transportation facilities are below the needs of our country, and unless we have a quick resumption of construction, the whole community—agricultural, commercial and industrial—will be gasping from a strangulation caused by insufficient transportation the moment that our business activities resume. For the past 5 years, we have had no consequential expansion to our railway transportation machine.

Railroad Construction Necessary

"I wish to emphasize that unless we can have an immediate resumption of construction and equipment, our commercial community will pay treble the cost of the whole of them in their losses of a single season. The very moment that we reach anything like normal business we shall see a repetition of car shortages, followed by an increase in the cost of coal to the consumer from $1 to $3 a ton; we shall again see premiums of 20 cents a bushel for the use of cars for moving grain; we shall in fact see a shortage of commodities to the consumer; and we shall see gluts upon the hands of the producers. We shall see factories filled with orders again closed for lack of cars; we shall see large intermittency in employment; and we shall see the usual profiteering in commodities due to a stricture between the producer and consumer.

Urges Freight Rate Reduction

"If I were to discuss the rates charged today I should say at once that a decrease in passenger rates is not nearly so vital to the community as freight rates, for passenger rates do not enter into the 'spread' in proportion to the relative volume of earnings. If I were examining the freight rates, I should at once say that coal, metals, wood and agricultural and other producers' goods should be reduced to the bottom before less than carload lots and class rates are touched.

"I would be willing to go even further and say that I am convinced that even if the Commission cannot at the present moment justifiably reduce railway incomes a single dollar, it is warranted in investigating the possibility of some relief to the more distressed commodities by a revision of some rates upward. There is perhaps no great field for changes in this direction, but it is worth inquiry. As mentioned above, an economic analysis of our industry will show that less than carload lots and class rates are far too low compared to the rates on primary commodities.

"With the gradual return of the traffic to normal, with decreased operating costs, relief in rates will be available, and it would be an economic crime to apply such relief by horizontal reductions to all rates, thus giving relief to higher priced goods and travel, when the vital mainspring of our economic life, our agriculture and fuel and metals, are choked."

Technical News of the Week

Current Events in the Chemical, Metallurgical and Allied Industrial Fields—Legislative Developments—Activities of Government Bureaus, Technical Societies and Trade Associations

Industrial Developments of the Week

Glass. The Macbeth-Evans Glass Co., Elwood, Ind., has started up eight additional furnaces at its plant, giving employment to an increased working force.

The American Window Glass Co., Farmers' Bank Building, Pittsburgh, Pa., with plant at Arnold, Pa., is operatng at about 60 per cent capacity, with expectation of early increase.

Leather. The Standard Kid Co., Wilmington, Del., has resumed operations at close to full capacity, with production totaling about 750 dozen skins per day.

The Liberty Morocco Co., Wilmington, Del., has recently resumed production at its plant.

The Martin Leather Co., Wilmington, Del., is operating at close to regular capacity at its local plant.

Cement. The Lehigh Portland Cement Co., Ormrod, Pa., has resumed production at its Mill F, following a period of inactivity. The company is planning for the early reopening of its Mill D, in the same vicinity.

The Coplay Cement Mfg. Co., Coplay, Pa., is arranging for the immediate resumption of manufacture at its Mill C, following an idle period.

Rubber. The Electric Hose & Rubber Co., Wilmington, Del., is maintaining capacity production at its local plant, and has orders on hand to insure continuance at this rate for several months to come.

Powder. The du Pont Powder Co., Wilmington, Del., will increase production at its plant at Carney's Point, N. J., to handle an order received from the Argentine Government for 1,000,000 lb. of smokeless powder, insuring a high rate of manufacture at the plant for a number of months to come.

Oil. The Fort Worth Cotton Oil Co., Fort Worth, Tex., has reopened its plant at Niles City, near Fort Worth, following a period of curtailment, giving employment to about sixty men.

Tin. The Fallcon Tin Plate Co., Niles, Ohio, has resumed operations at its mill at Canton, Ohio, formerly the plant of the Carnahan Tin Plate & Sheet Co.

The American Sheet & Tin Plate Co., Sharon, Pa., has placed additional hot mills in operation at its Mercer works, putting the plant on a full capacity basis. The company has also resumed full operations at its plant at Farrell, Pa.

The American Can Co., Chicago, Ill., is operating eighteen of its nineteen plants in this section, despite the fact that this normally is a low production period. About 10,000 workers are employed. It is expected to increase production considerably during the next 60 days.

Iron and Steel. The Bethlehem Steel Co. has placed another open-hearth furnace in operation at its Steelton, Pa., works, effective Jan. 30.

The Republic Iron & Steel Co., Youngstown, Ohio, is operating two merchant bar mills at its plant following an extended shut-down.

The Allegheny Steel Co., Brackenridge, Pa., has reopened four hot mills at its local plant, following a suspension of about a year.

The Newton Steel Co., Newton Falls, Ohio, has all of the ten hot mills in operation at its local plant.

Miscellaneous. The Newport Tar & Turpentine Co., Pensacola, Fla., has resumed operations after a shut-down of over a year.

Following a shut-down since December, 1920, the Grasselli Chemical Co. is arranging for the early resumption of operations at its plant at Terre Haute, Ind., giving employment to about 450 men. Production will be concentrated upon metallic zinc. A coal mine is now being opened by the company in this district to be used exclusively for company plant service, with capacity of about 1,000 tons per day.

The Peet Brothers Co., Kansas City, Mo., manufacturer of soaps, is operating its plant at close to normal, giving employment to the regular working force.

The Corn Products Refining Co., Kansas City, Mo., has commenced filling the elevators at its new plant at North Kansas City, which has been in course of construction for about a year past, and will place the works in full operation at once.

Finance Committee Hearing Shows Sentiment Favoring American Valuation

It is generally believed by those who attended the special tariff convention of the National Association of Manufacturers in Washington, Jan. 30 and 31, that the American valuation plan will be indorsed by the Senate Finance Committee.

The delay on the part of the Finance Committee in agreeing to the plan laid down in the bill passed by the House of Representatives has been due to the determined opposition of two Republican members of the committee. This was revealed when delegations of manufacturers called on the Senators and Representatives of their respective states. The names of the two Senators who are held to be responsible for the delay were not disclosed.

The gathering of several hundred manufacturers from all parts of the country demonstrated that there is little division of opinion among them as to the necessity for levying the ad valorem duties on American prices. This opinion is so universally held from the fact that manufacturers generally believe that no equitable foreign value can be arrived at with currencies in a jumble and with opportunities favoring more than ever the undervaluation of foreign-made goods.

The convention listened with careful attention to a detailed statement by H. E. Miles, of Racine, Wis., who appeared in opposition to American valuation.

Undervaluation by Foreign Producers

One of the most significant features of the convention was the establishment beyond any reasonable doubt that undervaluation and fraud are practiced to a very considerable extent by many foreign producers. The testimony of men who have first-hand information in this connection was convincing on that point. Among the others who brought out that phase of the situation was William Burgess, of the United States Tariff Commission. He told of several trips which he had made abroad to investigate fraud in the valuation of commodities intended for sale in the United States. The extent of undervaluation "went far beyond my anticipation or greatest guess," he said.

"The great body of the importers," continued Mr. Burgess, "is just as honest as the great body of manufacturers, but one dishonest importer can have a very demoralizing influence. He can import his goods, valuing them at a price that will demoralize the other importers and compel them either to go out of business or to follow his example. I have made six trips to different parts of Europe and another to the Orient to look into the matter of valuation. I was made to realize the impossibility of finding true foreign market values. On one trip I developed the fact that I could not get a wedge into any information for 2 months after my arrival. Afterward I found that it was on account of a ring, tied up with certain officials of our own government, who had advised the manufacturers on the other side that I was coming over and to look out for me. I had a commission from one of the largest houses in this country to make such purchases for their account

as to establish a true wholesale selling value abroad. The man who was honestly endeavoring to find out the prices and purchase the goods for me was boycotted. Orders were issued from New York to see that he got no more goods. Every manufacturer in that line in France, in Germany, in Holland and in Belgium refused to sell him goods. He was ruined financially."

Walter Camp, of Connecticut, in the course of his remarks said: "This is the Garden of Eden. This is the place where they all want to come. This country is the place where they want to fish and they want us to cut bait. Do not be deceived by those who are interested in telling us that we must have a big export trade now that our factories are so expanded. Do not follow false counsel and let those who give it come in behind you and take the domestic trade which constitutes 90 per cent of our business, while you are chasing poor credit customers who consume 10 per cent of our output."

It was contended that the American valuation plan is only a form of administration and has nothing to do with rates. It was declared repeatedly that it is the only recourse against fraudulent valuations and is absolutely necessary to break up the practice of manufacturers who ship their goods to themselves in this country. If a manufacturer invoices goods to himself he can value it at nearly any price that he may choose, it was declared.

Impossible to Get Foreign Values

One of those who spoke told how the Board of Appraisers at New York had sent a highly qualified agent to Germany in an effort to get the proper value of the German product. He went to the manufacturing town and endeavored to get the value. His presence was discovered and both the mayor and the chief of police advised him to leave the town as soon as possible. In fact he was followed through the streets and was branded as an American spy. He was denied all information. This was cited as characteristic of the difficulty in establishing values in a foreign country.

Herbert J. Wynne, of Rochester, N. Y., told of a trip he made to Germany last October. Out of 400 first-class passengers, 300 were men headed for Germany to buy anything they could buy. One of the passengers confided to Mr. Wynne that he had a letter of credit in his pocket for $250,000 and he expressed the hope that he would be able to spend every cent of it in Germany. "You know you get very intimate on shipboard," said Mr. Wynne, "and I was told more tricks than I ever believed existed. I was told how to cheat the United States Government and particularly how I could cheat the German Government."

Mr. Miles, who appeared in opposition to American valuation, pointed out that it would take a duty of 500 per cent to protect some specialties, as, for example, the cutlery industry, and that it would be necessary to cut loose forever from England, our greatest buyer; from Canada, our second greatest buyer, and from all the peoples with whom we fought in the war. "Prices of 329 different articles retailed in stores increased 260 per cent from 1914 to 1919," Mr. Miles said. Under American valuation the tariff would go up 260 per cent. He urged that the tariff be handled so that the people will respect it and not turn on it and force it down to an unreasonable level.

Rochester Section, A.C.S., Hears Chemical History

"The Chemical Awakening of America" was the topic of an address delivered before the Rochester Section of the American Chemical Society, Jan. 23, by W. J. Hale, director of the research laboratory of the Dow Chemical Co. To show how America has reached her present place in the science Dr. Hale traced briefly the history of chemistry from the early Egyptian efforts through the successive eras to the present time. He pointed out that Germany awakened in 1875 to the need for quality production, but that it took the world war to arouse England and America to the importance of quality as well as quantity production, a fact which is responsible for the present keen competition from German goods.

Plea for Reduction of Freight Rates Advanced by Manufacturing Chemists' Association

The Manufacturing Chemists' Association has adopted resolutions calling for a percentage reduction in freight rates by the Interstate Commerce Commission.

In hearing fertilizer interests in its investigation of the rate situation, the Commission was requested by these interests to make a 25 per cent reduction in the rates on fertilizer materials and on the complete fertilizer. It was argued that fertilizer is a necessity in the agricultural industry and the lower freight rates would increase production and thereby reduce prices.

The Manufacturing Chemists' Association requested the Commission to make a horizontal reduction in the rates the same as they had been increased, applying to all classes and commodities. It was pointed out that in the last 5 years the freight rate increases applying to fertilizer and its materials when compounded represented an advance of more than 100 per cent over the rates prior to 1916.

Agricultural and Fertilizer Interests Record Opposing Views on Muscle Shoals

The sentiments of those favoring the acceptance of the Ford offer for the Muscle Shoals plant are epitomized in a resolution adopted by the National Agricultural Conference, the text of which follows:

> To accomplish results without any further delay whatsoever, we urge the Secretary of War to recommend and the Congress to accept Henry Ford's proposal to take over the hydro-electric power and air-nitrate plant at Muscle Shoals, under a guarantee to operate same for 100 years at its present capacity of approximately 100,000 tons of ammonium nitrate per annum, opening the Tennessee River to navigation, cheapening the production of fertilizer, metals and other commodities, and assuring the United States nitrogen independence in peace or war.

Charles H. MacDowell, president of the National Fertilizer Association, in opposing the resolution endeavored to make clear the basis of the opposition of the fertilizer industry. "Inasmuch as this resolution specifically refers to the fertilizer industry," he said, "and as the press has recently stated that the impression prevails in certain quarters that the fertilizer industry was maintaining a lobby to prevent development of the Muscle Shoals projects, it is only fair for me to state that the fertilizer industry is opposing some of the features connected with this matter, but that it is doing so openly over its own name in the publicity it has disseminated, and I also am now speaking openly that there may be no doubt that our opposition is above board and entirely proper.

Questions Soundness of Accepting Ford Proposal

"The fertilizer industry, as far as I know its position, is in favor of the development of navigation on the Tennessee River and the construction of a hydro-electrical plant, providing it is carried out along sound engineering and financial lines. It does, however, question the soundness of the suggestion that large sums of government money be utilized in developing a project to be leased at an unknown rate of return on the final cost, when the total capital expended is for the benefit of an individual over a period of 100 years or more, as against the 50-year limitation of the national water-power bill. It feels that it is not fair that an individual should be given a monopoly on the use and sale of this electric power over that period, permitting him to profit largely in the disposal of the power to farmers, to small town and city consumers and giving him a power production cost on his own industrial activities so low that he would be placed in position to compete unfairly in the markets of the country, not only on fertilizer, but on other basic productions, as against those industries operating on their own capital and at materially higher cost.

"There has been much talk about the production of this plant, and the word 'nitrates' is generally used. The farmer when thinking of nitrates has in mind 'nitrate of soda,'

a product which comes from Chile. This plant would not make nitrate of soda, nor would its operation do away with the necessity for nitrate of soda in agriculture and for other purposes, inasmuch as it has its own peculiar value. The credits derived by Chile from its sale are also their dollars to buy flour, meats, boots, shoes and the Yankee notions from the United States. The product which the plant was designed to make, and I am quite familiar with its development, was ammonium nitrate, a high explosive, very concentrated, absorbing moisture, difficult to handle, and not generally suited for fertilizer manufacture.

"While the capacity of the nitrate plant at Muscle Shoals is large, the 100,000 tons it is proposed to manufacture there would provide nitrogen in the grade of fertilizer best suited for cotton and general production for from three to four million acres of land. The territory adjacent to Muscle Shoals and which could be served from that point now has under the plow something like seventy-five million acres. It is evident that a wide distribution from that point could not be secured.

"The product which normally would be made at Muscle Shoals is sulphate of ammonia. During the war the United States Government financed the building of a number of byproduct coke plants, so that the ammonia production in this country increased from something like 250,000 tons to 550,000 equivalent. Only 135,000 tons of this was used by agriculture in 1920, and the manufacturers have been forced to find foreign markets in competition with the world for 130,000 tons in 1920, in which year they carried over 40,000 tons. It does not seem to the fertilizer industry that it is good economics to make a product at labor and material expenditure which is already largely overproduced.

"The fertilizer industry does not make sulphate of ammonia. It is a buyer of this product, so that this proposed production is not directly competitive with the fertilizer industry.

"The fertilizer industry feels that the operation of the nitrogen-fixation plant at a time when there is such a serious overproduction is not sound.

"This is the position of the fertilizer industry, openly announced."

Society Offers Practical Aid to Glass Research

For the purpose of encouraging research work on glass the research committee of the Glass Division of the American Ceramic Society has made arrangements for providing glass of desired composition and desired form for investigators in this field. The material will be supplied free of charge and no limitations as to the nature of the research will be imposed. The recipients of the material will be under no obligations except that of publication of the results of their investigations.

Persons who are interested are requested to address their inquiries to one of the following members of the committee on research: E. C. Sullivan, Corning Glass Works, Corning, N. Y.; E. W. Washburn, University of Illinois, Urbana, Ill.; R. B. Sosman, Geophysical Laboratory, Washington, D. C.

Metallurgy Course Organized by Steel Society

Under the auspices of the Detroit, Mich., Chapter of the American Society for Steel Treating, a class in elementary metallurgy has been started at the local Cass technical high school. The first session was held on Jan. 31, and the classes will meet hereafter every Tuesday evening until next June. The work will consist of special studies, recitations and lectures.

Society for Steel Treating Changes Meeting Plans

The American Society for Steel Treating has changed the plans for its sectional meeting in New York on March 3, which will be held in the Hotel McAlpin instead of at the Engineering Societies' Building as previously announced.

Chemical Laboratory for Brown University

Plans have been entirely completed and bids taken for the erection of a new chemical laboratory at Brown University, Providence, R. I. The building will be three-story and basement, brick and fireproof construction, 50 x 224 ft. It is expected to commence work at an early date. Day & Clauder, Philadelphia, Pa., are architects for the structure, and French & Hubbard, Boston, Mass., engineers.

Personal

F. C. Clark has resigned his position as manager of the industrial paper section of the American Writing Paper Co., Holyoke, Mass., to become manager of the Pejempscot Paper Co., at Brunswick, Me. Previous to his connection with the sales department, Mr. Clark was for 2 years head of the department of technical control of the American Writing Paper Co. In recognition of his services to the Connecticut Valley Section of the Technical Association of the Pulp and Paper Industry he was tendered a dinner and presented with a set of golf clubs by his fellow members.

Mortimer E. Cooley, dean of the University of Michigan, is about to embark on a tour of the country in the interest of fostering unity among engineers. Dean Cooley is president of the American Engineering Council of the Federated American Engineering Societies and is striving to bring the concerted efforts of American engineers to bear on the problems of elimination of waste in industry, the establishment of a national department of public works, Patent Office reform and superpower development.

Elwood Haynes, metallurgist and president of the Haynes Automobile Co., Kokomo, Ind., was elected to honorary membership at the recent convention of the American Society for Steel Treating, Indianapolis, Ind.

Chester H. Jones has resigned his position as Industrial Editor and has been appointed Western business representative in the Chicago territory for Chemical & Metallurgical Engineering. His headquarters will continue to be in the Old Colony Building, Chicago, Ill. This transfer is in line with the policy of Chemical & Metallurgical Engineering to improve its technical service to advertisers and readers alike.

Dexter S. Kimball, dean of Cornell University and president of the American Society of Mechanical Engineers, will visit the Pacific Coast in May to promote closer harmony between engineers of the East and West in the attainment of engineering ideals.

Charles H. Smith has resigned his position as chemical engineer with the Chemical Warfare Service at Edgewood Arsenal to accept a chemical engineering position in the development department of the Goodyear Tire & Rubber Co., Akron, Ohio.

Henry Traphagen, consulting metallurgist of the Toledo Steel Castings Co., Toledo, Ohio, gave an interesting address before the members of the Detroit (Mich.) chapter of the American Society for Steel Treating at its January meeting, on the subject of "Fatigue of Steel."

Ernest T. Trigg, Philadelphia, Pa., head of John Lucas & Co., paint manufacturers, and president of the National Paint, Oil and Varnish Association, was a guest of honor at a banquet given by the Pittsburgh (Pa.) Paint, Oil and Varnish Club, Jan. 20, at the local Chamber of Commerce Building. His address was on "A Great Industry Realizing Its Opportunity."

Alan G. Wikoff, Assistant Editor of Chemical & Metallurgical Engineering, has been transferred to the Chicago office as Industrial Editor, succeeding Chester H. Jones, who has been transferred to the business department.

E. D. Winkworth, president of the Semet-Solvay Co., has been elected president of the Solvay Process Co., succeeding E. L. Pierce, who resigned on Jan. 31. Mr. Pierce also resigned his place as one of the vice-presidents of the Allied Chemical Co.

Obituary

Twenty-nine years of fruitful professional life and with nearly as many more which he could easily have counted upon! And yet today we record the passing of CHARLES BASKERVILLE!

It is doubtful if many chemists have been more widely known. It has been the writer's experience never to have mentioned Dr. Baskerville's name to a fellow chemist at home or abroad and have it received as that of one unknown.

The audience of a chemist is large. He deals in matters so vital to the everyday person and in facts so stimulating to the imagination that whenever one of our profession wishes to speak he receives a respectful hearing. Dr. Baskerville often had a message, and he spoke it so well that it went far and reached many. In addition, who in our circle has had a kindlier personality or was more of a man among men? One of his greatest pleasures was making and holding friends. One of the college group who have been doing what they could to help during these last few days said to the family, "We are merely the visible ones who represent almost an army anxious to help." Surely, his friends are a host.

If we look over his field of work, we are impressed with his versatility; he has written, in all, 186 papers. His first appeared in 1893 in the *Journal of Analytical and Applied Chemistry* and was entitled "Rapid Methods for the Estimation of Phosphorus in Titaniferous Ores."

It was in no limited field that he worked. Some of us prefer atomic weights, others do marvels in delicate analysis, and a lesser number are more interested in refining oil or developing a new electric furnace compound. His taste, however, made him interested in all branches. In his earlier years we find him investigating analytical methods, but if a list of his papers be consulted, it will be seen that since then he has shown his interest in almost every branch of chemistry. The following fields received special attention: Vegetable and mineral oils and their refining; lead coating; atmospheric pollution; oil shales; paper manufacture and the recovery of paper stock; textile fibers; rare earths; radio-activity; anæsthetics; utilization of surplus munitions (war gases).

In addition to his many recorded papers, there is a package a foot high to which he used to casually refer as "unpublished research."

His books are:

"School Chemistry and Key," 1898, B. F. Johnson.

"Radium and Radio-Active Substances, Their Application Especially to Medicine," 1905, Williams, Brown & Earle.

"General Inorganic Chemistry," 1909, D. C. Heath.

"Laboratory Exercises to Be Used With General Inorganic Chemistry" (with R. W. Curtis), 1909, D. C. Heath.

"Municipal Chemistry" (Editor), 1911, McGraw-Hill Co.

"Course in Qualitative Chemical Analysis" (with L. J. Curtman), 1910, Macmillan.

"Progressive Problems in General Chemistry," 1910, D. C. Heath (with W. L. Estabrooke).

"Anæsthesia" (with J. T. Gwathmey), 1914, Appleton.

Charles Baskerville was born on June 18, 1870, at Deer Brook, Miss. His father was Charles Baskerville, his mother Augusta Louisa (Johnston). He studied at the University of Mississippi, 1886-87; University of Virginia, 1888-90; Vanderbilt University 1891; University of North Carolina, B. S., 1892, Ph.D., 1894; Berlin University, Ph.D., 1893. In 1895 he married Mary Boylan Snow. He was instructor 1891-94, assistant professor of chemistry, 1894-1900, professor of chemistry 1900-04 at the University of North Carolina. From 1904 to the time of his death on Jan. 28, 1922, he was professor of chemistry and director of the chemical laboratories, College of the City of New York.

His wife, his son, Charles, and his daughter, Elizabeth, survive him.

He was a member of the Chemists' Club, American Chemical Society, Society of Chemical Industry, Société de Chimie Industrielle (vice-president of New York Section), Century Club, Engineers' Club, American Institute of Chemical Engineers, American Association for the Advancement of Science, American Electrochemical Society (chairman, New York Section), Washington Academy of Sciences, N. C. Academy; New York Academy of Sciences and a Fellow, London Chemical Society. He was also chairman of the committee on occupational diseases in the chemical trades, A.C.S., and of the American Committee on the Ramsay Memorial Fund, and was a member of the committee on atmospheric pollution, American Institute of Chemical Engineers.

DR. CHARLES BASKERVILLE

The writer is very glad to have this opportunity to record what many others must have experienced for themselves. In 17 years of close professional association, I have been with one of the most loyal friends, one whose personality so pervaded every part of our department, that even his passing has not removed his spirit from among us.

H. R. MOODY.

GEORGE R. COMINGS, U. S. assayer at the United States Assay Office, New York City, died on Tuesday, Jan. 17, at his home, 51 Quincey St., Brooklyn, N. Y., after being in the government service 48 years. Funeral services were held on Thursday evening, Jan. 19, and burial the following morning in Greenwood Cemetery. He was born in Cos Cob, Conn., June 2, 1860, received his education in New York City schools and obtained degree in chemistry from Cooper Union. Mr. Comings entered the Assay Office at the age of thirteen and worked under Dr. Torrey, the first assayer in the history of the office and who was succeeded by his son, Herbert G. Torrey, Mr. Comings succeeding the latter on Nov. 1, 1910. He had been in poor health since an illness of 6 weeks last summer. On Jan. 2, at the Assay Office, he suffered an attack of heart trouble which confined him to his home until the time of his death. Besides his widow he leaves one daughter, two sisters and one brother.

GEORGE C. SYKES, secretary of the Lehigh Portland Cement Co., Allentown, Pa., died at his home in that city, Jan. 23, at the age of forty-nine years.

A Survey of the Economic and Commercial Factors That Influence Trade in Chemicals and Related Commodities—Prevailing Prices and Market Letters From Principal Industrial Centers

Our Foreign Trade in 1921

Official figures recently announced by the Department of Commerce confirm the prediction that our total foreign trade in 1921 would show a larger percentage reduction than in any single year in the history of the country. The combined imports and exports, which had reached the peak value of 13.5 billion dollars in 1920, fell to less than 7 billion during the past year. This represents a decline of 45 per cent in exports and 52 per cent in imports as compared with 1920.

The excess of our exports over imports in 1921 had an approximate value of $1,976,000,000. As will be noted from the figures in the accompanying table, our favorable trade balance has shrunk to less than one-half that of 1919. However, it is still considerably above the pre-war average. Furthermore, during 1921 we imported gold and silver in excess of our exports to the extent of more than $679,000,000. This further reduces our net balance of exports of merchandise, gold and silver to $1,297,000,000. In 1919 the corresponding figure was $4,457,000,000.

TABLE I—COMPARISON OF IMPORTS AND EXPORTS OF MERCHANDISE, 1913-1921

(Figures in millions of dollars)

	Exports	Imports	Excess Exports
1913	$2,484	$1,793	$691
1914	2,114	1,789	325
1915	3,555	1,779	1,776
1916	5,483	2,392	3,091
1917	6,231	2,952	3,279
1918	6,149	3,031	3,118
1919	7,920	3,904	4,016
1920	8,228	5,278	2,950
1921	4,485	2,509	1,976

The contraction in the value of both imports and exports appears to have extended to practically every great group of commodities. The National City Bank has pointed out that the imports of raw materials show a decline of 53 per cent in total value, foodstuffs 63 per cent and manufactures 43 per cent. The relatively smaller decrease in manufactures is probably to be explained by the activity of importers bringing in manufactured goods in anticipation of the enactment of a higher tariff. On the export side, raw materials fell off 48 per cent, foodstuffs 33 per cent and manufactures 51 per cent.

The primary cause of this tremendous reduction is probably the word-wide fall of prices. The import value per unit of quantity is in many cases only about half the corresponding figure for the preceding year. Crude rubber, for instance, averaged 34c. per lb. over 1920 and only 14.3c. during the past year. Cattle hides entered at 19.3c. in 1920 and 11.9c. in 1921. In the chemical schedule equally striking examples may be noted. The import value of oxalic acid, the first on the list, fell from 34c. to 14.5c. per lb., fusel oil from 22.6c. to 18.6c., crude potassium chloride from $105 to $66.50 per ton, and the crude sulphate from $154 to $65.

CHEMICAL & METALLURGICAL ENGINEERING'S WEIGHTED INDEX OF CHEMICAL PRICES

Base = 100 for the year July 1, 1913, to June 30, 1914

This week	147.33
Last week	144.60
February, 1921	166
February, 1920	252
April, 1918 (high)	286
April, 1921 (low)	140

The continued rise in the price of linseed and cottonseed oils caused the rather unusual increase in this week's index number. Slightly lower prices for sulphuric, hydrochloric and citric acids, caustic soda, caustic potash and soda ash were not of sufficient weight to counterbalance the upward trend of the index number.

CHEMICAL IMPORTS AND EXPORTS

Our "chemical trade balance," however, has shown a slight improvement in 1921 as compared with 1920. In both years, however, the balances were "unfavorable"—that is, our imports of chemical products were in excess of our exports. This of course was the condition that existed prior to the war, but for the 4-year period 1916 to 1919 our export trade in chemicals quite materially exceeded our imports.

TABLE II—A COMPARISON OF IMPORTS AND EXPORTS OF CHEMICAL PRODUCTS

	Exports	Imports	Excess of Exports
1914	$27,079,092	$94,519,912	—67,440,920
1915	46,380,986	79,273,398	—32,892,412
1916	124,478,474	109,155,705	15,322,769
1917	187,890,822	124,800,762	63,090,060
1918	180,318,954	151,832,065	28,486,889
1919	133,739,066	126,048,538	7,690,528
1920	168,999,706	211,528,099	—42,528,393
1921	61,111,293	95,603,912	—34,492,619

The detailed statistics for the principal chemical products, as given in Tables III and IV, show that in general the quantities decreased as well as the values. The imports of "chemicals, drugs, dyes and medicines" entering free of duty fell from $145,585,995 to $66,767,678. The dutiable

TABLE III—IMPORTS OF CHEMICAL AND RELATED PRODUCTS, BY PRINCIPAL COMMODITIES, 1920 AND 1921

decreased in about the same proportion. The total exports of chemicals were valued at approximately $169,000,000 in 1920 and at $61,000,000 in 1921.

Perhaps the most significant feature of the incoming trade was the continued importation of large quantities of coal-tar products. Although of slightly smaller volume than in 1920, there were many noticeable increases. Phenol, benzene, creosote oil and coal-tar pitch were received in larger amounts than in the preceding year. Colors and dyes fell off only about 10 per cent in quantity. A rather unusual circumstance was that potassium-cyanide imports fell from 14,450,000 lb. to 3,775,000 lb., while sodium cyanide increased from 7,590,000 lb. to 8,707,000 lb.

The total exports of chemicals were valued at only about one-third those of the preceding year, and with the exception of two products, every article in Table IV showed a decrease. The two exceptions are in the case of benzene and ammonium sulphate. The former increased from 13,000,000 lb. to 71,850,000 lb.

A Record Production of Petroleum

The petroleum output of the United States in 1921 was the largest ever recorded and exceeds that of 1920 by over 26,000,000 bbl. of 42 gal. each. The U.S. Geological Survey announced that the total production was 469,639,000 bbl., which is more than double the amount produced in 1912.

It is estimated that the world's production will probably be in the neighborhood of 750,000,000 bbl., as compared with 695,000,000 bbl. produced in 1920.

The estimated consumption—i.e., deliveries to consumers—of domestic and imported crude oil during 1921 amounted to 525,407,000 bbl., as contrasted with 530,474,000 bbl. in 1920. Consumption for the year just ended, therefore, amounted to 55,768,000 bbl. more than the country produced.

Estimates of Daily Production

The American Petroleum Institute estimates that the daily average gross crude oil production in the United States for the week ended Jan. 28 was 1,415,950 bbl., as compared with 1,418,200 bbl. for the preceding week, a decrease of 2,250 bbl.

The following are estimates of daily average gross production for the weeks ended Jan. 28, Jan. 21, 1922, and Jan. 29, 1921:

DAILY AVERAGE PRODUCTION

(Figures in Barrels)

	1922		1921
	Jan. 28	Jan. 21	Jan. 29
Oklahoma	325,350	325,900	273,370
Kansas	83,100	83,350	85,075
North Texas	60,350	60,900	74,020
Central Texas	216,350	214,250	137,160
North Louisiana and Arkansas	129,150	131,400	82,225
Gulf Coast	107,450	107,400	116,920
Eastern	115,800	115,500	121,000
Wyoming and Montana	53,400	54,500	52,646
California	325,000	325,000	325,000
*Total	1,415,950	1,418,200	1,267,415

*Daily average gross production.

American Potash in 1921

The U. S. Potash Producers' Association, on the basis of statistics submitted by members of the association, has estimated that the total production of potash in the United States during 1921 was less than 25,000 tons of crude salts containing less than 9,000 tons of K_2O. This production is the lowest for any year since 1916.

The association points out that this was due to the almost complete failure of the market. Most of the Nebraska plants were closed down in January, 1921. One or two continued producing a small amount through the spring months, but in April the last of them quit and no potash has been produced in the Nebraska field since that date. In Utah the last production came in February, while the last primary producer in California closed its plant in June.

During the last 6 months of the year the only plants still operating, so far as known, were two or three of the cement mills and two alcohol distilleries. These turned out a relatively small tonnage, and in default of a market made no effort to produce to capacity.

January Business Failures Set New High Record

The total number of business failures reported to Bradstreet's for the month of January was 2,705, or approximately 11.5 per cent above the former record total reported in December, 1921.

The liabilities for January were $115,301,371, an increase of 42 per cent over those for December and 76 per cent more than for January a year ago. This is the largest total of liabilities ever recorded in January and second only to the monthly total of $172,675,890 reported in October, 1908.

The Rise in Foreign Exchange

Conditions in Europe have improved materially if we are willing to accept foreign exchange as an index. Since the review published in our issue of Jan. 25, the British pound has reached $4.33, which is higher than at any time during the past year. French francs at 8.39 cents as compared with 8.15 on Jan. 18 is also a marked gain. During the same period the Italian lire increased in value from 4.35 to 4.69 cents.

The underlying factors which are thought to be responsible for the stronger exchanges are the successful conclusion of the Arms Conference, the passage of the foreign debt and refunding bill, and the promising possibilities of the coming economic conference at Genoa.

Soap Makers Cited by Trade Commission

Two Chicago soap manufacturers have been cited by the Federal Trade Commission in complaints of unfair competition. These charges are based on preliminary investigations of the Commission and, as is usual in such cases, 30 days is allowed for the companies to file their answers. Thereafter the cases are set down for trial.

The complaints charge that the Crofts & Reed Co. and the Polonia Soap Co. used false brands on certain of their soaps. Thus, it is charged that "Olive Bouquet" and "Olive Castille" were used on soaps containing no olive oil, and "Medicinal Toilet Soaps" applied to soaps said to contain no medicine or drug.

The Break in the Crude Rubber Market

One of the outstanding developments of the last 2 weeks has been the phenomenal break in the crude rubber market. The price of spot smoked sheets dropped from 21c. a lb. to less than 16c. This is only 6c. above the record low price of 1920 and is the lowest price quoted since last summer. Those familiar with the trade attribute the break to the forced selling by the large London interests. Furthermore the imports increased considerably toward the end of the year.

On Feb. 2 plantation first latex crêpe was quoted at 15½c. and smoked rib sheets at 15¾c.

New York Market

NEW YORK, Feb. 6, 1922.

The market for general chemicals during the week was somewhat irregular, with a tendency to limit puchases to immediate necessities. Large consumers are practically the only buyers interested in round-lot quantities, but the producers are getting most of this business. Factors in chemical circles were elated over the report that one of the largest textile concerns contracted for 1,000,000 lb. of bichromate of soda for delivery this year. This is the largest domestic order recorded for this item in the past 12 months. The price said to be paid for the quantity was in the neighborhood of 7c. per lb. Resale bichromate was generally quoted at 7¼c. per lb. with reports current that odd lots could be purchased down to 7½c. Actual spot offerings are not very liberal and the general tone of the market is quite steady.

The outstanding feature of the week's activities was the remarkable rise in red prussiate of potash. There seems to be no relief from the acute shortage and it is doubtful if any stocks can be purchased in any direction. In one quarter it was announced that a bid of 55c. per lb. for a small quantity was turned down. The shortage is apparently as pronounced in the foreign markets as in local quarters. Sales of yellow prussiate of potash were reported at 25c. per lb. The demand has continued quite active for small lots from the consuming trades. Business in caustic potash, 88-92 per cent, was very quiet, with imported prices ranging from $5.80@$6 per 100 lb. There were occasional odd-lot sales recorded at a fraction below quoted prices. Shipment figures range from $5.70@$5.75 per 100 lb. Leading importers of carbonate of potash, 80-85 per cent, report sales at 4½c. per lb. It is possible that round-lot orders would bring about some price concessions. Material for shipment was offered at 4¼c. per lb. c.i.f. New York. Although transactions have been mostly for small quantities, a good consuming demand has been noted in this item during the past week. Sales of solid caustic soda were reported by leading makers at $3.50 per 100 lb. f.a.s. Some are inclined to believe that large quantity orders could be purchased at $3.45. Producers are quoting contracts at $2.45 per 100 lb., basis 60 per cent, for carload lots, f.o.b. works. Domestic producers of cyanide of soda are finding a steady market at the revised prices of 26@28c. per lb. for the 96-98 per cent grade. Imported material is offered at prices ranging from 22½@26c. per lb. depending upon the test. The American producers have recently filed a brief with the Senate Finance Committee asking for a 33⅓ per cent ad valorem duty on cyanides, but it is doubtful whether any such rate will be agreed upon by the committee.

Spot soda ash has continued to be quiet, and the market has not shown any appreciable change. Carload quantities have gone through as low as $1.70 per 100 lb., while smaller lots commanded as high as $2. Spot quotations on barium chloride have advanced sharply during the week and sales have been reported at $54 per ton for fair-sized orders. Domestic producers quote contracts at $52 per ton, while imported material is held at $54@$58 per ton on spot, depending upon the quantity. First-hand sales of bleaching powder at the works were reported at 2c. per lb., but it is intimated that a firm offer for a large-quantity shipment might bring shading. The consuming inquiry for additional lots is not as active as at the beginning of the year. The decrease in price and demand is probably due to the fact that paper mills contracted heavily for shipment prior to the close of last year. Producers of fluoride of soda have reduced prices to a level competing with foreign sellers. Material can now be obtained from domestic sources at prices ranging from 8@9c. per lb., depending upon the quantity. Citric acid was reduced 2c. per lb. by leading manufacturers. This is the first price cut recorded in about 9 months. First-hand quotations ranged from 45@46c. per lb., with resale material held around 42½@43c. per lb. The demand was moderate.

COAL-TAR PRODUCTS

The coal-tar products market during the past week remained inactive. Producers in many instances were revising prices to attract what little business might be obtained. The call for phenol has remained quite active both for domestic and foreign consumption and the market showed a steadier tone. The recent reductions in cresylic acid and other tar acids have brought out an improved inquiry from the consuming industries and indications in this direction are more encouraging. Benzene is still in limited supply on spot and makers are booking a good volume of business for shipment. Large producers offer cresylic acid, 95 per cent, dark, at 45@47c. per gal. and the 97-99 per cent, straw color, at 50@52c. per gal. First-hand sales of dip oil, 25 per cent, are going through at 26c. per gal. Smaller quantities command a slight advance. A moderate inquiry is reported. The benzaldehyde market appears quite steady with consumers calling for contract deliveries. First hands quote the U.S.P. at $1.30@$1.35 per lb. and state that the technical is moving on the basis of 45@50c. per lb. There has been no added interest in the market on beta naphthol and prices have been weaker in some directions at 29c. per lb. The general range is from 29@32c. per lb. Prices on dimethylaniline in the resale market have been as low as 38c. per lb. Makers are quoting 40c. but the keen competition for passing business has caused price concessions.

The Iron and Steel Market

PITTSBURGH, Feb. 3, 1922.

Taking the steel market as a whole there has probably been a slight increase in demand on the mills in the past week, but the condition remains disappointing from the viewpoint of late December. Then it was expected that there would be a quick revival after Jan. 1 to the stage of activity witnessed in October and November. The demand is not yet up to the level of that period.

Probabilities now are that it will require the approach of spring to bring the steel market up, in point of tonnage, to the stage of activity previously witnessed. In other words, the lull of December was not a pre-inventory lull but a winter lull. This is the natural explanation of what is observed. There is no reason for assuming that the fundamental conditions that make for steel demand have changed for the worse, for rather the basis for activity is more substantial. Nor can the buyers' attitude toward prices be used as an explanation for light demand. Buyers have been holding off for many months from making purchases that could be postponed and at no time have done more than buy to meet pressing requirements. They cannot become more conservative than they have been.

Operations at individual plants change so much, almost from day to day, that a close estimate of the average rate of operation of the industry is impossible, and even an approximation is not easy. In general it may be said that while the production of steel ingots was at a rate of 23,000,000 tons a year in October and November and at 20,000,000 tons in December, the production of January may not have been as heavy as that of December, while it is somewhat doubtful whether even February will show a return to the October-November rate.

Price Competition Strenuous

The much more strenuous competition that appeared early in January shows no abatement. It is not so much that new low prices are being made on large orders as that relatively small orders are being taken at prices that formerly ruled only on large lots. The mills are making concessions from the regular or open prices for smaller and smaller orders, until in some commodities the regular prices rule only on carloads, and in some cases less than carload lots go at the regular prices.

The regular or open prices for the principal steel mill products have not changed in the past 6 weeks, or since the formal reduction in wire products made by the leading interest, Dec. 21, but on account of concessions having extended to smaller orders the average price of the entire tonnage sold has been steadily declining.

Shading is of course not equal for the different products. Sheets are held quite steadily. Until a week or two ago they were held very rigidly, but now it appears there are occasional instances of small concessions being given, particularly on galvanized sheets. In wire products the regular prices are held on ordinary orders, while to large jobbers, in nails at least, a concession of 10 cents a keg from the $2.50 price is given. In bars, shapes and plates concessions are quite common on lots of over 100 tons, the regular price for all three commodities being 1.5c.

Demand for fabricated steel, while far from large, is perhaps above the expectations recently entertained. Demand for tin plate is quite good and a heavy tonnage year is assured. Standard steel pipe is doing fairly well. Oil country goods are out of season and whether demand will return in the spring to the 1921 rate depends largely on prices bid for oil by the refiners.

Pig Iron and Coke

The pig iron markets continue quiet and prices are not overly firm. Prices in the valley market are unchanged since the declines reported a week ago, standing at $19.50 for bessemer, $18 for basic and $19 for foundry, f.o.b. valley furnaces, freight to Pittsburgh being $1.96.

Connellsville coke continues in poor demand, with prices decidedly weak. One large operator has allowed two monthly adjustment contracts for furnace coke to lapse, being unwilling to meet prices (said to be below $3) quoted by others on February delivery. Foundry coke is doing about as well as formerly. The spot market remains quotable at $2.75@$2.90 for furnace and $3.75@$4.25 for foundry, according to brand.

The St. Louis Market

ST. LOUIS, Feb. 2, 1922.

The actual volume of business transacted during January of this year in the St. Louis district was far better than for the corresponding month of last year, and it is hoped that this increase will continue. Reports from some quarters are not so favorable. There have been very few price changes during the last period, which is due to the healthier condition of the market; furthermore, this condition indicates that there is more confidence.

Alkalis

The market on caustic soda has eased up somewhat, showing a decrease in price of from 40c. to 60c. per 100 lb. The 76 per cent solid in carlots can be had as low as $3.40 per 100 lb., f.o.b. point of production. Spot goods in less than carlot quantities are $4.25 per 100 lb., in 1- to 10-drum lots. Carload price of the 76 per cent flake caustic is $3.75 f.o.b. point of production. Drum lot prices range from $4.40 to $4.85, and in one or two instances the price quoted is $5. Spot goods are in fair demand, but little is being done in the way of purchases for future delivery. Along with caustic soda, soda ash has declined quite appreciably, with the 58 per cent now selling in spot market for $2.40@$2.75 in 1- to 10-bbl. lots. Carlots can be purchased for about $1.85 in bags f.o.b. point of production. Bicarbonate of soda continues stable at around $2.75 in 5-bbl. lots, delivered to buyers' order. Salsoda in single barrels stands at $2.15 per 100 lb.

General and Special Chemicals

Manufacturers of heavy commercial mineral acids report good business. Acid citric is still on the inactive list, with further reduction in price taking place yesterday. The demand for gallic acid and pyrogallic acid has been much better for the last few weeks than for some time past. Phosphoric acid continues to move in a lively way. Ammonia water, 26 deg., U.S.P., is in fair demand. Inquiries for ammonium sulphate are more numerous. Carbon bisulphide is very firm with a normal demand. Producers of sugar copperas report that the demand is far greater than the production, with the price ranging from $18 to $20 per ton, f.o.b. works. Cream of tartar continues to move through regular channels, while tartaric acid has shown an appreciable increase. Glycerine is holding firm at 16½c. in drums, with a steady demand. Further advances on this item would not be surprising. Hydrogen peroxide is moving in a routine way. A further reduction in the prices of strychnine alkaloid and sulphate took place last week. The demand is light. Sulphur commercial is moving slowly. Louisiana producers quote $15 per ton for crude sulphur, f.o.b. works; freight rate to the St. Louis market is $9.60. There has been no change in the zinc sulphate market, and a fair amount of business is being transacted, the price ranging from 3c. to 3½c. per lb., f.o.b. point of production.

Vegetable Oils and Naval Stores

The linseed oil market is completely in producers' hands. Contracts for future delivery are being ignored today, and spot goods are being held at 82c. basis raw oil. Turpentine continues firm, fluctuating from 93c. to 98c. for pure gum spirits. Some material has been sold on the market for the pure gum spirits at a figure within 1c. of Savannah market price. Castor oil is in good demand and the price is firm at 13c. in drums, 14½c. in cans and 12c. in quantities of 200 gal. or over.

Paint Material

The St. Louis lithopone market continues in a slump. With three lithopone manufacturing plants in this district, imported goods fill most of the orders. Barytes are moving fairly well at $23.50 per ton. Whiting, all grades at all prices, is being offered here, prices varying from $12 to $18 per ton in carlots.

General Chemicals

CURRENT WHOLESALE PRICES IN NEW YORK MARKET

		Carlots	Less Carlots
Acetic anhydride	lb.	..... –	$0.40 – $0.42

Coal-Tar Products

NOTE—The following prices are for original packages in large quantities:

Alpha-naphthol, crude	lb.	$1.00 — $1.05
Alpha-naphthol, refined	lb.	1.15 — 1.20
Alpha-naphthylamine	lb.	.27 — .30
Aniline oil, drums extra	lb.	.16½ — .17
Aniline salts	lb.	.24 — .26
Anthracene, 80% in drums (100 lb.)	lb.	.75 — 1.00
Benzaldehyde U.S.P.	lb.	1.30 — 1.35
Benzidine, base	lb.	.85 — .95
Benzidine sulphate	lb.	.75 — .85
Benzoic acid, U.S.P.	lb.	.60 — .65
Benzoate of soda, U.S.P.	lb.	.55 — .57
Benzene, pure, water-white, in drums (100 gal.)	gal.	.29 — .35
Benzene, 90%, in drums (100 gal.)	gal.	.27 — .32
Benzyl chloride, 95-97%, refined	lb.	.25 — .27
Benzyl chloride, tech	lb.	.20 — .23
Beta-naphthol benzoate	lb.	3.75 — 4.00
Beta-naphthol, sublimed	lb.	.65 — .67
Beta-naphthol, tech	lb.	.29 — .32
Beta-naphthyla mine, sublimed	lb.	1.50 — 1.60
Cresol, U. S. P., in drums (100 lb.)	lb.	.16 — .17

Industrial

Financial, Construction and Manufacturers' News

Construction and Operation

Arkansas

LITTLE ROCK—The Arkansas Platinum Development Co., P. O. Box 815, C. C. Williams, secretary, has tentative plans under consideration for the erection of a new ore-reduction plant for platinum and gold production. The company has extensive mining properties in this section.

EL DORADO—Fire, Jan. 18, destroyed a portion of the oil refinery of the El Dorado Oil & Pipe Line Co., with loss estimated at about $32,000. It will be rebuilt.

Connecticut

STAMFORD—The Segal Metal Products Co., Springdale, near Stamford, has awarded a contract to Tucker & Lewis, 103 Park Ave., New York, N. Y., for the erection of a new 1-story foundry, 45 x 81 ft., to replace its plant building recently destroyed by fire. Lockwood, Greene & Co., 101 Park Ave., New York, are architects. R. H. Schoell is general manager.

Delaware

WILMINGTON—The Wilmington Sugar Refining Co. has filed plans for the erection of the first unit of its new plant in the South Wilmington section, consisting of a 5-story building, 125 x 150 ft., estimated to cost close to $750,000. Foundation work for this and other plant units is well under way, and plans for the other buildings will be filed early in the spring. W. J. Wayte, Inc., 125 East Forty-Sixth St., New York, N. Y., is engineer.

Florida

CLERMONT—The Board of Trade is considering the establishment of a local plant for the manufacture of glass bottles and kindred products. A company will be organized to operate the property.

Illinois

EAST ST. LOUIS—The Obear-Nestor Glass Co., 25 North Second St., St. Louis, Mo., has awarded a contract to the Fred Gauschmetz Co., 501 North 18th St., East St. Louis, for the erection of a 1-story addition to its East St. Louis plant at Broadway and Belt St., to be used for the manufacture of bottles, etc., estimated to cost about $75,000. Joseph Nestor is president.

Indiana

CARBON—The Carbon Firebrick & Coal Co., 345 Lemcke Annex Bldg., Indianapolis, Ind., is considering plans for the erection of a new plant in the vicinity of Carbon, for the manufacture of firebrick and other refractory products, estimated to cost about $150,000, including machinery. E. E. Dean is president.

MARION—The Mileage Oil Co., Kokomo, Ind., is negotiating for the purchase of the property and business of the Service Oil Co., Marion, and upon acquisition, plans for extensive operations. The Service company has been operating under a receivership; the receiver will dispose of the property.

BLOOMINGTON — The Bloomington Brick & Tile Co., A. W. Beecher, president, is considering the erection of a new plant, on site about 12 miles north of the city. The plant will consist of a number of one-story buildings, and is estimated to cost about $200,000, including equipment. Preliminary surveys for the buildings are under way.

Kansas

WICHITA—The Western Art Glass Co., 331 North Market St., is considering the construction of a new 3-story works building, 75 x 140 ft., estimated to cost about $60,000. It is planned to cemmence work early in March.

Kentucky

PAINTSVILLE—The Big Sandy Oil & Refining Co. is perfecting plans for the construction of a new oil-topping plant, with initial capacity of about 100 bbl. A number of tanks for storage service will also be constructed. Ralph Stafford heads the company; M. B. Westcott is engineer.

Maine

GREENVILLE — The Great Northern Paper Co. is completing the construction of a new mechanical building at its plant, 116 x 225 ft., estimated to cost about $230,000. A portion of the structure will be used as a machine and repair shop.

Maryland

BALTIMORE—The American Oil Co., American Bldg., is planning for the erection of a new plant to cost about $200,000. A large steel tankage department will be installed. Plans will be drawn at an early date. Louis Blaustein is manager.

BALTIMORE — The Virginia-Carolina Chemical Co., Richmond Va., will hold in temporary abeyance the erection of its proposed new plant at Baltimore to be occupied by its affiliated organization, the Rasin-Monument Co., National Marine Bank Bldg., Baltimore, for the manufacture of fertilizer products. The latter company now operates a plant in the Curtis Bay section of the city. The building contract for the new plant was awarded recently to Huggar Brothers, Montgomery, Ala.

BALTIMORE — The Atlas Chemical Laboratories, Inc., Mosher and Bruce Sts., is planning for enlargements in its plant. J. E. Auld, Jr., is president.

BALTIMORE—The Prudential Oil Co., Keyser Bldg., has completed plans for the construction of a new tankage plant at Third St. and Fourth Ave., consisting of a number of steel tanks, estimated to cost about $80,000.

BALTIMORE—The Maryland Steel Rolling Co., 1410 Fidelity Bldg., recently organized with a capital of $1,000,000, will soon commence the erection of its proposed new plant at Dundalk, consisting of a main works, 65 x 330 ft., with electrically driven mills and oil-fired heating furnaces. It is proposed to develop an annual production of about 30,000 tons of bar steel per annum. R. S. Baldwin is general manager.

Michigan

MANISTEE—The Filer Fibre Co., has tentative plans under consideration for the erection of a new local plant for the manufacture of fine paper, to utilize the output of the fiber mills. The plant will cost in excess of $250,000, and is expected to give employment to about 150 men. P. P. Schnorback, manager of the company is in charge.

GRAND RAPIDS—The Wolverine Soap Co., Portland, Mich., has acquired property at Grand Rapids for the erection of a new 2-story plant, 50 x 70 ft., to be ready for occupancy in June. The present works will be removed to the new location. A. A. Meeth heads the company.

Minnesota

MORRIS—The Board of City Trustees, Dr. George W. Ceenty, president, has rejected bids for the erection of a new filtration plant for the municipal waterworks, and will call for new bids at a later date. C. F. Tweed, 1353 University Ave., St. Paul, Minn., is engineer.

Missouri

WEBB CITY—The Rock Hill Paint & Cloth Co., Ray Porter, president, is planning for the erection of a new local plant for the manufacture of paints, oils, etc., estimated to cost about $50,000.

Montana

MILES CITY—The Glengarry Mining Co., has acquired property at Laurel, Mont., as a site for the erection of a new smelting plant for treating the ores from its properties near Cooke City. It is estimated to cost close to $500,000, including machinery.

New Jersey

PATERSON—Fire, Jan. 27, destroyed a large portion of the plant of the Colrin Chemical Co., River Rd., East Paterson, specializing in the production of nitrate of iron and kindred products, with loss estimated at close to $200,000. The main building, 100 x 100 ft., was entirely destroyed. Frederick Colrin is head.

New York

NEW YORK—The Fleischmann Co., 701 Washington St., manufacturer of yeast, has completed plans and will commence the immediate erection of a new 3-story laboratory building, 52 x 165 ft., on Mott Ave. near 157th St., estimated to cost $150,000. Arthur B. Heaton, 52 Vanderbilt Ave., is architect.

BUFFALO—Fire, Jan. 25, destroyed a portion of the plant of the F. F. Dalley Co., 271-81 Military Rd., manufacturer of polishes, with loss estimated at about $75,000.

NIAGARA FALLS—The chemical laboratory in the local high school was destroyed by fire, Jan. 25, with entire loss of building and other departments estimated at over $250,000. The Board of Education plans to rebuild the structure.

North Carolina

CHARLOTTE—A complete chemical and biological laboratory will be installed in the new high school to be erected by the local Board of Education at Cecil St. and Elizabeth Ave., estimated to cost in excess of $300,000. H. P. Harding is secretary.

Oregon

PORTLAND—The Colby Compression Tube Co. has acquired property at East Third and Burnside Sts., for the erection of a new plant for the manufacture of rubber tubes and other rubber products.

Pennsylvania

PHILADELPHIA — The Pennsylvania Sugar Co., 1037 North Delaware Ave., has construction under way on a new 2-story plant, 70 x 175 ft., at Delaware Ave., and South Laurel St., estimated to cost $50,000.

STROUDSBURG — The Scott-Warman Glass Co., East Stroudsburg, is considering the rebuilding of the portion of its plant, destroyed by fire, Jan. 31, with loss estimated at close to $150,000.

SCRANTON—Fire, Jan. 27, destroyed a section of the plant of the Wickham-Branning Cut Glass Co., Gibson St., with loss estimated at about $50,000.

SPRING GROVE—The P. H. Glatfelter Co. has awarded a contract to the Aberthaw Construction Co., for the erection of a 1-story addition to its paper mill, 100 x 500 ft., and will commence work at once. J. A. Dempwolf, York, Pa., is architect.

Rhode Island

PROVIDENCE—The Davol Rubber Co., Eddy and Point Sts., manufacturer of rubber goods, has awarded a contract to Carl E. Carlson, 142 Atlantic Ave., for the erection of a two-story addition to its plant.

Texas

ROTAN—The Patton Cement Plaster Co., recently formed with a capital of $350,000, has completed plans and will soon break ground for the erection of its proposed new local plant, on property about 1 mile from the city. It will be equipped for a capacity of 400 tons of material a day and is estimated to cost in excess of $200,000. J. W. Patton is president, and E. W. Maben, secretary.

Virginia

SHAWSVILLE—The Kimbalton Lime Co., Shawsville, Va., operating a plant at Kimbalton, Va., is planning for the erection of two additions, with two new kilns, and auxiliary operating equipment. Richard K. Meade & Co., 11 East Fayette St., Baltimore, Md., engineers, will take bids at once.

WINCHESTER—The Cumberland Valley Fruit Products Co., recently organized with a capital of $100,000, is planning for the erection of a new local plant for the manufacture of vinegar and affiliated products. It is estimated to cost about $60,000. Boyd Richards is president, and Allen Bond, secretary.

Washington

SUNNYSIDE—The Big Y Fruit Growers' Association, C. H. Swigart general manager, is planning for the establishment of a local plant for the manufacture of lime and sulphur spray products for agricultural service.

Wisconsin

PARK FALLS—The Flambeau Paper Co. is having plans prepared and will take bids early in the spring for the erection of a new 2-story pulp mill to cost about $100,000, with equipment. A portion of the structure will be used for office service. Thomas W. Orbison, 812 College Ave., Appleton, Wis., is engineer. Guy Waldo is general manager.

New Companies

THE CARROLL MFG. CO., Boston, Mass., has been incorporated with a capital of $15,000, to manufacture fiber board products, leather specialties, etc. Carl H. Carroll, Arlington, Mass., is president.

THE SOLIDIFIED NAPHTHA CORP., 1209 Conway Bldg., Chicago, Ill., has been incorporated with a capital of $50,000, to manufacture naphtha products, vegetable oils and affiliated specialties. The incorporators are Otto E. Reitzman, Albert Emerson and Edsen Manierre.

THE D. P. CASE CO., New York, N. Y., has been incorporated with a capital of $100,000, to manufacture chemicals, colors, etc. The incorporators are L. S. Hirsch, E. Dreyfus and J. C. Guggenheimer. The company is represented by Guggenheimer, Strasser & Meyer, 27 William St., N. Y.

THE NATIONAL BRICK CO., Washington, D. C., has been incorporated with a capital of $75,000, to manufacture brick and other burned clay products. The incorporators are J. E. and Clyde C. Daley; and Alan S. Wolfe, 1612 Longfellow St., Washington, D. C.

THE RUBBER ACE CO. OF NEW ENGLAND, INC, Providence, R. I., has been incorporated with a capital of $100,000, to manufacture rubber products. The incorporators are George C. Clinton, James O. McManus and John J. Dillon, 192 Lockwood St., Providence.

THE BEAVER ENAMELING CO., Ellwood City, Pa., has been incorporated with a capital of $33,000, to manufacture enameled products. A. Largue May, Beaver Falls, Pa., is treasurer.

LEAS & MCVITTY, INC., 303 Vine St., Philadelphia, Pa., has been incorporated with a capital of $3,400,000 under Delaware laws, to manufacture leather products.

THE HIGHLAND LAKE PAPER CO., Framingham, Mass., has been incorporated with a capital of 6,000 shares of stock, no par value, to manufacture paper products. Daniel A. Donnelly is president; and James P. Welch, treasurer, both of Framingham.

THE LION OIL & REFINING CO., El Dorado, Ark., has been incorporated under Delaware laws with capital of $450,000, to manufacture refined petroleum products. The incorporators are George A. Todd, El Dorado; F. H. Thwing and E. D. Ellison, Kansas City, Mo. The company is represented by the Corporation Trust Co. of America, du Pont Bldg., Wilmington, Del.

THE ODORLESS BYPRODUCTS & REDUCTION CO., New York, N. Y., has been incorporated with a capital of $10,000, to manufacture fertilizers and affiliated products. The incorporators are T. E. Halle, J. L. Watson and F. H. Butehorn, New York. The company is represented by F. J. Knorr, Albany, N. Y., attorney.

THE MAL-ZEMA CHEMICAL CO., 1021 Calvert Bldg., Baltimore, Md., has been incorporated with a capital of $100,000, to manufacture chemicals and chemical byproducts. The incorporators are William I. Russell, John H. Zink, and Cornelius J. Hamilton.

THE GLOBE VARNISH CO., 1503 City Hall Sq. Bldg., Chicago, Ill., has been incorporated with a capital of $100,000, to manufacture varnishes, paints, oils, etc. The incorporators are Frank C. Wilkinson, F. A. Willenbrink and Herman Sander.

THE SUNOCO SERVICE CORP., Trenton, N. J., has been incorporated with a capital of $100,000, to manufacture petroleum products. The incorporators are Henry J. Baker, Clark L. Dickson and Frank M. Brown, Pear St. and New York Avenue, Trenton.

THE STROH PROCESS STEEL CO., Pittsburgh, Pa., has been incorporated with a capital of $5,000, to manufacture steel products. A. R. Bassett, Westinghouse Bldg., Pittsburgh, is treasurer.

THE METAL-DURO PAINT CO., New York, N. Y., has been incorporated with a capital of $10,000, to manufacture metal-protective paints, etc. The incorporators are G. H. McMillin, H. C. V. Christensen and E. L. Smith. The company is represented by J. L. Rosenberg, 15 Park Row, New York.

SIEGEL'S STOVE POLISH CO., 38-40 Sherman Ave., Newark, N. J., has filed notice of organization to manufacture polishes and kindred products. The company is headed by Fred Siegel, 483 Stuyvesant Ave., Irvington, Newark.

THE GULF PRODUCTS CORP., New York, N. Y., has been incorporated under Delaware laws with capital of $100,000, to manufacture sugar products. The company is represented by the United States Corporation Co., 65 Cedar St., New York.

GARLINGER & CO., INC., 207 West Franklin St., Baltimore, Md., has been incorporated with a capital of $100,000, to manufacture soaps, flavoring extracts and kindred products. The incorporators are Isaac T. Parks, Jr., Frank F. Ramsey and William H. Garlinger.

THE MICHIGAN-ILLINOIS PETROLEUM CORP., Room 1303, 5 North Wabash Ave., Chicago, Ill., has been incorporated with a capital of $500,000, to manufacture refined petroleum products. The incorporators are Glen H. Downes, F. W. Graham and Colfax Gibbs.

THE KLEANSTONE CO., Buffalo, N. Y., has been incorporated with a capital of $10,000, to manufacture cleaning compounds and other chemical products. The incorporators are C. T. and F. T. McCarthy, and G. F. Smith. The company is represented by John J. Brown, Ellicott Sq., Buffalo.

THE FAIRMOUNT LEATHER MFG. CO., New York, N. Y., has been incorporated with a capital of $20,000, to manufacture leather products. The incorporators are S. Fogel, I. Ehrich and H. Friedman. The company is represented by Leo Schafran, 51 Chambers St., New York.

THE HULL & COWAN CO., Jacksonville, Fla., has been incorporated with a capital of $100,000, to manufacture brick and other burned clay products. Henry H. Hull is president; Hugh B. Cowan, vice-president; and W. N. Mason, Jr., secretary and treasurer, all of Jacksonville.

THE HILLTOP OIL CO., Eureka, Ark., has been incorporated with a capital of $100,000, to manufacture petroleum products. The incorporators are H. D. Hever, W. R. Heekey and C. N. Stambaugh, all of Eureka.

THE STANDARD DRUG & CHEMICAL CO., 24 South Charles St., Baltimore, Md., has been incorporated with a capital of $100,000, to manufacture chemicals and affiliated products. The incorporators are Arthur W. Smith, Jules D. Fritz, and Herbert Gordon.

THE MOORE LEATHER CO., Boston, Mass., has been incorporated with a capital of $10,000, to manufacture leather products. C. T. Moore is president; William S. Liggett, vice-president; and Frederick N. Moore, Peabody, Mass., treasurer.

THE EMMERT MFG. CO., New York, N. Y., has been incorporated with a capital of $50,000, to manufacture gummed papers and kindred products. The incorporators are S. B. and E. Emmert, and L. Nissen. The company is represented by J. A. Morison, 41 Park Row, New York.

ULMAN BROTHERS, INC., 30 West Baltimore St., Baltimore, Md., has been incorporated with a capital of $10,000, to manufacture chemicals, chemical compounds, etc. The incorporators are Marx, Ferdinand L., and Joseph N. Ulman.

THE ALUNITE CHEMICAL PRODUCTS CO., Wilmington, Del., has been incorporated under state laws with capital of $500,000, to manufacture chemicals and chemical byproducts. The company is represented by the Colonial Charter Co., Ford Bldg., Wilmington.

THE MYZO MFG. CO., Pittsburgh, Pa., is being organized by Joseph A. and George T. McCleary, and James H. Corbin, to manufacture chemicals, chemical compounds, etc. Application for a state charter will be made at once. James P. Herron, 86 St. Nicholas Bldg., represents the company.

THE MARTIN OIL REFINING CO., Rooms 619-21, 608 South Dearborn St., Chicago, Ill., has been organized under state laws as a subsidiary of the Aluminum Chemical Co., address noted, to manufacture refined oil products. The incorporators are Clinton D. Martin, John A. Rowe and J. J. Cruews.

THE SOILAMIES PRODUCTS CORP., Allentown, Pa., has been incorporated under Delaware laws, with capital of $100,000, to manufacture cement products and affiliated specialties. The incorporators are Harvey H. Steckel, W. C. Senger and C. B. Roberts, Allentown. The company is represented by the Corporation Trust Co. of America, du Pont Bldg., Wilmington, Del.

THE LIBERTY SPARK PLUG CORP., Boston, Mass., has been incorporated with a capital of $75,000, to manufacture porcelain spark plugs. James E. Rich is president; and Richard J. Burton, Brookline, Mass., treasurer.

THE BIG SANDY OIL & REFINING CO., Paintsville, Ky., has been incorporated with a capital of $24,000, to manufacture petroleum products. The incorporators are Ralph Stafford and H. B. Stambaugh, of Paintsville; and H. B. Stafford, Ashland, Ky.

THE ROYAL BRASS FOUNDRY CO., 39-45 New York Ave., Newark, N. J., has filed notice of organization to manufacture brass, bronze and other metal castings. Lothar Elsner, 20 Beach St., Newark, heads the company.

Capital Increases, Etc.

THE LUTTER BRICK CO., 1445 Diversey Parkway, Chicago, Ill., has filed notice of increase in capital from $50,000 to $200,000.

THE SEIBERLING RUBBER CO., Akron, O., manufacturer of tires and other rubber products, has arranged for preferred and common stock issues to total $1,500,000, for additional working capital, general operations, etc. F. A. Seiberling is president and general manager.

THE GRAND RAPIDS VARNISH CO., Grand Rapids, Mich., has filed notice of increase in capital from $100,000 to $300,000.

THE SHASTA ZINC & COPPER CO., 25 Broad St., New York, N. Y., has filed notice of increase in capital from $25,000,000 to $30,000,000.

VALENTINE & CO., 456 Fourth Ave., New York, manufacturers of varnishes, colors, etc., have filed notice of increase in capital from $2,250,000 to $3,000,000.

THE MONTROSE REFINING CO., Shreveport, La., manufacturer of refined petroleum products, has filed notice of increase in capital from $1,000,000 to $3,000,000.

A petition in bankruptcy has been filed against the SPEARE CHEMICAL PRODUCTS CO., INC., 30 Cliff St., New York, N. Y., by a number of creditors.

THE DEFORD CO., Luray, Va., manufacturer of sole leather and other leather products, has arranged for a bond issue to total $600,000, the proceeds to be used for general operations, financing, etc. Robert B. Deford is vice-president.

Coming Meetings and Events

AMERICAN CERAMIC SOCIETY will hold its twenty-fourth annual meeting at St. Louis, Feb. 27 to March 3, 1922.

AMERICAN CHEMICAL SOCIETY will hold its spring meeting at Birmingham, Ala., April 4 to 7, 1922.

AMERICAN ELECTROCHEMICAL SOCIETY will hold its spring meeting in Baltimore, April 27, 28 and 29, 1922. Headquarters will be at the Emerson Hotel.

AMERICAN FOUNDRYMEN'S ASSOCIATION will hold its next convention and exhibit at Rochester, N. Y., during the week of June 5, 1922. Meetings will be held in the spring instead of in the fall as heretofore.

AMERICAN INSTITUTE OF MINING AND METALLURGICAL ENGINEERS will hold its spring meeting in New York the week of Feb. 20, 1922.

AMERICAN SOCIETY FOR STEEL TREATING, will hold a sectional meeting, Friday, March 3, at the Hotel McAlpin, New York City.

AMERICAN SOCIETY FOR TESTING MATERIALS will hold its twenty-fifth annual meeting June 26 to July 1, at Atlantic City, N. J. Headquarters will be at the Chalfonte-Haddon Hall Hotel.

INTERNATIONAL UNION OF PURE AND APPLIED CHEMISTRY will hold a meeting at Lyons, France, June 27 to 30.

IRON AND STEEL INSTITUTE (British) will hold its annual meeting on May 4 and 5 at the House of the Institution of Civil Engineers, Great George St., S. W., 1, London.

NEW JERSEY CHEMICAL SOCIETY holds a meeting at Stetters Restaurant, 842 Broad St., Newark, N. J., the second Monday of every month.

NORTHWEST MINING ASSOCIATION will hold a convention in the Chamber of Commerce Bldg., Spokane, Wash., Feb. 14 to 18.

STAMFORD CHEMICAL SOCIETY, Stamford, Conn., holds a meeting in the lecture room of the local high school on the fourth Monday of each month, except June, July, August and September.

The following meetings are scheduled to be held in Rumford Hall, the Chemists' Club, New York: Feb. 10—American Electrochemical Society (in charge), Society of Chemical Industry, Société de Chimie Industrielle, American Chemical Society, joint meeting; March 10—American Chemical Society, Nichols Medal; March 24—Society of Chemical Industry, regular meeting; April 21—Society of Chemical Industry (in charge), American Electrochemical Society, Société de Chimie Industrielle, American Chemical Society, joint meeting; May 5—American Chemical Society, regular meeting; May 12—Société de Chimie Industrielle (in charge), American Chemical Society, Society of Chemical Industry, American Electrochemical Society, joint meeting; May 19—Society of Chemical Industry, regular meeting: June 9—American Chemical Society, regular meeting.

A British View Of the Dye Industry

IT IS REFRESHING to observe the wholesome respect with which the policies of leaders in industry are being received. An industrial program based on strict observance of the principles of sound economics which a short time ago was a voice crying in the wilderness is now hailed as a master stroke in the "return to normalcy." Fable has it that it took the fall of an apple to demonstrate to NEWTON the truth of the law of gravitation. Evidently it has taken the collapse of the bubble of post-war prosperity to bring home to our industries the existence and operation of economic laws which had been lost sight of in the period of speculation and overexpansion during and immediately after the war.

Some industrial problems are local and some are worldwide. Those confronting Great Britain are similar to our own, although perhaps more serious in many cases. Railroad and freight rates are higher than they should be. The coal production is uncertain and prices for home consumption are variable. The labor situation is unsettled. The dye and chemical industries are threatened, but they have an able champion.

"Chemicals and dyestuffs form the two most important and valuable key industries that a nation can possess. They ought to be vigorously developed and closely guarded." Thus spoke Sir WILLIAM ALEXANDER, chairman of the British Dyestuffs Corporation, Ltd., in a statement given to *Chemical Age* (London), after an extended tour of the United States and Canada in the interests of the future of the British dye industry. He points out that Great Britain has facilities in modern equipment for supplying at least the requirements of the British Empire. These new and extended installations should not be permitted to become derelict, for they stand for national security as well as commercial prosperity. They can be maintained in operation if British consumers will support British industries, if British chemists and engineers will concentrate on obtaining maximum efficiency in their plants, if labor will recognize that maximum production is its best security for good wages, if the British Government will continue to assist the industries to fight against depreciated currencies and other handicaps to fair trading and if the government will send commercially competent consuls and trade commissioners to pioneer and assist in the development of British trade. The reconstruction of Europe is all-important to Great Britain as an exporting nation and Sir WILLIAM advocates the rendering of aid by solvent countries to assist in reconstruction on sound lines, but warns against trade with nations on hazardous credit.

Such a reconstruction policy is sound economics and applies equally well to the United States. The depreciated currency and phantom credit of insolvent nations should turn the body of trade of exporting countries within their own boundaries, thus insuring maintenance of production facilities and a circulation of money within the country—a condition which stimulates production and employment. Nations whose currencies have fallen so low as to have little or no purchasing power must suffer until they have reorganized their internal economies and industries by production so that exports may balance imports. Production is their salvation, and the sooner such reorganization is accomplished the sooner will those countries reach a stable economic condition. But for countries like Great Britain and the United States, which have balanced budgets and fairly stable business conditions, the great desideratum is the maintenance of those key industries like dyes and chemicals which have been built up at great cost under arduous conditions. We wish political leaders could see the light as clearly as business men.

In Full For Services Rendered

OUR comment last week on the soldier bonus has brought some friendly protest from subscribers who are members of the American Legion and favorable to bonus legislation. We did not expect that our opposition would meet with unqualified universal approval, but we felt that it was in the best interest of business and industry to sound a warning against increasing taxes at a time when the nation is already heavily in debt and its citizens are struggling under a burden of unprecedented magnitude.

There is no doubt in our mind that the country, as a whole, does not want bonus legislation. It is noteworthy that no public voice other than that of politicians and American Legion officers has been raised in its support. As far as we are aware, every newspaper of importance has expressed itself editorially against the proposal. The all-important question is, Where is the money coming from? We think it not unfair to call upon the American Legion to make some constructive suggestions in the solution of this problem. It is unfair to sidestep it. In trying to solve it, Congress is in the most desperate dilemma with which it has yet been confronted. Will the Legion openly sponsor additional taxes in any form: a sales tax, a stamp tax, a motor tax, a gasoline tax, new taxes on tobacco, postage and theater tickets? Will it advocate these things or any of them to the farmer, the small merchant or the salaried man? If it will undertake something definite of this kind, we believe it will soon discover just how unpopular the bonus measure is.

Elsewhere we publish a few letters inspired by our editorial comment of last week. One of our correspondents unfortunately argues for the bonus on the basis of "paying a debt to those who 'took a chance' against the German" and "sufficient recompense for the time

spent on military duty." The argument does not appeal to us, nor do we think it is the best that can be advanced. Will the American Legion, or any member of it, or our correspondent give a receipt to the United States "in full for services rendered," and acknowledge that he has been fully compensated by the payment of a sum ranging from $500 to $625? We think not. We hope not. No cash value can be placed upon the service rendered by those who wore the uniform in the late war, whether they helped build Muscle Shoals or fought their way through the Argonne.

It may be just as well to mention the fact that in opposing the soldier bonus we are not expressing the opinions of theorists. We speak as those having experience, if not authority. Five men on CHEM. & MET.'S staff served overseas and in this country. They came out of the war poorer than they went in. In no case did their war-time compensation amount to enough to take care of themselves and families and they were obliged to draw upon savings or to incur debt. But none of them is in favor of the bonus. They all realize that legislation for it would be an economic blunder.

Mysticism Among Men of Science

IT WAS NOT so very many years ago when most men of science were in open conflict with all that is mystic in life. We older fellows called it the conflict between Science and Religion—and so did Dr. DRAPER and so did Dr. WHITE of Cornell. It was a lively and rather bitter quarrel in which nearly everybody took side. The fight was hot and anger was rife, so that very few of the parties of either part could see that the dispute was not between science and religion, but rather between science and dogma.

It appears to us that a turn in the habits of thought of many men of science is coming about. They are not seeking the mourners' bench or weeping over their sins or singing revival hymns or even growing orthodox from the standpoint of dogma; but there appears to be coming over a considerable number of leading men of science an enlivened reverence for that which is beyond human knowledge. It shows itself in various ways. Sir WILLIAM CROOKES did, and Sir OLIVER LODGE does, believe in ghosts. They have not many followers among their colleagues. The tendency is rather toward a less definite quality of mysticism; toward a belief in a greater illumination than is ours. It is not organized and it does not follow creeds or catechisms or articles that were drawn and recorded when, according to the best human understanding, the earth was flat like a cake, when it was the center of the universe, when the sun was a great lamp that was raised in the morning and lowered at night, and the lesser lights, the moon and stars, were little incidents to mitigate the darkness.

Earlier generations accepted orthodoxy. Sir ISAAC NEWTON was a man of unusual piety. MICHAEL FARADAY was a sound churchman. LOUIS PASTEUR was among the last of the great men of science to whom the "requirements of faith" were welcome.

The present tendency is independent of dogma. It does not insist on any particulars. It does not condemn. It seeks the Greater Illumination and finds hope and comfort in the quest.

On January 8 last Professor MICHAEL I. PUPIN of Columbia made a memorial address at St. Paul's Chapel on the campus in honor of those who in their lifetime had advanced the honor of Columbia University. Now to such persons as know him casually, the genial professor of electromechanics would be about the last one they would expect to see in a pulpit preaching a sermon. But his beautiful "Herdsman's View of Human Life" was indeed a sermon. He harked back to the time when, 50 years ago, he had helped the village herdsman to guard the grazing oxen through the night on the hills of Serbia. The mystic thoughts of ancient reverence that inspired the watching boy have not been killed by the study of science. It was beautiful and reverent and sincere, and it did not offend the understanding. Many will remember the plea for spiritual vision made by Professor BASKERVILLE in his address at the Great Hall of City College during the September joint meeting of the chemical societies. It was his last public utterance, this urgent appeal for the search after light to come from beyond our ken. Dr. CHARLES P. STEINMETZ in his illuminating contribution to the current number of *Harper's Magazine* has approached close to the boundaries of mysticism.

It is an excellent thing to "get down to brass tacks" in our discussions of particular things and in the consideration of principles and processes. But the world is not made up of brass tacks alone. There are vague shapes in the minds of men and women that are potent to build up or to destroy. As men of science we are beginning to see that our obligations extend far and away beyond the laboratory, and that, among other things, the duty is ours to guide the vague shapes into the paths that lead to human welfare and betterment. We, too, are our brother's keepers.

X-Ray for Routine Testing

EVEN the best modern testing laboratories seldom possess X-ray apparatus, and it is still more rarely seen in use for the routine examination of chemical and metallurgical materials. But for that matter, only a few years ago a microscope was nothing but an instrument for advanced specialists, and the old ones among us can even remember the introduction of the analytical balances. So it is somewhat unsafe to prophesy the future utility of recently discovered and adapted implements of research when applied to the multifarious needs of present-day industry.

But based on past performances, some of which are well known, and on recent developments, not so widely advertised, the X-ray seems likely to become very useful in three major directions: First, for revealing sizable internal defects; second, for studies in crystallography; third, for spectrum analysis.

The first kind of work is an extension of the methods and equipment commonly used by dentists and medical men when they make shadowgraphs to aid in their diagnoses. A pencil of rays is passed through the body to be examined; the denser portions absorb or scatter a greater proportion, and cast a "shadow" on a fluorescent screen or photographic film placed beyond. In this way internal defects in solid material, improper material covered by veneer or contained in solid packages, and poor fits at joints can be easily determined in suspected articles, without destroying or even disturbing them in the investigation.

Notwithstanding the fact that such methods are thoroughly practicable for organic substances, they will require much development before they will be extensively used for testing metal. As a piece of steel becomes greater than 1 in. thick, the time of exposure

increases rapidly and the indications rapidly become less distinct. Of course, it is easily possible that the sensitivity of the fiber may be increased, some method of filtering out the confused beams scattered by the metal itself may be devised, and Coolidge tubes of very high power might be constructed. But even so, the physical danger attending the use of such penetrating rays and the enormous difficulties to be overcome at present seem to limit the use of pure radiography to moderate sections of metals of low atomic weight. Exposures of such castings, for instance, should show the presence or absence of dangerous blowholes or slag inclusions quite clearly. Unfortunately their cracks cannot be found unless placed "edge on" to the rays.

Crystallography is a subject which the ordinary testing engineer would associate with geology or mineralogy, and therefore quite anterior to the testing of materials in process. However, X-ray crystal analysis may easily become of great value in working with graphite, clay and various other substances entering largely into present-day industry but about whose chemistry and physics we are so relatively ignorant. A compact machine has recently been described in these columns for crystal analysis, and Dr. BAIN has shown how it has already yielded results of the greatest importance to theoretical metallurgy. Briefly, the method consists of passing a monochromatic ray through a sample of powder or fine-grained solid. The ray is photographed after reflection from the variously oriented crystalline planes. This reflection occurs in certain dominant directions which depend upon the atomic arrangement and which can be computed for the various crystal systems. Since no two substances have the same crystal structure, here is a new method of analysis. Unfortunately, it is not yet capable of showing small traces of adulterants. However, many substances of identical chemical composition exhibit isomerism and allotropy. Such a substance will exhibit many puzzling variations in its properties and action when in process, and yet the reason will of course be undiscoverable by chemistry and often elude other physical investigations.

True X-ray spectrum analysis may become more popular than the older visible spectrum analysis, because the number of X-ray waves characteristic of each element are very small and can be easily recognized. Furthermore, the intensity of the lines is strictly proportional to the amount of the element present. When practicable, the material to be investigated is rubbed into the face of the target in a Coolidge tube. X-rays emitted from this target are then analyzed by the X-ray crystal spectrometer, and the result compared with the radiations from the standard material—where only a comparative test is to be made—or to the characteristic waves for the various chemical elements, when an ultimate analysis is desired. Much the same results may be had by passing a pencil of X-rays from a tungsten target through a sample, and analyzing the emergent rays for absorption bands. This practice is particularly sensitive in detecting very small traces of heavy elements occurring in materials of low atomic weight.

Enough has been said in the above brief outline, however, to indicate that unquestionably the X-ray is a powerful tool, whose ultimate development and application cannot now be foreseen. Enthusiastic men in many laboratories will doubtless seize upon it now that the equipment has become available in compact and simple form, and adapt it to their own uses. What they will be able to do will be awaited with great interest.

Profits and Losses In the Steel Industry

THE "prince or pauper" industry experiences great vicissitudes in the matter of profits and losses, not simply because the demand for its product varies widely but also because it is subject to heavy overhead or fixed expense. The capital invested in facilities, excluding transportation facilities but including ore mines, coke works, blast furnaces, steel mills and finishing departments, is not far from $100 per gross ton of annual output in finished steel when there is substantially a capacity operation, so that there is an interest charge alone of something like $10 per ton on a 50 per cent operation. Then there are general administrative and selling expenses as well as a heavy expense in those employees at manufacturing plants who are naturally carried on annual salaries and whose employment does not vary according to tonnage output. Another fixed expense is taxes. This item cannot be estimated closely, but it is a matter of record that the United States Steel Corporation's taxes in 1920, exclusive of federal taxes, amounted to $38,724,289, the output of steel products for sale being 14,228,502 tons, representing an operation at 88.3 per cent of capacity. Allowing that part of the taxes accrued on transportation and other properties not engaged directly in steel manufacture, the direct taxes would be close to $2 a ton on a full operation, or twice as much per ton on a 50 per cent operation.

Given competitive conditions in the steel market, the free play of the law of supply and demand, with a demand less than 50 per cent of capacity, it is easy to see how the steel industry can quickly develop a condition of selling its product at a loss. The cost per ton mounts and it would require a high selling price to enable all producers merely to break even.

There were very few independent steel companies that did not report losses in 1921 and some of the losses appeared very large. The United States Steel Corporation reported earnings in both the third and fourth quarters of the year sufficient to pay all charges together with the preferred dividend, but with scarcely anything left for the common shares, on which the dividend at the modest rate of 5 per cent a year was maintained chiefly by drafts upon surplus.

A common view is that the Steel Corporation has such refinements and economies in operation that it can make profits when independent companies have losses, given similar conditions as to selling prices and rate of operation. This may be true, but the financial reports published do not prove the point, because conditions as to selling prices and rates of operation were not identical.

Even the Steel Corporation, however, is in a tight place as regards earnings. Superficially, the corporation seems to have done well when it reported earnings at $18,918,058 for the third quarter of 1921 and $19,612,033 for the fourth quarter, representing an increase of 3.7 per cent; but the showing is not as good as appears, since the earnings per ton greatly decreased, there having been an increase of 50 or 60 per cent in shipments from the third to the fourth quarter. Furthermore, the December shipments were at approximately the average rate for the quarter, while the December earnings were only $4,967,237, or at the rate of less than $15,000,000 for a quarter, instead of $19,612,033. Realized prices are probably running a trifle lower now than in December, while production is improved but little if any.

Readers' Views and Comments

Does Business Want the Soldier Bonus?

To the Editor of Chemical & Metallurgical Engineering

SIR:—I am not in the habit of writing with reference to editorials but I do wish to say that I feel a large percentage of the thinking men of the country are heartily in accord with the attitude which you have taken on the soldiers' bonus. I wish to extend to you my congratulations that you have the nerve to publish an article of this character.

At present I have in my department a few men who have been overseas, one of whom has suffered the loss of one arm. I think I am safe in saying that every one of these men who has seen actual service takes essentially the same attitude that you have in your editorial. I am speaking advisedly in this matter, because one of the strongest men in our school happens to be my personal assistant, an overseas man, who feels very strongly as you do, and knows the attitude of the other overseas men who are worth while.

Chemical Engineering Dept.,
Bucknell University,
Lewisburg, Pa. GLENN V. BROWN.

To the Editor of Chemical & Metallurgical Engineering

SIR:—I am always glad to recognize the courage of those who express their opinions at a time when such a statement may detract from their popularity and add nothing to their bank account; however, I wish to express an opinion contrary to the stand you have taken regarding the soldier's bonus.

It is my belief that not all the opponents to this legislation are as sincere in the cry for economy and their fear of national bankruptcy as you are.

The ex-service men of your acquaintance may be possessed of a super-patriotism that is not evident in western Pennsylvania, for I have not met a man who thought he had received sufficient recompense for the time spent on military duty.

Some of our self-styled economists have pointed out the advantage of paying still larger amounts to the railroads and the cancellation of the foreign debt; but the paying of a debt to those who "took a chance" against the German goes against their theory of economics and their morals.

We ask no favors, no courtesy, no preference; but only fair pay for a job which others have said was well done.

G. W. PAULIN.
Leechburg, Pa.

To the Editor of Chemical & Metallurgical Engineering

SIR:—I was greatly disappointed with your editorial in the current issue on the soldiers' bonus. I am proud to be a member of the American Legion and do not appreciate the implied slur on it, for it is an organization actuated by the highest ideals and one which is pledged to promote the best interests of the country as a whole. At the present time it appears that it is only just that those who spent time in the service of the nation should have some form of compensation to place them on a financial par with those who for one reason or another did not go. Most of the influential members of the American Legion are agreed that the cash settlement plan will be chosen by only a small proportion of the total number of eligibles and by even a smaller ratio of our members. However, you should know that we are undertaking a census to determine that matter accurately.

Bonuses were given freely to those who might otherwise have lost by cancellation of war contracts, to the railroads and to the civilian employees of the government. We do not say that these were not necessary and just, but we do claim that compensation for the veterans is not only just but will be a good investment for the future economic welfare of the nation as a whole, for it is so designed as to throw by far the larger part of the amount allowed into the purchase of homes and farms, the two types of investment which do most to promote stability and industry in society.

As a chemical engineer and an old subscriber, I hated to see you misled on this very important question and hope that you will get in touch with our national officers and get a definite and accurate line on the Legion aspirations before writing your next article on this subject.

Kansas City, Mo. R. H. BAXTER.

Human Relations in Industry

To the Editor of Chemical & Metallurgical Engineering

SIR:—Referring to the subject of "Human Relations in Industry," considered by Dean Kimball in the Jan. 18 issue of your journal, may I offer the following suggestions?

Nothing more timely in the consideration of what should be included in "the content" of the courses given by our educational institutions can be suggested than that our educators dig hard and deep to find a permanent foundation for and build thereupon a constructive course in what I would term a Science of Human Relations. The subject is the very cornerstone among all the educational materials out of which the world's most helpful leaders among men should be technically, morally and spiritually constructed.

As Dean Kimball says, a sound philosophy of what human relations in industry should be has not as yet been formulated, but may it not also be said much, very much, more effort to do so than has been heretofore undertaken may be with correspondingly better understanding? As old as history are the records of man's efforts to find a system of moral direction suitable for all mankind, yet to this day unity of formula seems as far off as before; still such teachers are by their patience and conscientious zeal a great directing force in our civilization.

As engineers many of us are today more than ever impressed by such sayings as "Obligations and duties take precedence over rights and privileges," and again, "His kindliness, wisdom and humanity made him a natural leader." Great harm is too often done by sneering at this moral or ethical basis of any association as the aspiration of overpious and impractical minds, and it is an inspiration for those of us who believe otherwise to read Dean Kimball when he says, "A new industrial day has dawned . . . we are more interested in men than in machines."

These and many similar enunciations of principles

and policies surely are not fully amplified by a general advocacy of the Golden Rule. They are keys and by the synthetic investigation and study of the substance they represent, the first lines are found for a codification of a class of practical knowledge to which our schools and colleges might give more special attention, if not a curriculum status in their courses.

EDWARD F. WHITE,
Middleport, N. Y. Mechanical Engineer.

The Field for University Patents

To the Editor of Chemical & Metallurgical Engineering

SIR:—Dr. Hale's vigorous contribution to the discussion of university patents in your issue of Nov. 16, 1921, is convincing. One cannot disagree, granting his premises. But Dr. Hale has missed the point entirely. I am sure that Mr. Hoskins and Mr. Wiles were not thinking of the location of the eye in a needle as a "basic patent"; nor would it ever have occurred to them that a clutch release could possibly be the object of a university research. Admittedly, these are basic matters for the industries concerned, but from the scientific point of view the only proper results from university researches must be far more basic.

Roentgen's discovery of the X-ray was patentable. That is the sort of thing that universities are giving to the industries with no recompense. Faraday's fundamental work on electric current, Schömbein's discovery of ozone, Daguerre's application of the photo-sensitiveness of silver salts in photography, Millikan's determination of the properties of the electron—these are instances of what pure science has done for industry. And seldom has the scientist or his institution drawn any monetary reward.

Soon a university man will discover how atoms may be broken down into their constituent parts, and will release incalculable energy for human use. This is the sort of work the reward for which should go to the universities, and not to industry, nor primarily to the man who succeeds in it; and if such matters as these are considered instead of the instances which Dr. Hale gives, his arguments are pointless. Such discoveries should not be given outright to industries; neither could they be licensed to any one manufacturer, and no single professor could remain a research man if the administration of the patents were to be in his hands. The only solution which will endow research, reward the inventor, compensate the universities and place the tax where it is due and gladly payable is that suggested by Messrs. Hoskins and Wiles.

Finally, Dr. Hale's chief point is that no matter what the invention, the professor himself should maintain and defend the patent. Messrs. Hoskins and Wiles grant that the inventor has every right to do this, but they realize that the large majority of pure research men are what they are because they have no time for business and could not administer a patent if they would. Hence they suggest that the university provide a repository which will secure all previous benefits and in addition would prevent the scientist from interference by business detail with which he has no concern.

Chicago, Ill. GERALD L. WENDT.

To the Editor of Chemical & Metallurgical Engineering

SIR:—In commenting upon my contribution in your issue of Nov. 16, 1921, Dr. Wendt would have us believe that foundation researches are really patentable. We all agree at the outset that universities should in some way be able to reap rewards for the discoveries of those broader principles, so many of which in the past have fallen to the credit of university investigators. But have these discoveries been patentable in themselves alone? Certainly not. Were Dr. Wendt to apply for a patent on some such general discovery as he has mentioned, he would become painfully cognizant of the necessity of setting forth clearly and pointedly the actual claims in no vague terms, nor could his claims cover the entire field of human endeavor.

If Dr. Wendt will pursue the history of scientific theory, he will find that the possibility of obtaining patents in the name of the leading discoverers was practically reduced to nil in the face of diversified applications so speedily come upon by any number of enthusiasts. When the patent application does not embrace all of the possible claims known at the time, the patent carries little of actual value.

Let us take, for example, a case illustrative of this development from earliest record to final utility. The discovery by Maxwell, the theorist, in 1873, that light is an electric phenomenon could not have been patented, nor also his inference that there are other electromagnetic waves, non-illuminant in effect. Hertz, the research physicist, who in 1886 actually proved the existence of these other electromagnetic waves and described their properties of penetrability as regards solid walls, etc., had little to patent. But Marconi, who in 1896 was able to collect these waves by antennæ and record impulses therein by the flow of current through a coherer, actually hit upon the wireless telegraph, which cannot be construed otherwise than of a basic patentable nature. Now, Hertz deserves greatest praise for his researches, university researches as they were, but everyone knows that he did not have enough to make up a basic patent. Marconi's discoveries, therefore, will ever be regarded as of the basic patent class.

Those discoveries cited by Dr. Wendt were for the most part non-patentable, although they are of general import and certainly give credit to the universities where they were announced. After all, we must not overlook the fact that universities owe much to the industries for their lease on life and certainly these general contributions by universities to science will do much to stimulate further investigations for the good both of the universities and of the industries.

Patents should be obtained upon university researches as well as upon others. The chances for early patents, however, are more likely to fall to industrial research laboratories, where intensive work under high pressure may be instantly inaugurated. My contention has been and still is that the university is not organized to take over the ownership or control of patents and patent rights. In this I feel that university men are thoroughly in agreement, as vouchsafed by over fifty letters recently received by me in commenting upon the contribution of Nov. 16. Not one single case opposing the views therein set forth has come to my attention, save of course these comments of Dr. Wendt.

Let us not forget that university faculties are made up of intelligent men. Were I ever again to be holding a place of honor in a chemical faculty, I certainly would no more consent to have my prerogative as chemist interfered with than I would consent to the university's taking up and handling a case of divorce, assuming thereby that my duties and responsibility to the university as a chemist precluded the possibility of my being able to look after my own affairs.

Midland, Mich. WILLIAM J. HALE.

An Outline of the Uses of Lime*

Chemical Uses: Raw Material in the Manufacturing Industries; Sanitation; Purification of Materials; Food; Catalytic Processes; Utilization of Byproducts; General Utility; Miscellaneous—Construction Uses—Agricultural Uses—Chart Showing Some of the Many Functions and Uses of Lime

By M. E. HOLMES, Ph.D.
Manager, Chemical Department, National Lime Association

THE use of lime in mortar and plaster was, in past ages, its only important use. Coincident with our modern industrial development along technical lines, the lime industry has expanded enormously in the number of its technical uses and thereby has offered a fertile field for the activities of the investigator and writer. The "Uses of Lime" is the subject of a paper read in 1904 by S. V. Peppel[1] before the convention of the National Lime Manufacturers Association. Since then a number of publications have appeared. In 1913 the United States Geological Survey issued a publication on the "Sources, Manufacture and Use of Lime."[2] R. K. Meade[3] in 1914 wrote a paper on the "Composition, Manufacture, Properties and Uses of Lime" and at a later date[4] contributed an article on the "Valuation of Lime for Various Purposes." In 1920 the Bureau of Standards issued a publication[5] under the title "Lime, Its Properties and Uses."

In the present article the author has approached the subject primarily from the point of view of a systematic arrangement in outline form of the uses of lime, grouping the various uses under headings indicating functions performed by the lime. In order to show the unusually large number of functions that lime can perform, we have included not only the well-known uses that represent large tonnage but all the uses of which we have authentic records.

In order to give a proper perspective of the relative importance of the various uses, the latest available data compiled by the United States Geological Survey are rearranged and presented in Table I to show the tonnage distribution of lime by uses. These data are supplied to the Survey by lime manufacturers, who specify the uses for which their lime is sold. The data show that the largest single use of lime is for construction purposes, 1,305,412 tons being reported for 1920. This use is followed by paper mills, with 365,897 tons, agriculture with 351,851 tons, metallurgy with 344,921 tons and refractories with 316,293 tons. At this point there is a large drop to the next important use, which is that for making alkalis, which consumes 104,250 tons. Then follows a gradual decreasing series of figures for the lime consumption in the seventy itemized uses which follow. The item of "unspecified," representing 178,904 tons, accounts for the many other uses for which lime can be and is used. Although it is impracticable to include tonnage figures for the numerous small uses, yet they are important in considering possible future tonnage and in a study of the functional capacity of lime.

In industrial technology it is convenient to divide the uses of lime into three major groups—viz., construction uses, agricultural uses and chemical uses. The construction uses include those involved in building operations, the agricultural uses are limited to the uses on the farm, and the chemical uses include the very large number involved in manufacturing and technical processes. Although the allocation of certain uses is somewhat arbitrary, yet it serves to divide the field in accordance with the duties of the engineer, agronomist and chemist.

The Chemical Uses of Lime

Until recent years the use of lime in chemical engineering processes has been of negligible importance. The rise of the science of chemistry has been attended, however, by disclosures of numerous technical uses for lime which has opened up a new outlet for the industry of such magnitude that it may safely be stated that the chemical uses of lime are now the most numerous and most important in point of tonnage. Calculations from

TABLE I—DISTRIBUTION OF LIME BY USES

	1919	1920
Construction	1,191,434	1,305,412
Paper mills	335,813	365,897
Agriculture	438,632	351,851
Metallurgy	295,622	344,921
Refractories	222,036	316,293
Unspecified	119,770	178,904

data published by the U. S. Geological Survey indicate that lime producers in 1918 sold about 1,900,000 tons for chemical uses, representing roughly 60 per cent of their total. In 1919 this percentage dropped to about 51 per cent, but rose in 1920 to more than 53 per cent. The war undoubtedly had its effect in making the 1918 figure somewhat abnormal, but the indications are that the chemical uses will continue to be the major outlet for our lime production.

The chemical uses of lime may be grouped under nine main heads, which are sanitation, purification of materials, food, catalytic processes, medicine, general utility, byproducts utilization, raw material in the manufacturing industries and miscellaneous.

Raw Material in the Manufacturing Industries

As a raw material in the manufacturing industries, lime functions in processes of saponification, dehydration, hydrolysis, causticization, distillation, high-pressure processes, absorption of gases, coagulation, precipitation, solution, high temperature processes and neutralization of acids.

In high temperature processes lime is used as a fluxing agent in the open-hearth process of steel purification and in the recovery of zinc in the roasting of zinc ore. It finds use as a fluxing agent also in the ceramic and porcelain industries. Lime in the form of very fine quicklime is used as a lubricating agent for dies in drawing steel wire. In electrothermic operations lime is used in the refining of steel, nickel and copper. There is evidence that lime may function as a solute in fused melts whereby alkaline earth metals are produced by electrolysis. Lime functions as an oxidizing agent for carbon under the conditions existing in the manufacture of calcium carbide, cyanamide and silicide and metallic magnesium in the fertilizer and metallurgical industries. Lime is used in fusions such as with silicates to form glass, with alkali hydroxides in making soda-lime and alkali peroxides, with chromite in making chromates, and with clay in the manufacture of aluminum and barium compounds. The manufacture of dead-burned dolomite is possible with the use of lime by a high-temperature calcination process. The manufacture of pottery, decolorizing carbon and silica brick can be accomplished by a baking process in which lime is used with clay, tarry material and kieselguhr, respectively.

In saponification processes, lime functions as a saponification agent for oils in making lubricating greases and various other tar products in the petroleum industry. Organic salts may be saponified with lime in making hyroxides in the dye and organic chemical industry. The action of lime as a saponifying agent for fats, waxes or greases is involved in the cleansing of textiles and also in the manufacture of soap, glue, glycerine, lubricating greases and paints in the animal products industry.

As a dehydrating agent, lime is used in the manufacture of industrial alcohol. It also finds a place in the petroleum industry for the dehydration of petroleum and greases.

Lime is used as a hydrolyzing agent in the manufacture of hydrolyzed glue for use in the prevulcanization treatment of rubber. It can also be used as such in the manufacture of ammonia from aluminum nitride and in the manufacture of pulp cloth from cellulose.

Causticization with lime is involved in the manufacture of alkali hydroxides from sulphates, carbonates and phosphates. Such processes are used extensively in the paper industry for making soda and sulphate pulp, in the inorganic chemical industry for making alkali salts, in the textile industry for mercerizing cloth and for the manufacture of hypochlorites for bleaching purposes, and in the animal products industry for making alkali soaps.

The use of lime as a coagulating agent is extensive in the purification of turbid water for use in making artificial ice and for general municipal purposes. It functions similarly in the settling of ore slimes for the recovery of precious metals in the mining industry, and in the defecation of sugar juices both by the carbonation and sulphitation processes in the cane and beet sugar industry. In the clarification of sorghum juice, for making molasses and in the flocculation of clay in making compounding ingredients for the rubber industry, lime functions as a coagulating agent.

The action of lime as an absorption agent for gases is made use of in the manufacture of acetic acid and acetate of lime in the wood-distillation industry, in the manufacture of bleaching powder and alkali hypochlorites which involve the absorption of chlorine, and also in the manufacture of lime nitrogen salts and nitric acid by the absorption of oxides of nitrogen. The absorption of carbon dioxide by lime is involved in the manufacture of precipitated calcium carbonate, phenol and magnesia insulating material. The absorption of sulphur dioxide, hydrogen sulphide and hydrogen cyanide by lime is involved in the purification of illuminating gases.

In high-pressure processes, lime is used in the direct saponification of fats, in making candles, soap and glycerine. The manufacture of refined oils and calcium soaps from hydrocarbons, the manufacture of sand-lime brick from silica and the manufacture of artificial fuel from peat, tar and coal can be accomplished with the use of lime under pressure. Potash is extracted from greensand and feldspar by aqueous digestion under pressure with lime. This process is also used in the glue industry in the making of siccatives from naphthanates.

Processes of distillation with lime are involved in the manufacture of enriched and purified water gas, ferrocyanides and ammonia. Coal, oil shale and gas works liquors may be distilled with lime for the recovery of ammonia. In the wood-distillation industry, lime is used in the distillation of pyroligneous acid in making methanol, acetone, calcium acetate and acetic acid.

As a precipitating agent, lime is used in the soap industry for making lime soaps which are used as lubricants and waterproofing material. In the paint industry lime is used for precipitating colloidal pigments such as satin white. The sugar industry employs lime for precipitating carbonates, phosphates and sulphites which function as absorption media for impurities in the juice. Cleaning mixtures are made by the precipitation of aluminum compounds with lime. Lime is used also as a precipitating agent for the rare earth oxides in the manufacture of cerium for the gas mantle industry.

The neutralization of acids with lime has an unusually large number of applications in the technical industries. In the paint industry lime is involved in the neutralization of resinous acids for the manufacture of

varnishes and enamels. Certain liquid fuels are stabilized with products made by the neutralization of resinous acids with lime. In the mining industry lime is used for the neutralization of acid ores both in the process of ore flotation and cyaniding and in neutralizing excess leaching acids. Pickling acids in the steel industry are neutralized with lime, as is also residual acid in the manufacture of Keene's cement. The manufacture of patent leather involves a hardening process which may require the neutralization of acids in the dried leather with lime. The insecticide calcium arsenate is made commercially by neutralizing arsenic acid with lime. Lime is used as a neutralizing agent in the manufacture of calcium citrate and citric acid. The neutralization of tar acids with lime is involved in the manufacture of certain kinds of roofing material, bituminous paints, lubricants and sulphonated detergents. Organic acids are commercially neutralized with lime in purifying sugar juices and in making lime soaps, the latter being used in making candles, lubricants, oilcloth and paint. The practice of using lime to neutralize excess acids enters into a large number of industrial processes, of which may be mentioned the making of phenol and sulphonated naphthalene intermediates in the dye industry, synthetic tanning materials in the tanning industry, lithopone in the paint industry, sizes in the paper industry, water-clarifying agents for use in sanitation, cellulose cattle food in the wood byproducts industry, zinc and copper ore leaching in the mining industry, the extraction of nicotine from tobacco, the manufacture of albumen from plants and the manufacture of nitroglycerine and smokeless powder from cellulose.

Sanitation

The uses of lime in sanitation may be grouped under three main heads—viz., the treatment of water supplies, the treatment of sewage and miscellaneous sanitary uses. Treatment of sewage may be either the direct chemical process or the electrolytic-lime process. In the direct chemical process the action of the lime is chiefly that of clarification, the removal of bacteria and possibly the oxidation of organic matter. In the electrolytic-lime process lime effects ionization, electrode passivity, deodorization, clarification and indirectly the removal of bacteria. In the treatment of water supplies lime is used as a precipitating and absorbing agent in deferrization processes and processes of ordinary filtration. It is used also as a precipitating, coagulating and neutralizing agent in water-softening processes. The treatment of the water supplies with lime also includes the neutralization of acid waters and such other miscellaneous processes as the aëration process and the ordinary sedimentation process. The miscellaneous sanitary uses of lime include its use in the disposal of trade waste waters, the manufacture of water-clarifying agents, the destroying of chigres and germs such as in chicken houses, the combating of the fly nuisance by destroying unsanitary breeding places, and the disposal of garbage by processes which provide for the recovery of ammonia.

Purification of Materials

Certain inorganic compounds such as epsom salts, sodium chloride, glaubers salts, borax and ammonium sulphate may be purified by the use of lime. In the soap industry, glycerine water is purified by the use of lime as a precipitating agent. In the purification of illuminating gas, lime functions as an absorbing agent for such materials as sulphur dioxide, hydrogen sulphide and hydrogen cyanide. Caffeine and dye intermediates are examples of organic compounds which may be purified with the use of lime. In the metallurgical industry lime is used as a purifying agent for ferrochromium, the lime functioning as a decarbonating and desilicizing agent. The basic open-hearth process for steel involves the use of lime as a purifying agent. In the petroleum industry lime may be used for the desulphurizing of mineral oils. In the purification of palm oil lime functions as a deodorizing agent. The treatment of coal with lime in the manufacture of coal briquets may be considered a process of purification.

Food

Lime functions as a food for man, plants and animals, affecting growth, health, reproduction and food production. It functions in the growing and manufacture of food, in the manufacture of fertilizers, in preserving food, in making other foods available, in bone and teeth building and in metabolism in general.

Catalytic Processes

Lime enters into certain chemical processes which may be considered catalytic. In the vulcanization of rubber lime serves as a carrier of sulphur. Lime may be used in the contact mass which is used in the hydrogenation of nitrogen in the nitrogen fixation industry. In the reduction of chromium oxide with carbide lime catalytically affects the reaction. In the manufacture of calcium cyanamide from carbide an excess of lime facilitates the reaction. The peroxidation of alkalis is catalyzed with lime.

Utilization of Byproducts

The metallurgical industry makes use of lime as a fluxing agent in the recovery of scrap iron. This industry also makes use of lime in the disposal of byproduct slag in making building brick. In the electrolytic alkali industry byproduct chlorine is recovered by absorption with lime, forming bleaching powder. In the lumber industry byproduct sawdust is saccharified with acids in making cattle feed and lime is used in the neutralization of the excess acid. In the mining industry waste ore liquors may be treated with lime for the recovery of hydrogen cyanide. Potash feldspar quarry waste may be used with lime in the manufacture of fertilizers. In the coal-mining industry, colliery waste is admixed with lime and made into coal briquets. In the manufacture of potash from greensand the byproduct silicates are utilized with lime in making building brick. Brick may also be made by the use of lime and coal ashes or blast-furnace slag. In the manufacture of illuminating gas the waste gas-purifying material may be treated with lime in the recovery of ferrocyanide. The sugar industry makes use of lime in the recovery of ammonia from beet residue, in the manufacture of cement from press cake and in the manufacture of calcium saccharate, alcohol and fertilizers from waste molasses. Waste tannery liquor is utilized with lime in making fertilizers. Corncobs are utilized in the manufacture of paper which involves the use of lime for neutralizing excess acids. In the paper industry the use of lime is involved in the recovery of acetone, methanol, ethyl alcohol and decolorizing carbon from waste sulphite liquor and sodium acetate from waste soda pulp liquor.

The general utility of lime extends to the home,

laboratory, hospital, factory and mine. In the mine, lime is used for the neutralization of acid mine waters, for the neutralization of ores in flotation processes, in fluxing operations and for the whitening of mine walls. In the factory, lime is used as a raw manufacturing material, as a cold water paint and for disinfecting and general sanitary purposes. In the laboratory, lime finds use in a large number of ways, including its use as a chemical reagent, as a dehydrating agent and as a gas-absorbing agent. Around the home, lime is used in whitewash and cold-water paints, it is used on the field, garden and lawn, for preserving eggs, for outhouse sanitation, as a fuel ingredient and as a food and medicine. In the hospital, lime finds use for general sanitary purposes.

Miscellaneous

Lime acts as a scouring agent in several industries, including the scouring of rags in the paper industry, the scouring of textiles in the dyeing industry and of metals in electroplating processes. Lime is used in the cooking of certain materials such as animal matter in the manufacture of glue and of vegetable matter in the manufacture of paper and dyes. The briquetting of iron ore in the smelting industry involves the use of lime, as does also the briquetting of such vegetable matter as lignite in making fuel. Lime is used as a cleansing agent for wooden containers such as cider and oil barrels, for metals of various kinds as a preliminary to the polishing process and it serves as a cleanser for unsanitary containers such as garbage cans. In electric welding, lime serves as a weld regulator and coating for the electrodes. In illumination, lime is used directly in the limelight and as a gas-purifying material in the gas industry. Lime serves to retard rusting of metals such as iron under certain conditions. In ore flotation pine oil may be rectified with lime. Lime is sometimes used in the dye industry for mordanting, particularly in logwood and turkey red dyeing. The milling industry makes use of lime to remove smut spores and thereby improve the grade of the grain.

The miscellaneous uses of lime include the fabrication of a large number of products, some of the more important of which are phenolic aldehyde, photosensitizers, calcimine, crucibles, 85 per cent magnesia, chlorpicrin, basic alkaline earth compounds, alkaline earth oxychlorides, gas mantles, hydraulic cement, artificial stone, fibrous composition, camphor, cacao, pharmaceuticals, calcium light pencils, phosphorescent mixtures, tungsten and molybdenum compounds, buffing and polishing compounds, oxidized turpentine, trichlorethylene, magnesium flashlight powder, soda-lime, calcium and magnesium salts, antiseptics, quick drying varnishes, and carbonizers for metals.

Construction Uses

The lime industry had its birth in its construction uses. The most ancient record of the use of lime is as a mortar and plaster. The development of the art of lime manufacture and of its use in construction was well on its way before our technical manufacturing industries began to develop. As a result of this time element we find the art of the construction uses of lime in a relatively advanced state compared with the other uses. Although the construction uses of lime are not numerous, yet the tonnage is very important. In 1918, about 28½ per cent of the lime manufacturers' tonnage was for construction uses. In recent years this percentage has increased somewhat. With the improvements in the quality of material, the standardization of the product and the development of new construction materials, this use of lime bids fair to thrive, especially in the next few years.

Mortar

The use of lime in mortar is the most impotrant one in the construction field. It is used in brick mortar, tile mortar and stone mortar, both in the form of gaged and straight lime mortar. In these materials, lime performs functions which have been explained in various ways. Lime serves as a bonding agent by taking on a stone-like set through the process of recarbonation and thereby, with the intermixed sand, not only binds the main elements of the structure but also fills the larger voids. Limes of various kinds perform varying degress of plasticizing action in the wet mortar, affecting the ease with which it is spread. Characteristic also of lime mortar is a certain resiliency or elasticity which has been expressed by attributing to lime the function of a toughening agent.

Plaster

Lime is used in the scratch coat, brown coat and finish coat of plaster. These may either be straight lime or gaged plaster in which lime serves as a bonding agent, whitening agent, plasticizing agent and as a sound-deadening agent.

Concrete

Lime is used in both cement and asphaltic concrete. In asphaltic concrete lime serves as a hardening agent, filling agent and cooling agent. In cement concrete, lime serves as a hydrating agent, plasticizing agent, strengthening agent, water-tightening agent and whitening agent, and as a physical stabilizing agent to prevent segregation.

Stucco

There are three kinds of stucco—viz., straight lime and gaged stucco and sorrel cement. In the first two, lime serves as a bonding agent, plasticizing agent, toughening agent and water-tightening agent. In sorrel cement the action of lime is primarily chemical instead of physical.

Sand-Lime Brick

The function of lime in the manufacture of sand-lime brick is much the same as that of the other construction uses—viz., bonding (both physical and chemical), strengthening, whitening, hydration and neutralization.

Cold-Water Paints

Cold-water paints are conveniently divided into whitewash and complex paints. In these products lime serves as a protecting agent against wind and weather, as a pigment, as a hardening agent, as a cementing agent and as a rust-preventing agent. In certain of the complex paints it enters into chemical reactions such as the saponification of oils, the precipitation of phosphates, fluorides, etc., and in the solution of siccatives.

Agricultural Uses

The agricultural uses of lime may be divided into two main divisions—viz., crop production and livestock production. In crop production, lime is made use of both in connection with plant growth and with crop protection. In livestock production lime is made use

of in connection with animal growth, animal protection and animal products.

Crop Production

Plant growth is affected by lime through its use on the soil. This use extends to field, truck and orchard crops, in connection with which it performs a number of functions. It corrects active free acid and thereby a chain of effects results, including the promotion of organic decay, nitrogen fixation and nitrification by organisms. It serves as a granulating agent by flocculation of colloids, both inorganic and organic, thereby improving the soil tilth with the long chain of physical benefits that result from such a change. It serves as a detoxicating agent by its action in precipitating aluminum and iron salts. Inside of the plant it serves as a direct plant food and as a physical regulating agent by its effect on food transfer, cell rigidity and protoplasm activity.

Crop protection with the use of lime extends to both the growing crop and the garnered crop. The use of lime in the protection of garnered crops involves its action as a disinfectant carrier against fungi and as an insect-repelling agent against weevil.

The protection of growing crops by lime enters into a number of ramifications in which it performs four important and distinct functions. Lime serves as an adhesive agent in sprays, such as paris green and the arsenates for use against chewing insects. Lime is used directly as a regulating agent against such diseases as corn root rot and vegetable clubfoot. Lime performs the function of an inhibiting agent against excess action of such sprays, washes and dusts, as whitewash, lime mixtures and bordeaux lime-sulphur, which are used in preventing foliage burning, seedling burning and early budding.

The most important use of lime, however, in crop protection is as a compounding ingredient for insecticides, fungicides and poisons such as lime sulphur, bordeaux mixture and calcium arsenate respectively. These materials are used in combating the San José scale, oystershell scale, scurfy scale, scab, black-knot, bitter-root, peach scale, brown rot, leaf curl, flea-beetle, potato-beetle and cotton-boll weevil.

Livestock Production

Animal growth is affected by lime through its use in feed both leguminous food and mineral mixtures wherein lime functions as an agency for bone building, conditioning, metabolism and teeth building. It affects animal protection both as a medical agent and as a disease-resisting agent against tuberculosis and abortion. The animal products that are affected by the use of lime are dairy products and eggs. Lime is a shell-forming agent and thereby affects the production of eggs. In the form of lime water it is a preservative for eggs. The manufacture of butter employs the use of lime as a milk food, and as a neutralizing agent for sour cream. It is also thought to function as a preserving agent for flavor and composition.

Closure

This review of the functions that lime performs in its numerous uses indicates that it is a most remarkable chemical. It is doubtful if there is any other chemical that is used in such a large number of diverse processes. In the construction uses of lime it performs at least seventeen different functions. In its agricultural uses it performs at least nineteen different functions. In its chemical uses it functions in a very much larger number of ways. Not only is lime as a chemical characterized by the large number of functions it performs but, what is more important, by the exceedingly diverse nature of its functional capacity. It is used as an oxidizing agent and as a reduction agent, it is used as a dissolving agent and a precipitating agent, it is used for the absorption of gases and for the expulsion of gases, in one form it acts as a dehydrating agent and in another form as a hydrolizing agent. Surely it is one of the most versatile of chemicals.

The nation is fortunately provided with an adequate supply of the raw materials for lime manufacture and with a lime industry adequately prepared to supply all demands with a high-grade standardized product. The industry can also produce various kinds of limes of widely varying chemical and physical properties. Lime is distinguished therefore not only by its versatility but by its cheapness, general availability and by its adaptability to the special requirements of its various uses.

What the industry needs is a larger tonnage outlet in the way of new and larger uses. It is the chemical engineer who can supply that tonnage. Fundamental research is needed on lime, its properties and uses under such headings as lime as a coagulating agent, lime as a dehydrating agent, etc. The field is a fertile one. The great potentiality of lime as a national asset has not been adequately realized.

Extent of Potash Deposits in Oil Fields

The discovery of potash in samples of salts recently received by the United States Geological Survey from new wells bored for oil at two additional localities in western Texas extends the area in which small amounts of potash salts are known to occur about 30 miles north and 50 miles east of the area of previous discoveries.

Starting from the Means well, which is close to the New Mexico-Texas line, in Loving County, about 20 miles west of the southeast corner of New Mexico, the boundary of the area in which potash in notable richness has been found in the red beds runs southward for 30 miles to well No. 1, or the river well of the Pitts Oil Co., about 8 miles east of Barstow, thence east by northeast 130 miles to the McDowell well in northern Glasscock County, and thence north by northwest 50 miles to the Burns well, in Dawson County, from which it returns in a west by southwest direction to the starting point. Indications have also been found in the Panhandle.

As all these wells were drilled for oil and the easily soluble salts were of secondary consequence to the drillers, the samples recently forwarded, like the samples previously received from this region and analyzed, were accompanied by scant data relative to the water in the wells, the length of time it had been in contact with the salts, the condition of casing, etc. So many unknown conditions must therefore be taken into consideration that it is impossible to say whether the potash-rich salts already analyzed represent beds several feet or only a few inches thick. Core-drilling will have to be done in order to answer these questions. However, those who are drilling for oil in this region are showing more interest in the possibility that potash may be found in their wells and are preserving better samples and furnishing fuller data.

Results Achieved by the Corrosion Committee British Institute of Metals

Failure of Brass Condenser Tubes in Marine Service Is Caused by Lodgment of Solids, Harmless in Themselves, but Which Trap Corrosive Substances Formed During the Inevitable Process of Slow General Thinning

By ERNEST E. THUM

IT IS rather difficult if not presumptuous to attempt to summarize the labors of the Corrosion Committee in a small space, since its investigations have been continuously under way for 10 years and its published reports cover 650 pages of the Institute's journal. The task is within reason only because but brief mention need be made of the early experiments, since they were much like groping in the dark. Current beliefs had first to be tested and discarded. Then a tremendous number of the ordinary "loss of weight" determinations were made before it became absolutely certain that this method was leading nowhere. Furthermore, some of the ideas strongly supported in the earlier reports have been greatly modified or even discredited by more precise work undertaken in later years.

Finally a carefully planned series of investigations disclosing the fundamental mechanism of the corrosion of brass was performed, and the information thus disclosed was used in interpreting the performance of new tubes in condensers operating under known circumstances.

In passing, it would be well to remark that the published results have been confined to that particular problem—that is, the corrosion of condenser tubes[1] in water. The searcher for information on corrosion should therefore consider the limitations of these publications, and translate their results to other situations with great circumspection.

In view of these circumstances, attention can be kept almost wholly upon the more recent reports. These confine themselves to the action of 70:30 brass condenser tubes in sea water and fresh water.

Organization of Research Activities

But first a word may be said about the organization. The founders of the Institute of Metals believed that its prime function would be to combine scientists, manufacturers and users in a joint quest for the reason why mysterious difficulties in the manufacture and use of alloys suddenly crop up, give no end of trouble and then as suddenly and mysteriously vanish. In view of the fact that many condenser tubes were apparently failing through corrosion after very short life, a committee was appointed and first met in May, 1910, under the chairmanship of Sir Gerard Muntz, to formulate ways and means to investigate that situation.

Mr. Bengough, then lecturer in metallurgy in the University of Liverpool, undertook to prepare a summary of the literature dealing with the corrosion of nonferrous alloys. He found that very few factors of the problem had been satisfactorily explained, and the first of his five reports—presented in September, 1911—was therefore confined to an exposition of the electrolytic theory of corrosion and a consideration of the possible causes of potential difference on the surface of an apparently uniform piece of metal.

Meanwhile the committee appealed for funds. Annual donations were made by the Institute, the Brass and Copper Tube Association, Lloyd's Register and various manufacturers, but with few exceptions the users of tubes refused to contribute on the ground that it was none of their affair, but that of the tube maker and the condenser manufacturer! An experimental plant, imitating carefully the details of a surface condenser on shipboard, was constructed at Liverpool University at a cost of about $1,000, but this was closed down after 9 months' running for the lack of operating funds. A figure between $3,000 and $4,000 financed the research up to 1917. Its investigations were then moved to London, enlarged under governmental auspices, and several problems connected with war work were submitted. The government donated £1,000 per year, and various manufacturers' associations more than duplicated that figure. With ampler funds, and the co-operation of many governmental and educational agencies, work has progressed along many lines, only a few of which can be mentioned here—indeed some of them are only indicated in the various reports.

Circumstances Surrounding Troublesome Condensers

One of the first requests made by the Corrosion Committee was for submission of defective tubes for examination, together with data on the service conditions. As a result many tubes were collected, but it was impossible to get more than a general idea of the problem in this manner, since the users could not define the surrounding circumstances with much clearness. To diagnose troubles, the consultant should know about the supply of cooling water—its chemical and mechanical analysis at seasonal variations and whether or not it is recirculated. He must know the metal comprising water mains, tubes and water ends; details of any attempted scheme of protection; the joint construction; whether tubes are often choked with sediment; the speed of cooling water and its temperature at outlet. Much information about the location of the trouble is needed: how soon did it occur; is it confined to a certain condition, to a few tubes in a certain part of one condenser, or to a localized part of a few tubes; is the steam properly deflected to all parts of the condenser; are the accessory parts also corroding? About the only way in which an investigator can be sure of getting this in-

[1] The following metals were used: Copper, zinc, aluminum, 70:30 brass, 61:39 brass (Muntz metal), 78:28:2 Pb special brass (Muntz "Nergandin"), 70:29:1 Sn Admiralty brass, 96:4 phosphor bronze and 92:8 copper-aluminum.

formation is to go to the plant himself, and this practice has lately been followed by the Corrosion Committee. In some cases fresh tubes have been placed and are under periodic inspection. At one power station an experimental condenser is in constant operation, and the Royal Navy has fitted half of a twin condenser with specially prepared tubes, under the committee's directions. From these commercial tests much reliable information will be forthcoming.

Study of Defective Tubes

Nearly all the brass tubes first submitted for examination had rapidly failed in service by corrosion at a few spots and in a manner which left behind more or less metallic copper, free of zinc. Depending upon past performance, a normal life to 50 per cent thinning was variously thought of as from 4 to 25 years, but it was common report that one shipment may show wide variations in durability (1 to 3). One 70:30 tube, taken from a trawler after 20 years' service, showed no trace of this apparent dezincification, and had lost not more than 0.05 mm. thickness. Such observations confirmed the general impression that localized attack was the culprit. Consequently it was essential to discover and remove the causes of pitting. The complexity of these causes may be inferred from the fact that if these same defective tubes were split, ground, polished and suspended in still sea water, they showed no localized dezincification. In 9 months the thickness had been uniformly reduced about 0.04 mm. and the pieces were covered by a film of dark brown copper oxide.

Despite the fact that concentrated attack was so early judged to be the damaging cause rather than general thinning (which indeed is always to be expected), it was not recognized until after the third report (1917) that repeated weighings of metallic samples would not answer the problem. Even when studying general thinning by non-selective attack, the actual amount of corrosion should be measured by the amount of metal disintegrated, which includes the metal passing into solution and remaining there, being redeposited as such, or being precipitated as an insoluble salt, the metal remaining on the sample in the form of oxide, and the metal lost by exfoliation. At present the total metal disintegrated is impossible to determine. A loss-of-weight experiment merely estimates the underlying metal plus the overlying scale. Successive weighings give no measure of the maximum penetration, the result becomes more inaccurate with time, and is subject to a great many uncertain factors. For instance, a table in the third report gives twelve duplicate experiments under conditions where only slow general corrosion at the rate of 0.05 mg. per sq.cm. per day was observed, but the average difference between pairs (supposedly identical) amounted to 19 per cent of the loss in weight. Determination of the minute amount of metal in the solutions and loose precipitate is difficult, and when used in calculations indicates only the weight of oxygen or other non-metallic products in the adherent scale. And finally the scale cannot be reduced or removed without affecting and destroying some of the underlying metal.

Those who still rely upon this kind of data may find a mine of information in the thousands of experiments on various kinds of condenser tubes published in the second and third reports.

Depth of pit is actually the most important consideration. Lacking some method of determining this, careful microscopic examination of the surface is the best method now known of attacking the problem of localized corrosion of 70:30 brass.

Protective Layers

Comparison of the 20-year old tube from the trawler with others which failed in less than that many months showed a very pronounced difference in the adhering scale. Early experiments also showed that the nature of the film first to form on the bright sample after immersion in sea water of various temperatures, aëration and dilution had a determining influence on the subsequent history of the experiment. In some cases this film will become darker with time, finally reaching a thickness of about 0.04 mm.; it is "glazed" in appearance and very tenacious. It does not seem to be wholly impervious to the corroding solution, since the metal in solution plus that in a loose precipitate gradually increases in amount. Yet it remains continuous and intact, and experiments extending nearly a year show the expected life of a tube with such a covering would be 15 to 20 years before 50 per cent thinning.

On the other hand, samples of metal of almost exactly the same composition, having no determinable differences in physical constitution or surface condition, when immersed in a companion beaker will first develop a film which cannot be distinguished from the other, but after a short lapse of time specks of adherent colored salt form here and there, grow and apparently perforate the original glaze. If removed, a red coppery area is seen. Localized corrosion has begun, and the tube is on the rapid road to failure. No reason can yet be given for these experimental results. Strangely enough, further work has shown that if a certain tube develops the resistant coating, all the tubes of that batch will also do so. Another batch, indistinguishable from the other, from the same reliable maker, will all develop the corrosive salt deposits!

Furthermore, when making brass cathodic to iron by an impressed current, under conditions similar to those obtaining in the electrolytic system of protection, the alloy remains bright after immersion in sea water, and at the end of, say, 3 weeks is found to have been covered with a thin, pinkish, translucent layer of calcium carbonate, quite hard, uniform and adherent. This layer does not entirely prevent corrosion, neither does the continual cathodic condition of the metal, for a thin layer of copper oxide gradually forms between the carbonate film and the metal, and general corrosion ensues—but at a very slow rate.

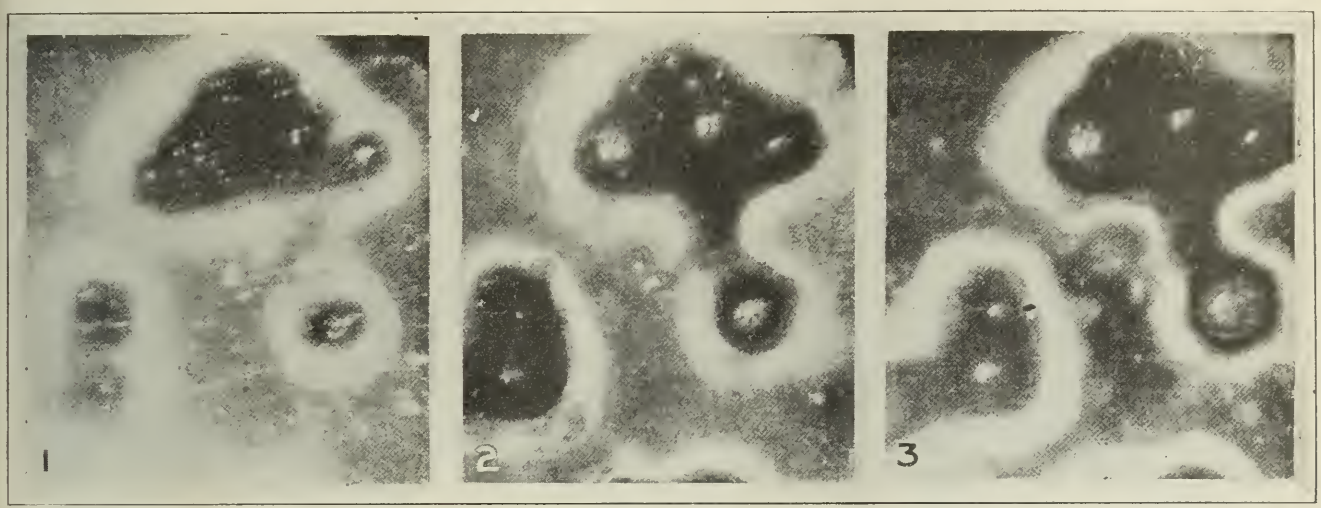
The Surface of a Tube

Such findings impressed Mr. Bengough and his associates with the fact that the surface layer—possessed by the original metal or built up upon it after immersion—had a determining influence on corrosion resistance to which nearly all other circumstances were secondary. Consequently great efforts have been made to determine the nature of these films.

A supporter of Beilby's amorphous theory would have no hesitation in accepting a statement that the surface of a tube, as received from the maker, is materially different from the underlying metal. For one thing, it is badly distorted from the cold work of the last draw. Previous annealings have doubtless volatilized some of the zinc and oxidized some of the copper. The actual surface should then comprise a thin sheath containing an unusual amount of amorphous metal, low in zinc and laminated with copper oxide.

A layer varying in thickness from 0.005 to 0.02 mm. can actually be removed from a section of 70:30 condenser tube. It flakes off, beginning at the edges, after a couple of weeks in 1 per cent NH_4Cl solution, and may often be recovered in sizable, coherent scales. Under the microscope it appears structureless; the outside surface still retains the draw lines, showing that the layer itself has resisted corrosion almost completely. The inside surface is more or less "pebbly." Analysis shows it to contain 73 per cent copper.

The underlying metal has been deeply attacked and its crystalline structure developed, thus exhibiting its essential difference from the resisting surface layer. Strangely enough, the reagent seems to attack the metal most readily along intercrystalline and intertwining plane material. It may be that the metal of the surface layer is different in some way from that which cements crystals and crystalline fragments. Or it may be that rapid corrosion on internal surfaces may be similar to that caused by mercurous nitrate in strained brass which eventually would fail by season cracking. These questions, and the differences between the surfaces which build up protective layers and those which do not, are problems yet to be solved.



FIGS. 1 TO 3—CAST ZINC SUSPENDED HORIZONTALLY IN DISTILLED WATER. OBLIQUE ILLUMINATION. × 70
Fig. 1—15 min. after immersion. Fig. 2—85 min. after immersion. Fig. 3—4 hours after immersion.

Corrosion of Zinc in Distilled Water

Zinc and copper were both closely observed, during the early stages of corrosion, hoping thereby to throw light upon the main problem—the rapid localized corrosion of 70:30 brass. A piece of smooth, clean, cast zinc (99.97 per cent pure) was immersed horizontally in distilled water[2] and observed under oblique illumination at 75 diameters. Figs. 1 to 6 from the fourth report are selected from a series given as typical.

Immediately upon immersion the surface showed numbers of small bright spots (minute holes) and scratches from the 00 emery paper used for final polish. Within 5 minutes curves ridges of bluish white material began to appear, which in 15 minutes had joined to form halos about portions of bare metal, bright and clear. (Fig. 1.) Outside the halos the metal gradually became covered with this gelatinous whitish material, shortly it became thick enough to obscure the scratches—however, there is little action in these regions, for when the precipitate is removed it is found that the scratches are not obliterated. It is an oxide or hydroxide of zinc, free of CO_2, and when dry exposes a somewhat nodular structure.

However, vigorous action proceeds inside the halos. Within 30 minutes definite pits seem to be forming as bright spots at the center of curvature of these ridges of zinc hydroxide. A definite convection is observed, upward and outward from the pits, building up the walls of the halo, toppling them over at times, whereupon the underlying corrosion will later be found to have advanced correspondingly. (Compare Figs. 2 and 6.) After 2 hours a secondary and inner halo forms around prominent pits. (Fig. 3.) This halo turns out to be an area of roughened surface, slowly and gradually spreading; it often is separated from the pit by a ring of unattacked metal; roughened surfaces sometimes occur in successive rings. (Fig. 4.) Despite appearances the pits are filled by a transparent gelatinous hydrated oxide. This is a fact of considerable importance, since it is often assumed that no corrosion exists in the absence of *visible* rust.

In about 4 hours feathery white crystals containing CO_2 appear at the outer surface and edges of the halos. Gradually all these details become obscured by the ever-increasing mass of corrosion products (Fig. 5), but a clear—sometimes tortuous—passage is always maintained from the pit to the outside solution. If after 72 hours the sheet is cleaned by dilute acetic acid, the corrosion is seen to have been almost entirely confined within the original hydroxide walls. (Fig. 6.)

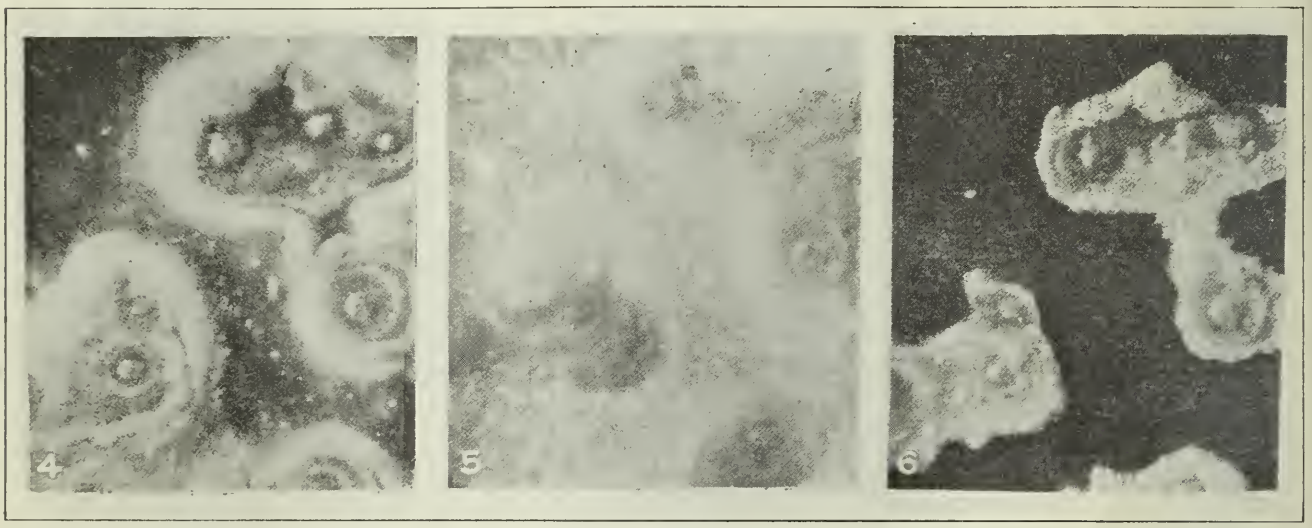
Contrary to the usual assumption that the location of the pits can be correlated with some definite property of the surface, Captain Bengough is positive in his statement that neither the original holes, artificial holes or scratches can be associated with these halos. That their location is dependent on factors external to the metal is demonstrated by Figs. 7, 8 and 9, which show the same piece of cast zinc after suspension in distilled water, lengthwise, sidewise and after having been immersed and spun horizontally. Corroded streaks of this sort have been observed microscopically during formation, and are caused by toppling halos of zinc hydrate moved in definite directions by gravity or water currents. Thus the arrangement of pits is determined mainly by the *distribution of the products* of earliest corrosion.

It has also often been stated that the corrosion of

[2]Distilled water was shown in the third report to attack zinc four times as fast as sea water.

metal by water is similar to acid attack—i.e., consists of hydrogen replacement. However, no evolution of hydrogen can be seen (under 400 magnifications) in distilled water, although 1:5000 acetic acid, which removes zinc at the same rate, produces very small hydrogen bubbles. In acids which pit, hydrogen appears to be evolved in the pit itself, and not at some distant cathode. Experiments with gas-free water seem to show that oxygen is an essential, and CO_2 is an accelerator of corrosion. It is inferred that oxygen does not act as a depolarizer of electrochemical action, since there is no water-line attack when zinc is partially immersed in distilled water, and from the fact that the addition of a powerful depolarizer like potassium bichromate actually retards corrosion of zinc.

Weighing all the evidence, the authors postulate that before immersion the zinc has had opportunity of acquiring a layer of oxide or basic carbonate, and its further history depends upon the action of the corroding solution on this coating. Dilute acids dissolve it, and zinc then may replace some hydrogen from the acid. Water with CO_2 in solution does dissolve the coating slowly, taking Zn into solution as bicarbonate and penetrating the surface layer at some points. Here an unknown oxide (peroxide?) is formed by the oxygen in solution reacting with the bare metal. This is highly transparent, gelatinous, non-adherent, and is an accelerator of corrosion. It is carried outward, is converted to ordinary hydroxide or basic carbonate slowly, in which condition it becomes more opaque, insoluble and protective to the metal upon which it lodges.



FIGS. 4 TO 6—CAST ZINC SUSPENDED HORIZONTALLY IN DISTILLED WATER. OBLIQUE ILLUMINATION. × 70
Fig. 4—24 hr. after immersion. Fig. 5—72 hr. after immersion. Fig. 6—After cleaning with acetic acid.

Oxidation of Copper in Water

Action of distilled water on electrolytic copper is much slower than on zinc, but many experiments led Dr. Bengough and his collaborators to the conclusion that here again the variations to be observed in corrosion experiments depend upon the differences in the resisting power of the first-acquired tarnish film rather than differences in the underlying metallic structure. Bright polished copper, as well as specimens annealed and cooled in hydrogen and immersed without coming in contact with air, remain bright for 2 months and lose weight at an almost vanishing rate, but when removed and dried show the acquisition of the same thin, adherent and uniform layer of tarnish which is acquired by specimens not specially prepared. Such a coating can apparently be formed only by direct oxidation of the copper.

After 3 months' immersion a clean piece of electrolytic copper will retain portions of its surface-tarnish intact, where the underlying metal has not corroded. But this gelatinous tarnish is soluble to a very slight extent in distilled water, and is converted slowly to a darker porous mass, overlying shallow pits where "autocorrosion" has started. The whole mass of oxide in this vicinity becomes very loose, and even flakes off. Later some of the oxide or metallic copper in solution is changed in nature and is precipitated as crystalline Cu_2O, which persists almost indefinitely. Eventually all oxides tend to blacken. If the loose secondary oxide is dissolved in HCl it is found to analyze 80 per cent Cu, and when this factor and determinations of copper in solution is applied to loss-of-weight experiments, remarkably consistent rates of corrosion are shown up to 160 days, as follows:

Cast copper in stagnant distilled water loses 1.7 mg. per sq.dm. per day.
Copper foil in stagnant distilled water loses 1.7 mg. per sq.dm. per day.
Arsenical copper in running distilled water loses 1.7 mg. per sq.dm. per day.
Cast copper in running distilled water loses 3.3 mg. per sq.dm. per day.

One piece of evidence that the oxidized film has determining influences lies in the fact that immersion in 1 per cent NH_4Cl (which has forty times the solubility for cuprous oxide as has distilled water, and also dissolves oxygen readily) causes rapid general corrosion of electrolytic copper without a trace of pitting. No tarnish film is formed, or it is dissolved as rapidly as formed, and the metal remains bright. Electrolytic action at anodic areas is an extremely rare occurrence. Indeed, the phenomena described above occur, but at a slower rate, when the copper is maintained cathodic by an applied e.m.f.

Stagnant and aërated sea water corrode copper in the same way, differing only in degree. The metal is first covered by a continuous film of cuprous oxide; in about 7 days a crystallized salt forms on the surface and then flakes off, often carrying the underlying

oxide with it. Bare metal thus exposed is apparently different from a polished surface, for it is a seat of rapid corrosion rather than a generator of a resistant membrane.

General Thinning of Brass

If a smooth piece of cast 70:30 brass be immersed in cold sea water, both the copper and zinc are oxidized immediately to form a superficial membranous tarnish. Constituents of this layer react slowly with the solution, forming basic carbonates and chlorides, mostly detached. This second reaction is slow, consequently the oxide layer gradually increases in thickness; it is also preferential, so that the oxide layers become rich in copper. However, the coating overlies yellow brass, so the corrosion is general, and eventual failure would be by general thinning, but very far distant in normal sea water.

Rapid thinning is essentially a fresh-water phenomenon, and is associated with the presence, at some time, of dilute solutions of free acid or alkalis. Thus, the

FIGS. 7 TO 9. CAST ZINC IMMERSED 24 HR. IN DISTILLED WATER. HALF SIZE

Fig. 7—Suspended lengthwise. Fig. 8—Suspended sidewise Fig. 9—Rotated horizontally

fifth report recounts experiments on twelve different kinds of tubes immersed in 30 parts HCl per million, renewed daily. Action started from the cut edges and at pin spots, undercutting the protective surface layers and peeling them off in large flakes by the formation of oxysalts *in situ,* laying the bare metal open to direct acid attack. All surface protection is thus rapidly lost, the brassy, crystalline surface appears slightly roughened and is covered with a thin reddish layer of copper and copper oxides. From 2 to 4 per cent of thickness may be lost in 6 weeks immersion in this weak acid, an amount which tubes in favorable sea water service may exhibit after 18 years.

Temporary acidity is only slightly less dangerous. A little acid entering the condenser would perforate the protective scale and surface layer at some point where it is thin or interrupted by slag or a "draw," and then, even if the water was neutral thereafter, the resulting depression would provide a lodgment for oxides, salt or other bodies, known to cause accelerated "deposit" attack—of which more later. It is therefore most important to prevent the entrance of acid by continually maintaining the circulating water alkaline with lime water or sodium carbonate solution to the extent of 10 to 15 parts per million.

Attack by Deposits

We have thus led up to a consideration of the principal cause of deterioration in brass condenser tubes: regional corrosion or pinhole pitting caused by accelerated attack underneath adhering deposits.

It has already been noted that brass condenser tubes of commerce possess a copper-rich surface layer, containing more or less oxide. Also that the first action of corrosion is upon a thin oxidized coating rather than upon the underlying metal. Now, if a piece of smooth copper be immersed in chloride solutions, the oxidized surface gradually changes into an almost insoluble cuprous chloride (CuCl), which ordinarily is swept away by gravity or by water currents, but which may adhere to the surface. In the latter case the cuprous chloride becomes oxidized according to the reaction

$$4CuCl + O \rightarrow Cu_2O + 2CuCl_2$$

into cuprite crystals and the very corrosive, soluble cupric chloride. Sometimes, instead of crystalline cuprite, colloidal green salt is formed,[3] which is very adherent and prevents the outward diffusion of cupric chloride. It is easily proved that cupric chloride is very corrosive to copper in a wide variety of concentrations, according to the reaction

$$Cu + CuCl_2 \rightarrow 2CuCl$$

and the end product is where we started from. Therefore these reactions recur in a cycle at spots underneath gelatinous salts permeable to oxygen in solution.

Brass in chloride solutions acts similarly. As noted before, the first attack gives a layer of copper oxide, plus a little zinc oxide, the zinc mainly going into solution as $ZnCl_2$. Reactions on the copper oxide then proceed as outlined just above; if the insoluble chlorides adhere to the surface cupric chloride is formed. Cupric chloride attacks zinc as well as copper,

$$CuCl_2 + Zn \rightarrow ZnCl_2 + Cu$$

with the formation of soluble zinc chloride and the deposition of crystalline or powdery copper.

Some zinc oxide is formed in the original membranous coating. It is slowly dissolved in salt solutions, and in the presence of carbonates may be precipitated as a white basic chloride or a green double salt with copper. If these materials adhere to the metal as crystalline plates they are distinctly protective; if they are flocculent they cause pitting by trapping the corrosive cupric chloride.

This is a general statement of the mechanism of all severe corrosion of brass in sea water. Pitting is seen to be due to a product of corrosion held in place by a deposit of some sort; the location of the pits is a matter of chance. Coke particles, clinkers, sand from various sources, pieces of glass, and even massive flakes of ferric hydrate or a piece of string all act in the same way. Electrochemical action is distinctly secondary; wherever these foreign matters find lodgment they form eddies in which cuprous chloride can lodge. Later, thick deposits of bright red cuprous oxide, ruby cuprite and greenish and white basic salts accumulate. These break away on reaching a certain size, often taking with them a tiny slab of underlying metal, exposing the crystalline structure underneath in a crater which speedily fills with corrosive substances.

Furthermore, water-line attack is only a special case of "deposit" attack, doubly dangerous since the deposit forms under especially favorable conditions. Contrary to common report, it occurs as severe irregular local action up to 2 cm. *above* the water line, where the above described salts have crystallized. These corroded spots are always connected with the water by a continuous moist band acting like a capillary tube.

[3]Hydrated basic cupric chloride, corresponding to atacamite, $CuCl_2.3CuO.4H_2O$. Ordinarily the sea water contains some CO_2 or bicarbonates, which enter atacamite, turning its color somewhat blue. This circumstance slows down the subsequent reaction, but does not change its nature.

Apparent Dezincification

A great deal of space in the fifth report is given to evidence that the so-called dezincification commonly observed in corroded tubes is never caused by preferential solution of the zinc, but always to redeposition of copper from cupric chloride solution by metallic zinc. Thus: if a piece of brass is made cathodic to iron in normal $CuCl_2$ solution for 14 days, it will be found on microscopic examination that the original metal has been reduced about 10 per cent, but the total thickness of the cathode has been increased 30 per cent. This difference is soft, coherent, ductile copper; whatever crystals are observed are of a different nature than the brass structure. The bulk of this copper must have been redeposited, but the outermost portions appear to be identical with the innermost, where any dezincification surely must have been proceeding, and where the residual copper should be powdery or pseudomorphic after brass crystals. Lacking any observable difference in appearance, and since the outer portion must have been deposited, the inner portion is also assumed to have been likewise deposited.

Prevention of Corrosion

Since rapid corrosion of brass in sea water is due to some phase of "deposit" attack, the obvious remedy is to prevent the adherence of deposits or the accumulation of sediments. This seems to be the principal virtue of the so-called electrolytic methods of protection—as mentioned earlier in this review, the current builds up and maintains a layer of $CaCO_3$ which is so smooth as to prevent lodgment effectually.[4] All foreign matter could evidently be kept out of the condenser water by adequate screening, or if it is suspected that solids have entered, the condenser should be thoroughly cleaned at the first opportunity. Eddies within the tubes themselves where air pockets form and induce "water line attack" can only be avoided by correct design.

Protective coatings of oxysalts, insoluble sulphide or lead are very interesting possibilities. Pre-oxidized tubes have been favored by many engineers. As a matter of fact an oxidized layer formed by low or high temperature annealing will only protect the underlying metal for a very moderate time—perhaps three months is required for the solution of these artificial layers. A premonition of what can eventually be done with certain protectors, however, was discovered when investigating so-called "plug dezincification." It was found that one lot of sea water which had been transported in galvanized iron barrels would not produce this type of action on specimens known to be susceptible, even after prolonged immersion at 50 deg. C. The water was found to contain 0.08 g. Zn per liter. Ordinary sea water to which a corresponding amount of zinc chloride had been added was also found impotent to cause "plug dezincification." Apparently a low concentration of zinc at the surface of the metal changes the physical character of the corrosion product, since this type of corrosion is set up by a colloidal precipitate of zinc oxychloride and carbonate, and since brasses containing more than 35 per cent zinc are immune (the precipitate being visibly crystalline, instead of a colloidal salt acting like a semi-permeable membrane).

[4] It is clear that if this method of protection is to be used, it should be in operation when the condenser first receives water —local action once started can be stopped with great difficulty.

Investigation of Effect of Sulphur in Steel Progressing

Tests to determine the effect of sulphur on rivet steel made at Watertown Arsenal and the U. S. Naval Experiment Station under the direction of the Joint Committee on Investigation of Effect of Phosphorus and Sulphur in Steel (American Society for Testing Materials) have been entirely completed.

The second group of residual sulphur material in this series comprises plate and structural steels, carbon 0.16–0.22 per cent, with sulphur ranging from 0.03 to 0.08 per cent. Four heats of basic open-hearth steel with sulphurs of 0.04, 0.05, 0.06 and 0.07 on ladle analysis have been made for the Joint Committee by the Cambria Steel Co. The heats run: C, 0.20–0.25; Mn, 0.42–0.46; P, 0.01–0.02. The complete history of each heat is known. After a suitable top discard, plates were rolled as follows from each heat:

Six pieces shear mill plate.....20 x 96 x ⅝ in.
Six pieces shear mill plate....15 x 96 x ⅝ in.
Three pieces universal mill plate 20 x 96 x ⅝ in.
Six pieces universal mill plate..15 x 96 x ⅝ in.

Similar material will be furnished the Committee from heats of this grade of steel containing 0.03 and 0.08 per cent sulphur.

The Bethlehem Steel Co. has recently completed the manufacture and fabrication of certain steel for this investigation. Three heats of basic open-hearth steel were manufactured having carbon contents of 0.18–0.22, 0.35–0.45 and 0.65–0.75, typifying plate, forging and rail steels respectively. The original sulphur content of each heat was 0.04 per cent or below. Iron sulphide was added during pouring, so that for each carbon content there were secured eight ingots with "added" sulphur contents from 0.04 to 0.15 per cent. Material from the 24 ingots has been furnished for test in the form of 1-in. rounds and in flats approximately 4 x 1 in. in dimension.

In order to compare the effects of "added" and "residual" sulphur, available scrap from three low-sulphur ingots of each heat was remelted, producing steel with "residual" sulphur of approximately 0.08 per cent; and three of the higher sulphur ingots from each heat were remelted, producing steel with residual sulphur of approximately 0.13 per cent. This material will also be fabricated in the form of rounds and flats for tests.

Regulations on Sale of Alcohol

The Internal Revenue Bureau has issued a warning that denatured alcohol offered for sale must be advertised and marked as denatured or completely denatured alcohol, with a poison label, and not simply as "alcohol."

It is charged that persons who sell denatured alcohol at retail frequently advertise that "alcohol" is for sale, without any qualifying words such as "denatured" or "completely denatured," in violation of section 17 of the national prohibition act and section 97 of regulations 60. It is charged that such retailers also frequently sell completely denatured alcohol without placing on the container thereof the cautionary "Poison" label required by article 108 of regulations 61.

Inasmuch as such illegal practices menace the health and lives of persons who might be misled into believing that the alcohol is pure, parties guilty of such practices are warned to discontinue them immediately. Violations will be reported to the United States Attorney for prosecution.

The German and American Synthetic-Ammonia Plants*—II

Comparison of the Methods of Manufacturing Hydrogen and Nitrogen at Oppau, Germany, and at Sheffield, Ala.—Differences in Processes for Supplying Nitrogen—Construction and Operation of the Carbon-Monoxide Converters

By R. S. TOUR

THERE are, in reality, four distinct types of gas produced at Oppau: (1) Water gas made from coke, as the main source of hydrogen for the synthesis of ammonia, (2) lean gas as the main source of nitrogen for the ammonia, (3) power gas (producer) as the main source of power throughout the plant, and (4) nitrogen from liquid air for adjustment of gas composition in the synthesis of ammonia. These gases and gas mixtures are generated according to standard methods and in standard equipment.

Water-Gas Production at Oppau

The water gas and lean gas are made in 12-ft. shell Pintsch type generators of which there are 15, 12 with, and 3 without, revolving grates. In addition there are two or three experimental generators where an attempt is being made to develop a lignite burning water-gas machine, and a slagging type producer. The fuel used is a high grade of coke normally to be delivered from byproduct coke ovens on the grounds. These ovens are to have a capacity of 700 tons of coke per day, the excess gas from which may be used for power purposes.

The water-gas machines deliver about 2,500,000 cu.ft. each per day (at 60 deg. F. and 30 in. Hg) with a fuel consumption of 40 to 42 lb. per thousand. The normal operating capacity of the water-gas machines is 25,000,000 to 30,000,000 cu.ft. per day, with a coke consumption of 550 to 650 tons. The generators are operated on one- to two-minute "blows" and three- to five-minute "runs," the latter being "up," "down," or "mixed," according to requirements. The steam used is 175 lb., 125 deg. F. superheat. The water-gas consumption is approximately: 4 per cent CO_2, 43 per cent CO, 49 per cent H_2 and 4 per cent N_2. Attention is called to the fact that a high nitrogen content is not objectionable here since there is to be a later admixture of high nitrogen gas. Any steps tending to decrease the loss of hydrogen in the stack, however, are desirable.

The lean gas (producer gas made from selected fuel) consists merely of water gas to which is added the blast gas of the blow period. This allows of continuous, rather than intermittent, operation of the machines producing this gas. In the water-gas machines the blast gas volume is nearly twice the water gas generated. Thus the capacity of the machine producing lean gas is about 7,000,000 cu.ft. per day, with a fuel consumption of about 15 lb. per thousand. The lean gas required is about half the water gas; hence two generators supply the necessary capacity and consume some 100 tons of coke per day, coke being used to produce a methane-free gas. The lean gas composition is approximately 5 per cent CO_2, 30 per cent CO, 15 per cent H_2 and 50 per cent N_2.

*For Part I see CHEM. & MET. ENG., vol. 26, No. 6, p. 245, Feb. 8, 1922.

The water gas and lean gas pass separately through standard wash-boxes and water scrubbers packed with Rauschig rings and on to two water-gas storage and relief holders of 500,000 cu.ft. capacity each, and one lean gas holder of like size. There are no purifiers for the gas and no waste-heat boilers on the machines.

Manufacture of Producer Gas

Producer gas (power gas) is made according to standard procedure in twenty-three B.A.M.A.G.[4] continuous producers with revolving grates. These are situated in the same building with, and in a row directly opposite, the water-gas machines mentioned above. The machines are of 16-ft. shell diameter and burn a fuel of part lignite briquets (cylindrical 2 in. by 4 in. in diameter) and part hard coal, the latter being advisable for maintaining good fuel bed conditions and producer capacity. The producers deliver about 2,500,000 cu.ft. per machine per day, with a fuel consumption of 20 to 22 lb. per thousand (at 60 deg. F. and 30 in. Hg). This gives a plant capacity of about 50,000,000 cu.ft. per day and a daily fuel consumption of about 500 tons.

In view of the high combustion rate for the type of fuel in the producers, a low steam proportion is used, a high fuel bed temperature is maintained and the gas made is high in nitrogen and of low heating value. A mean composition would be 4 per cent CO_2, 27 per cent CO, 4 per cent H_2, 2 per cent CH_4, and 63 per cent N_2. The purification of the producer gas is naturally more extensive than that of the water gas. First, a standard water scrubber is used, followed by a centrifugal water washer or tar extractor and a cyclone separator. The clean gas then passes to a

2,000,000-cu.ft. holder feeding the gas engines throughout the plant.

Production of Pure Nitrogen

Free nitrogen is necessary for incidental purposes about the plant and large quantities are essential for continuous adjustment of the composition of the hydrogen-nitrogen mixture required for the synthesis. The mixing of the water gas, described above, with the lean gas yields a mixture somewhat low in nitrogen and purposely made so, since nitrogen in variable quantities in the form of air is to be later added for internal combustion and heat maintenance. The variation in this combustion air, as well as operating variations in gas compositions and in proportioning of lean gas to water gas, may lead to quite wide variation from the 3:1 hydrogen-nitrogen mixture finally required for ammonia synthesis. Since any slight excess of either constituent rapidly accumulates in the ammonia-synthesis circulating system where the ammonia removed represents exactly three parts hydrogen to one part nitrogen, it becomes necessary continuously to adjust the composition of the gases. It is obvious that this adjustment is more economically made by adding pure nitrogen rather than pure hydrogen, and hence the initial gas mixture is purposely maintained sufficiently low in nitrogen to allow for more than the subsequent operating variations.

The nitrogen plant at Oppau consists of 6 distillation columns of the Linde type and 7 air compressors direct-connected to gas engines. The installation was old and a new plant has been built similar to the above and having a capacity of about 1,800,000 cu.ft. of nitrogen per day. If half of this capacity is regularly used for adjustment of composition, it represents about 13 per cent of the nitrogen fixed and allows for an average nitrogen deficiency of 3 per cent of the total gas mixture entering the ammonia synthesis system.

The water gas, as a source of hydrogen, and lean gas, as a source of nitrogen, are delivered from their respective holders by turbo-exhausters equipped with water injectors for saturating the gas and followed by cyclone separators for removing excess water. The gases then pass through meters and to a mixing main equipped with turbo-blowers for mixing the gas and for feeding it to the converter system. The two gases are fed to the mixing main in such proportions as finally to yield a purified gas, which, as previously explained, is somewhat deficient in nitrogen.

Water-Gas Production at Sheffield

There was but one type of gas produced at Sheffield: viz., a water gas with varying nitrogen content—this gas being produced according to standard methods and in standard equipment. The latter consists of six 7½-ft. shell water-gas generators; the fuel used was a high grade of coke.

The capacity of each water-gas machine at Sheffield was about 0.7 million cu.ft. of water gas per day. The plant capacity was about 3,500,000, or about sufficient for the rated ammonia capacity. However, the contemplated operation called for a number of gas-fired furnaces in conjunction with the process and had their use not proved unnecessary, the gas plant would have been much under capacity. The water gas from the machines passed through standard wash boxes and water scrubbers and on to a storage and relief holder of 500,000 cu.ft. capacity. From this the gas was fed by holder pressure through iron-oxide purifying boxes on the way to the carbon-monoxide converters. The purifiers caused some trouble due to excessive friction and were soon found to be unnecessary. It will be noted that the Germans did not use any purification process.

Methods of Supplying Nitrogen

The plant had been designed to operate on a high-nitrogen water gas where all the nitrogen necessary for the later synthesis was injected as air into the generator during the gas-making period. This method, although generating a mixed gas, is not fundamentally different from the procedure used at Oppau, though the former may be more adaptable for small plant use. In either case, the nitrogen comes from blast gases and the air used has made available heat within the fuel bed. Where possible, it is naturally more desirable to operate one of the machines as a continuous producer and the other machines for straight water-gas production. The Sheffield plan of using only part of the blowing air in each machine simultaneously with steam during gas production involves many operating difficulties, the most important of which is the variable composition of the effluent gases. Although both the air and the steam can be measured, the proportion of steam

decomposed, and therefore the resultant proportion of hydrogen, will be dependent upon the grade of fuel, upon the temperature and cleanliness of the fuel bed, and upon operating variables in general, and will also vary enormously from the beginning to the end of each "run."

It was found that later in the process very considerable air injection into the carbon-monoxide converters was required for internal combustion and maintenance of temperature, and this reduced the quantity of nitrogen the mixed gas might carry from the water-gas machines. In view, therefore, of the difficulties in operating the gas machines and the actual low nitrogen content desired, the final operation at Sheffield developed into straight water-gas manufacture with all of the nitrogen added later by air injection. The latter type of operation, although it may be necessary, is fundamentally inefficient, since air injection into the gas with combustion of the latter involves a definite loss of hydrogen or carbon monoxide (later yielding hydrogen), whereas the nitrogen available from the gas generator blast represents no loss of fuel. Complete nitrogen supply by air injection and combustion in the gas involves a loss of 25 per cent of the hydrogen obtainable from a given volume of water gas with

NITROGEN SUPPLY BY AIR INJECTION AND COMBUSTION

	Pure Water Gas (Cu.Ft.)	After Combustion of 333 Cu.Ft. of Air With CO (Cu.Ft.)	With H_2 (Cu.Ft.)	After CO Conversion (Cu.Ft.)	Analysis (Per Cent)
Carbon dioxide	40	177	40	449	29.2
Carbon monoxide	440	303	440	31	2.0
Hydrogen	520	520	383	792	51.6
Nitrogen	....	264	264	264	17.2
	1,000 Cu. Ft.			1,536 Cu.Ft.	100.0

NITROGEN SUPPLY BY BLAST-GAS ADDITION

	Pure Water Gas (Cu.Ft.)	After Adding 514 Cu.Ft. Blast Gas (Cu.Ft.)	After CO Conversion (Cu.Ft.)	Analysis (Per Cent)
Carbon dioxide	40	61	601	29.2
Carbon monoxide	440	581	41	2.0
Hydrogen	520	520	1,060	51.6
Nitrogen	...	352	352	17.2
	1,000 Cu. Ft.		2,054 Cu. Ft.	100.0

nitrogen added as blast gas, and thus increases the fuel consumption by 33 per cent.

The results given in the preceding tables have been calculated on the basis of identical operation and efficiency in each case. It is to be noted that it makes no difference whether carbon monoxide or hydrogen is burned by the air in the first case; values are, however, given for both.

During operation at Sheffield the blue water gas produced had the approximate composition: 4 per cent CO_2, 44 per cent CO, 50 per cent H_2, and 2 per cent N_2. The coke consumption was about 60 lb. per thousand cubic feet, and the labor charge high. A high fuel and labor charge is to be expected in view of the small size of the machines. After the close of plant operation, the Nitrate Division tried an improvement on the machines with great success. This consisted mainly of secondary blast within the fuel bed, allowing more rapid and uniform heating during the blow and improving the fuel efficiency by reducing carbon-monoxide losses in the blast gases. Test showed that the fuel consumption had been reduced to 40 lb. of coke, or equally as good as the German operation with their 12-ft. machines.

There was no pure nitrogen produced at Sheffield for adjustment of composition. Experience with the control of the nitrogen content, however, proved that had the plant produced any quantity of ammonia, adjustment of composition would have been necessary. Thus, had the hydrogen to nitrogen ratio been 3.3 to 1.0 (and that is not bad operation) rather than 3.0, capacity operation within three or four hours would have caused the ratio in the ammonia synthesis system to reach 5 to 1.

Carbon-Monoxide Conversion at Oppau

The mixture of lean gas and water gas after being proportioned properly has the approximate composition: 4 per cent CO_2, 39 per cent CO, 38 per cent H_2, and 19 per cent N_2. This mixed gas has added to it a large excess of steam and passes through heat interchangers to the converter where a catalyst aids the exothermic water-gas reaction: $CO + H_2O \leftrightarrows CO_2 + H_2$. The converted gas passes back through the heat interchangers followed by a condenser to remove excess steam.

The steam addition at Oppau is accomplished by an apparatus which we may call a steam interchanger, whereby much of the steam condensed from the converted exit gas is made available to the inlet mixed gas. This cooling and condensation of exit gas is brought about by direct contact with a counter-current spray of cold water in a condenser shell 12 ft. in diameter and 60 ft. tall, filled with suitable packing. The water emerges from the bottom of the condenser at nearly boiling temperature and is fed to the vaporizer, similar in all respects to the condenser, where the cold inlet gas is heated and supplied with steam from the hot water. The water is cooled by this treatment and again repeats its cycle through the condenser.

Two sets of steam interchangers handle the entire plant capacity, interchanging some 1,400 tons of steam per day per pair. The total steam required for the nearly 40,000,000 cu.ft. of inlet mixed gas is about 4,000 tons (i.e., 4 volumes per volume of inlet gas), 300 tons of which actually react, and an additional 1,000 tons of which are not interchanged but lost as condensate. The 2,700 tons that are interchanged to the inlet gas are augmented by 1,300 tons of low pressure steam injected into the mixture just before it enters the converter system.

Path of Gases

There are 24 converter sets, complete with heat interchangers, 12 sets in each of two adjacent buildings. All sets are fundamentally the same and have a capacity of about 75,000 cu.ft. of dry inlet gas per hour. In each building the sets operate in parallel, taking inlet gas and steam from a single main and discharging to one main. The path of the gases in each set is through a large interchanger followed by a small one, which raise the gas temperature to some 500 deg. C. when it passes through the carbon-monoxide catalyst, there further rising in temperature about 60 deg. C. due to reaction heat. All but about 3 per cent of the carbon monoxide in the gas is converted at this point. The gas then passes back through a second catalyst bed at a lower temperature, at the entrance to which air is injected and, if necessary, additional steam. The carbon monoxide is here reduced to 1.5 per cent and the gas passes on through the last heat interchanger.

The heat interchangers consist of large sheet-iron shells with an internal nest of tubes; the inlet gas passes around the tubes and exit gas through the tubes. This path is by far the better, since the external radiation losses are decreased, as well as the temperature transfer head improved. The larger interchanger is about 6 ft. in diameter by 30 ft. high, while the smaller is 6 ft. by 20 ft. high. Both shells are lagged with about 8 in. of magnesia.

The Catalyst Beds

The two catalyst beds are in a heat-insulated shell about 12 ft. tall. A horizontal cross-section of the shell would be rectangular (10 ft. by 30 ft.) with round corners. A vertical partition divides the shell into two independent compartments. The catalyst in each compartment is placed on five superposed trays all within a container to conduct the gas downward through the catalyst.

The use of two catalyst beds in series, the second at a lower temperature, represents a decided improvement in operation. The water-gas reaction, as well as the later ammonia reaction, has a much more favorable equilibrium at lower temperatures, but also a much slower reaction rate. Thus, it is desirable to accomplish most of the reaction at higher temperature and

follow that by low temperature catalysis. If air or oxygen be available during low temperature catalysis, the oxidation of the carbon monoxide will be much more readily carried to its equilibrium value. Further, the air supply may be adjusted to supply internal heat within the system, if such be necessary for maintenance of temperature. The catalysts used for the carbon monoxide conversion depend for their activity mainly upon iron oxide with chromium oxide as a promoter. Cerium and thorium oxides have also been tried as promoters.

Great care is taken in the control of the converters. Each set is supplied with some 50 base-metal thermocouples reading on an indicating millivoltmeter. There are manometers to read pressures in different parts of each set and Pitot tubes to measure flow of steam and gas and air. The gas obtained at the exit of the converter sets has the approximate composition: 29.5 per cent CO_2, 1.5 per cent CO, 53 per cent H_2, and 16 per cent N_2. The volume of inlet gas has been increased about 35 per cent in the converters, so there is a daily converted gas production of 50,000,000 to 60,000,000 cu.ft. (representing 25,000,000 to 30,000,000 cu.ft. of hydrogen). This converted gas, after condensation of moisture, passes back to the metering house where the inlet gas was measured and mixed. After the gas has been metered, it passes to another 500,000-cu.ft. holder, from which it is directly available to the compressors.

Carbon-Monoxide Conversion at Sheffield

The conversion process used at Sheffield was much the same as that at Oppau, especially so toward the close of operation. The gas from the holders was delivered to the converter set by positive pressure exhausters. No steam interchangers were used, but all the steam, 200 lb. per thousand cubic feet of gas (about 4 volumes per volume of inlet gas) was fed from the steam main and all the excess steam on the exit gas was condensed. This method of operation requires about three times as much steam and condensing water as does the method described for Oppau. The steam supply, as the plant was installed, was to feed through a standard gas-fired tubular steam superheater which was to furnish the additional heat required to maintain the converter system at operating temperature. This method of heat supply is inefficient in two ways: (a) The steam superheater efficiency is directly involved and this is low, especially for the large superheat required at Sheffield, and (b) heating the inlet mixture decreases the temperature head across the heat interchangers and their heat transfer is proportionally decreased. On the other hand, air injection for internal combustion of gas at the catalyst chamber yields nearly 100 per cent thermal efficiency and also increases the temperature head across the interchangers, thus improving their heat transfer. After burning out the steam superheater, the internal-combustion method was tried with great success and with a large saving in gas consumption. The steam then was injected as low pressure steam.

The condensation of the excess steam at the exit of the system was accomplished by two surface condensers operating in parallel. These were soon found to be of only a fraction of the necessary capacity and additional condensers were installed. Very little experience is available for the design of condensers for a mixture of 75 per cent steam and 25 per cent gas. Some experiments made by the Nitrate Division looking toward the redesign of the condensers indicate that the coefficient of heat transfer under such conditions is of the order of one-tenth that in standard condensers. The actual value, however, is largely dependent upon the lineal velocity of flow of the steam-gas mixture and of the water. Efficient condensation at the exit of the carbon-monoxide system is important, especially if the mixture passes on directly to the compressors, as it did at Sheffield. The condensate is of no value, due to dissolved gases, and the only reason for using surface, instead of jet condensers, would be to make use of the heated cooling water.

Operation at Sheffield

There was but one carbon-monoxide converter set with a rated capacity of 30,000 cu.ft. of inlet gas per hour, in the operating unit. (Unit No. 1.) This consisted of one catalyst chamber with three heat interchangers, the inlet gas passing through the first and smallest of the three before steam injection. The general construction of the interchangers was much the same as that described for Oppau, although with much less transfer surface. The heat transfer through the interchangers was not very satisfactory and accounted for the fact that the system was so far from self-maintaining in temperature.

There was but one catalyst chamber, of circular section, 8 ft. in diameter and 6 ft. deep, into which was first charged 120 cu.ft. of catalyst in a single bed about 2½ ft. deep. In operation this bed rapidly developed high friction to gas flow, due to crumbling and packing of the catalyst, which is physically delicate and can not withstand the accumulated friction and weight of a deep bed. The converter was repacked with about half the depth and operated quite satisfactorily thereafter, although the Oppau method of placing the catalyst in shallow layers on superposed grids is the best solution.

During operation the catalyst inlet temperature was maintained at 500 deg. C. and the rise in temperature across the catalyst bed was 50 to 60 deg. C. As mentioned before, this heat liberated was far from sufficient to maintain the system at its proper temperature and air was injected for internal combustion at the top connection of the converter through what was known as the auxiliary burner. The air combined with the gas as a flame above the catalyst and not within the catalyst bed. Flame combustion is the better method where any large quantity of heat development is necessary since it prevents too large a temperature gradient through the catalyst bed itself. No provision had been made for ignition of the auxiliary burner, but this difficulty was soon overcome. The more flame used, the more nitrogen is added and the less is to be introduced at the gas house.

Operation at Sheffield required that about 75 per cent of the total nitrogen be added at the burner and finally, in view of the difficulty of nitrogen control in the gas machines, all of it was added through the burner, the excess heat developed being wasted by partly bypassing the heat interchangers.

No secondary converter was used at Sheffield, although the writer, without being acquainted with the process in use at Oppau, tried experimentally in November, 1918, what he called an "oxidizer" in the converter set of Unit No. 2 (not the one in operation). The oxidizer was merely an additional converter connected in the line of the return gas from the primary converter after the gas had passed through one heat interchanger. The oxidizer was charged with the same catalyst as the primary converter, operated at a lower temperature than the latter, and had air injection, but not through a burner, oxidation being desired within the catalyst. For various reasons the experiment was not continued long enough to give decisive data. However, the standard operation at Oppau is somewhat similar to that attempted with the "oxidizer."

During operation, temperatures were measured by 4 or 5 platinum resistance pyrometers; pressures were indicated by manometers in the system; and gas, steam and air inlet volumes were measured by Venturi meters. The converted gas composition was about 29 per cent CO_2, 3 per cent CO, 51 per cent H_2, and 17 per cent N_2; the residual carbon monoxide was about the same as at the first catalyst exit in Oppau, although the nitrogen was higher, since no further nitrogen addition was contemplated. The converted gas passed directly from the condensers to the compressors, a Venturi meter on the line measuring the compressor intake. In the suction line to the compressors was connected a larger buffer tank to absorb the pulsations and also a 75,000-cu.ft. holder to take up the slight variations between supply and demand.

(*Part III will appear in a subsequent issue.*)

Manufacture of Soap in Brazil

Some interesting facts relative to the soap industry in Brazil are presented in the Feb. 6, 1922, issue of *Commerce Reports.*

Brazilian companies are able to turn out all of the laundry and cheap house soap required in that country, using as a basis the fats and greases obtained in their immediate neighborhood. A great many types of toilet soap are also being produced, and although it is said that Brazil is independent from outside sources for goods of this nature, it is admitted that the foreign product is superior to the native goods.

The chemicals required, including rosin, soda ash, coloring matter and perfumes, must all be imported. Rosin comes exclusively from the United States, while England has had almost a monopoly on the soda trade.

The yearly importation of soda averages 10,000 tons, which makes it a business well worth striving for. It was thought a few years ago that recently formed domestic companies would be able to supply the local market, but with the resumption of free trade in this material after the war, it was found that the domestic product was more expensive than the imported, and this at once killed all prospects of local competition.

The finer materials, including essential oils and coloring matter, play a comparatively small part in the soap-making industry, and European houses have been able to get practically all of the business up to the present time.

To compete successfully for this business, active agents, stock for immediate delivery and attractive prices are essential.

Manufacture of Synthetic Cast Iron in the Electric Furnace

Synthetic Iron Produced in the Electric Furnace on the Pacific Coast—Detrimental Effects of Excessive Dry Slags—Comparative Costs of Manufacture for Various Load Factors

By W. L. MORRISON, E. M.

THE MANUFACTURE of synthetic cast iron, so called to distinguish it from the blast-furnace product, has been carried on in various parts of this country and abroad.

The opportunity for research in connection with the manufacture of synthetic iron and the melting of cast iron in the electric furnace is very great.

The first work on synthetic pig iron in Portland, Ore., was started in the summer of 1918. The furnace used was one which had been operating on ferromanganese, being of the three-phase, stationary type, with open top, three 17-in. electrodes being used. The furnace had an electrical capacity of 600 kw. Before starting on the pig iron a 9-in. arch was placed on the furnace with water-cooled bronze bushings for the electrodes. The ends of the arch were left open for charging the furnace.

In the latter part of 1919 a 2-ton furnace of the stationary type was installed for the production of gray iron castings from turnings and steel. The shell is 7 ft. wide, 11 ft. long and 6 ft. high, made of ¾-in. boiler plate reinforced with ship channel. A tap hole was cut in the side of the shell about 12 in. in diameter; a few inches below this main tap hole a 3-in. hole was cut to be used should the bottom be lower at any time than could be drained from the upper hole. The shell was set on I-beams on a concrete foundation, of such height as to allow a 5-ton buggy ladle to pass under the spout. A charging platform was erected at either end of the furnace on the same level as the top of the furnace, to facilitate charging, which was done under the arch at the ends.

The furnace was supplied with electric current by three Acheson graphite electrodes 8 in. in diameter operated by the so-called hand controls. Current was received at 11,000 v. and stepped down to 70 v., using three Packard Electric Transformers, 250 kva. each, the transformers being delta connected. The transformers were of the outdoor type, installed in the open without covering, and no trouble was experienced during the rainy seasons.

Furnace Linings

The side walls of the furnace were lined with highest grade firebrick to a thickness of about 18 in. The furnace bottom was made up with 8 in. of firebrick and 12 in. of rammed coke dust and tar. Between the firebrick and the shell 1 in. of asbestos cement was used for heat insulation. The asbestos insulation gave excellent results, as the furnace shell remained cool enough to hold one's hand on it even during continuous operation.

The carbon bottom lining gave quite satisfactory results, but was troublesome to repair on account of having to warm the coke and tar mixture and ram into place in a hot furnace; furthermore, the supply of fine coke was limited and there was no economical means of pulverizing more. The furnace bottom was repaired weekly without interrupting the operation during the week. The linings lasted from 6 to 8 weeks, operating one and two shifts. The metal poured was free from blow-holes, but at first somewhat low in carbon, as the carbonizer used was all anthracite coal; by operating with a larger excess of coal the carbon content was brought up. The first furnace bottom had to withstand very rough usage on account of considerable experimental work with different carbonizers and fluxes.

After the first 6 weeks of operation the carbon bottom was abandoned and a silica bottom substituted. This was made up of silica rock crushed to about ¼ in., silica sand and about 10 to 15 per cent high-grade fireclay and brickbats. The silica bottom was repaired every 2 weeks, sometimes weekly, depending on conditions. Under normal conditions the bottom gave very satisfactory results.

Furnace Bottom

In order to eliminate the repairs to the furnace bottom it was suggested to use a solid firebrick bottom. A high-grade firebrick was obtained and, when repairing the side walls, a brick bottom was placed in the furnace to a depth of 13 in. in addition to the 8-in. firebrick lining already in. The upper course was stood on end to prevent the brick from floating; hytempite cement was used to bond the brick, but after several days' operation some of the brick began to float, and upon examination it was found that about half the brick had been dissolved by the metal. The furnace was drained and repaired, the brick bottom being removed and a rammed silica bottom substituted. While removing the old brick bottom it was noticed that the iron had run in between the brick and become lens shape due to the action on the brick. Analysis of these specimens showed that silicon and aluminum had been absorbed. Analysis of lens shape mass showed silicon, 5.1 per cent; aluminum, 1.25 per cent. Analysis of iron produced showed silicon, 2.25 per cent; aluminum, 1.12 per cent. The aluminum is high in the iron on account of the iron absorbing it from the brick bottom; iron made on the silica bottom had less than 0.1 per cent Al.

In the long run the silica bottom appeared to give the most satisfactory results both as to operation and quickness of repairs. The repairs were usually made at the end of the week and required 2 to 4 hours.

The arch of the furnace was made up of 9-in. wedge firebrick giving a spring of 15 in. in the 7 ft. An opening was left in the ends approximately 20 in. wide for charging and stirring the metal. Brick-lined doors were fitted to the openings and supported by chains on pulleys and balanced by weights. Bronze water-cooled bushings were fitted in the roof where the electrodes entered the furnace. The usual life of the lining and arch operating two shifts was 2 months.

In the operation of the 2-ton furnace smelting turn-

ings, and borings, the most efficient operation was obtained by continuous charging and tapping at regular intervals. In this way the light materials were preheated before reaching the melting zone. The furnace was fed about every 30 minutes and tapped at intervals of 2 hours.

After thoroughly drying and baking the furnace lining, 200 or 300 lb. of anthracite coal is charged on the bottom, then, if turnings and borings are used, these are charged along with the requisite amounts of coal, silicon, manganese, lime and spar. When using the continuous method it is desirable to weigh up small charges—i.e., 500 to 1,000 lb. A representative charge would be: 500 lb. turnings, 50 lb. anthracite dust, 20 lb. 50 per cent ferrosilicon, 2 lb. 80 per cent ferromanganese, 5 lb. lime and 2 lb. spar. By using small charges the silicon and manganese are more evenly mixed with the turnings, and a more uniform product is obtained.

The first question naturally to be asked is, Can the metal be produced hot enough by continuous charging? The writer has never known of a cold heat by this method of operation using turnings and borings, except when the electric power failed for several hours.

If it is desired to run heavy scrap such as burned grate bars or steel scrap, this heavy scrap is added immediately after tapping, the electrodes being raised to prevent breakage. The continuous method can be used only with the small light scrap, or so-called shoveling scrap, the silica, coal, etc., being added with the scrap.

About every 2 days the entire charge in the furnace is completely melted to permit the accumulated slag to be removed. The slag is in the form of crusts and is removed by means of a long-handled fork.

In making pig iron the slag has to be eliminated more often than when making iron for use direct in castings, because more lime is required for the sulphur removal. When melting cast borings and steel turnings without lime flux the sulphur content of the metal rarely exceeds 0.07 per cent provided the cast scrap does not exceed 50 per cent of the charge. There is a loss of sulphur of from 0.01 to 0.03 per cent during the melting without lime additions.

Carbonizing

The carbonizing of the iron is very simple if the carbonizing material is finely divided (½ in. and smaller), and used in excess.

The first attempts at carbonizing were very discouraging, because the materials used were all large size. Charcoal was first tried but not with very satisfactory results. The charcoal was of about 4 in. average size, being used just as it came from the pit. The electrode would arc in time on the charcoal and would not heat the metal nor carbonize it, the result being cold metal and low carbon (2.80 to 3.00). Coke breeze was next tried with somewhat better results, but the excessive ash and the fact that coke up to 2 in. was in the breeze made this material undesirable. Finally, a few tons of anthracite dust of slack was obtained from a ferromanganese smelter and tried. The first attempt was not very promising, but upon larger additions being made, a carbon content up to almost any desired amount could be attained. The ash in the anthracite coal ran about 5 per cent, while that in the coke ran as high as 25 per cent.

Charcoal was then crushed and found to be equal and in some ways superior to anthracite coal, but on account of the excessive cost of charcoal and having no facilities for crushing, anthracite coal was adopted for carbonizing. The relative cost and value of different carbonizers is given below:

Material	Ash, per Cent	Fixed Carbon, per Cent	Cost per Ton
Anthracite coal	5.0	88.00	$11.00
Charcoal	2.5	76.00	28.00
Coke	21.00	67.00	14.00
Coke	14.00	75.00	18.00

After a series of experiments it was found that a complete and even carbonization could be effected by operating with a cover of coal of from 4 to 6 in. over the metal. This perhaps explains why the continuous method of charging works so successfully with the light scrap. During operation the coal is in a state of incandescence, and the molten iron filtering down through this hot mass of fine coal is carbonized completely due to a combination of high temperature and large exposed area.

The metal is maintained at a white heat due to the hot bed of coal directly over it, the coal separating the semi-fused and cooler scrap from the molten metal. Samples were taken at the beginning and finish of a tap and the analysis was found to be very uniform.

When making gray iron for direct use in the foundry care must be used not to have too high a carbon content and a separation of graphite in the molds. In case the preliminary sample shows an excess of graphite, this can be cut by adding a few hundred pounds of steel scrap. When the excess graphite begins to show in the castings, it is best to cut down the amount of coal in the charge, or omit it altogether from a few charges.

Should it be desired to make a lower carbon iron, or so-called semi-steel, only a small amount of carbon should be added, then if the fracture appears too low the carbon may be raised by adding more coal and boiling the metal with a green pole, or by boiling without the coal addition, as sufficient coal is usually on the bed to completely carbonize when boiling is resorted to. When making the lower carbon irons it is more desirable to run single charges and melt down the entire charge before tapping, as better control of the carbon may thus be had.

An all-steel scrap charge gives a better iron of low carbon content (3.00 per cent) than can be had from cast borings or a mixture of cast iron and steel, being freer from impurities and lower in phosphorus. The iron made from an all-steel scrap mix is very fluid and has plenty of "life," even more than iron of similar analysis from the cupola.

In the production of pig iron one does not need to be so careful about the high carbon content. Pig iron running 3.75 to 4.25 per cent total carbon is readily made in a furnace operating with a thick bed of the proper size material and the right voltage between phases (60 to 75 volts).

In order to see what the cupola could accomplish in the way of carbonizing, a charge of 500 lb. of boiler scrap was run through the cupola along with the requisite amount of lump ferrosilicon. The iron produced was close grained but machined readily. The analysis of the iron produced from boiler punchings in the cupola is as follows:

	Per Cent		Per Cent
Combined C	0.96	Mn	0.35
Graphite C	2.02	P	0.04
Total C	2.98	S	0.08
Si	2.54		

This metal did not have the fluidity that metal of

similar analysis tapped from the electric furnace, although both appeared to have about the same temperature at the time of tapping. The cupola metal set very quickly after being poured in the mold and left a small skull in the ladle. The metal was sound and free from blow-holes. The electric iron made from boiler punchings was very fluid and set slowly in the mold; it poured like oil from the ladle, leaving no skull.

Basic Slag

Lime is added to the charge for the sole purpose of lowering the sulphur content in the finished metal. The addition of lime has been found necessary only when making pig iron to specifications, the high limit ranging from 0.03 to 0.05 per cent sulphur. The basic slag was run on a carbon bottom, also on a silica bottom. One reason why the basic slag worked so well, using an acid furnace, is due to the fact that a very heavy bed of coal held the slag and kept it out of contact with the side walls of the furnace. As a matter of fact, the side walls at times had a tendency to build up with accumulation of slag crust, and spar would have to be added in increasing amounts to cut the slag from the side walls. The iron filtering through the bed of coal and basic slag is both cleansed and carbonized at the same time.

When using lime it is best to add some spar to prevent the lime from entering the metal. Lime under certain conditions appears to have a very deleterious effect upon cast iron, due no doubt to the concentrated heat of the arc-forming carbides of calcium which are absorbed to a greater or less extent by the iron at existing temperatures unless the calcium carbide is in such dilution in the slag by the aid of spar as not to be readily absorbed. The proper control of temperature also aids in preventing the absorption.

The effect of calcium compounds in cast iron is very similar to that produced by aluminum carbide; the iron on being poured has the appearance of burned iron if the total carbon content is not above 3.45 per cent. The iron when poured in green sand molds has a tendency to develop blow-holes beneath the skin of the metal.

However, if the total carbon content is above 3.50 per cent, a very good cast can be made, but the iron does not have the life of ordinary iron. If the total carbon content exceeds 3.65 per cent, with calcium compounds present, the iron, upon cooling somewhat, becomes sluggish with separation of graphite on the ladle, lumps like large marbles separate out and are readily distinguished when pouring; these lumps break up and appear to be mostly graphite with small amount of slag. At times the ladle of 200-lb. capacity would suddenly start an accumulation of graphite and upon trying to skim this off it was found impossible to do so, and it would have to be pigged. The total carbon on these heats rarely exceeded 3.75 per cent and yet the metal would have 1 to 3 in. of graphite covering it. While this high-carbon metal appeared sluggish, the melting point was very low as compared with ordinary iron.

Effect of Aluminum Upon Cast Iron

The effect of aluminum upon cast iron is pretty well known and has been widely discussed; but the effect of carbides of aluminum upon cast iron has been given little attention.

The subject was brought quite forcibly to the writer's notice when the melter was having trouble with his heat, operating with too heavy a slag, and in trying to raise the carbon content additional slag would be formed from the roof and side walls due to the excessive heat; when the metal was finally poured, if the carbon was under 3.25 per cent, the iron would give the appearance of burned iron, producing blow-holes under the skin of the metal when poured in greensand. No lime was used in these heats referred to. Sometimes the metal would purge from the molds when poured into heavy work. Under similar conditions with iron high in carbon, the castings would be free from blow-holes, but would not be as fluid when poured as metal made under the proper conditions. A scum was noticeable over the metal and would continue to form after being lifted off by the skimmer, otherwise the metal lay quiet in the ladle and to all appearances was good iron. The results noted were very similar to those produced by a dry basic slag.

When the trouble was first experienced, increased amounts of silica were added to see if the blow-holes could be eliminated, but even with silicon up to 4 per cent and carbon 3.00 to 3.25 per cent the blow-holes still persisted. Analyses of various irons showed the aluminum content to run from 0.4 to 1.25 per cent. Upon the addition of water to the borings from these bad heats gases were evolved much more readily than from turnings from other heats.

High Temperature Effects Aluminum Content in Iron

The writer believes that with the intense heat produced by the arc and in the presence of aluminous bearing materials such as the firebrick in large excess, carbides of aluminum are formed and absorbed at the high temperatures as the iron passes through the coal mass. These same aluminum carbides, being very energetic chemically, react with the moisture in the molds and produce the gas holes, giving the appearance of the so-called burned iron.

In cupola practice bad iron often results from the use of cheap fireclays, or running the cupola excessively not, accumulating aluminous slag, which, if not properly fluxed, reacts with the coke; especially if the temperature is very high due to high blast pressure and contracted area in coke bed, the iron may absorb aluminum carbide and produce the so-called burned iron. The writer has noticed that from the same ladle of cupola iron a dry mold casting would be perfectly sound, while a greensand casting would develop blow-holes under the skin of the casting.

A small experiment made by the writer in the East upon the action of vanadium thermit in cast iron recalls a condition which tends to cast light upon the action of aluminum or aluminum carbide on cast iron. A mixture of vanadium oxide and 90 per cent silicon was made into a capsule and placed in the bottom of a 200-lb. ladle, the iron was poured on the capsule—the reaction taking place reducing the vanadium—and was then poured into a greensand mold; the casting was perfectly sound. A second ladle was poured, placing the same size capsule on top of the molten iron in the ladle. After the reaction the iron was stirred and poured into greensand mold, and good casting resulted. All together six ladles were poured using the 90 per cent silicon vanadium mixture in varying amounts and good iron resulted every time.

The experiments were repeated, using aluminum-vanadium oxide thermit mixture, and in every case the iron upon being poured into greensand purged upon standing or developed blow-holes upon machining the casting. Thinking that perhaps the theoretical amount

of aluminum was not enough to give complete reduction of the oxide of vanadium, a 10 per cent excess was added, then increased to 25, and finally double the theoretical amount was added, and in every case blowholes developed. The iron to all appearances after the thermit reaction was as good as any, not showing signs of being wild or gassing. The untreated castings from the same heat were all good. Stick aluminum was added in the last ladle after the thermit reaction, but gave no better results. Ten ounces of aluminum was added to an untreated ladle of iron and after stirring well was poured; the iron produced a sound casting, which tends to prove the iron was all right.

Comparing the results in the electric furnace with the reaction of aluminum and vanadium oxide, the conclusion reached is that the temperature produced by the thermit reaction was sufficient to form aluminum carbide in the iron, which reacted with the moisture in the sand. Aluminum carbide is very unstable and active chemically. If the gas in the iron was due directly to oxides being present on account of the vanadium oxide, then one would naturally expect the silicon mixture to give the trouble, because the heat of reaction is much less than that of aluminum with vanadium oxide.

Carl Buberl, in the July 1, 1921, issue of *Foundry*, calls attention to the fact that "cupola daubing clay affects iron." While Mr. Buberl does not say that the iron absorbs aluminum compounds, he does state that the iron absorbed something from the clay and gave poor castings. When a better grade of clay was used and less slagging encountered, the trouble was less frequent. This all tends to prove my theory regarding the absorption of aluminum carbide at high temperatures. I believe that much of the so-called burned iron from the cupola is not due to excess of oxygen absorbed or present as oxides, but is due to bad slag conditions and contamination from aluminous materials.

The only way to overcome this difficulty both in the cupola and in the electric furnace is by the proper selection of refractories, and by keeping dry aluminous slag off the metal. We have tried various additions to the ladle, also poling in the furnace with a green pole, but once the metal has been contaminated by aluminum you must either raise the carbon sufficiently high to overcome the effect of the aluminum carbide or pig the heat. In cupola practice, of course, it is impossible to raise the carbon, but with the electric furnace one has a somewhat wider range of operation.

There is an excellent field for investigation of the influence of calcium and aluminum carbide on cast iron of varying carbon content at high temperatures, such as are attained in the electric furnace.

Spar

Spar is used largely with basic slags to give fluidity, but when using basic slag on an acid bottom should not be used too freely, otherwise the acid lining is attacked and the basic slag goes over to acid slag. The usual additions of lime and spar were 15 to 20 lb. lime and 8 to 15 lb. of spar to the ton of metal melted. The thick bed of coal also aids in keeping the slag from the sidewalls of the furnace.

The sulphur content of the charge is reduced during the melting as the molten metal passes through the coal bed and basic slag. For this reason the acid-lined furnace would not work as well in the duplex process operating a basic slag, for in this case the furnace is usually not operated with a thick bed of coal which holds the slag. However, there is a possibility that a modification of this method of refining might be adopted in the duplex process and work out quite satisfactorily.

Analyses of several consecutive heats are given in Table I to demonstrate the control of the electric furnace on synthetic iron.

TABLE I—ANALYSES OF HIGH-MANGANESE PIG IRON

Heat No.	Silicon	Total Carbon	Manganese	Phos.	Sulphur
71	2.87	3.59	4.02	0.14	0.03

104	2.69	3.65	0.61	0.17	0.03

The irons analyzed were all made in the electric furnace with an acid lining, using lime and spar in the charge. Furnace was operated continuous charging with about 6-in. bed of coal over the molten metal. The charge consisted of mixed turnings and borings, which accounts for some variation in the silicon content of the finished metal. Using all steel turnings, the silicon content can be held much more uniform. When an all cast boring charge is used the amount of coal needed is very much less, and this must be taken into consideration to avoid metal too high in carbon.

Comparative Cost of Electric Furnace Operation

One great drawback to an electric furnace operating intermittently is the sliding scale power rates as now existing in many localities. A furnace should be operated 16 hours a day to obtain economical operation and a good power rate. When business is slack and the foundryman is pouring a limited tonnage each week, perhaps operating less than one shift per day, he must pay a greatly increased rate besides getting a lower furnace efficiency.

For this reason a foundryman contemplating a furnace installation should figure a furnace of such capacity as to operate 24 hours when the foundry is at capacity, instead of operating only the one shift. Then when conditions arise to cut the capacity down to say 25 per cent of normal, the electric furnace can still operate practically one shift with economy.

For the sake of comparison I give in Table II comparative costs of one-, two- and three-shift operation.

Summary of Operating Costs

In summing up these figures we find the operating costs as follows:

Total cost per net ton of iron at the spout: One shift, $40.33; two shifts, $30.18; three shifts, $27.40. These figures do not include fixed charges, which vary in different plants, but are given to show the actual necessity of operating the electric furnace at least two shifts to get a desired economical operation. This does not mean that the remainder of the plant or foundry need go on a two-shift basis. The figures are based on actual opera-

TABLE II—COMPARATIVE COSTS OF ONE-, TWO- AND THREE-SHIFT OPERATION

Figures based on 2-ton furnace, 750-kw. electrical capacity

Cost of materials:		
Scrap (turnings and borings), net ton		$10.00
Power:		
1 shift, 1.25 c. kw.-hr.		
2 shifts, 1.00c. kw.-hr.		
3 shifts, 0.80c. kw.-hr.		
Coal (anthracite), net ton		15.00
Electrodes (graphite), lb.		.24
Lime (in bbl.), net ton		30.00
Spar, net ton		40.00
Silicon, gross ton		100.00
Manganese steel (12 per cent), net ton		30.00
Melting loss using tunings not rusted, 10 per cent		
Production of iron:		
1 shift, 6 tons		
2 shifts, 14 tons		
3 shifts, 22 tons		
Power consumption per ton:		
1 shift, 850		
2 shifts, 800		
3 shifts, 750		
Cost of operation one shift 8 hours		
Conversion cost:		
Power, 6 x 850 = 5,100 kw.-hr. @ 1.25c. kw.-hr.		$63.75
Materials:		
Electrodes, 6 x 15 = 90 lb. @ 24c.	$21.60	
Lime, 6 x 20 = 120 lb. @ 1.5c. lb.	1.80	
Spar, 6 x 15 = 90 @ 2c. lb.	1.80	
Coal, 200 x 6 = 1,200 lb. @ 0.75c. lb.	9.00	
Silicon, 6 x 50 = 300 lb. @ $100 ton	13.40	
Mn steel 6 x 50= 300 lb. @ 1.5c. lb.	4.50	48.90

Tools	9.00	
Water and miscellaneous	3.00	
		22.00
Total		$360.61
Conversion cost per ton, $360.61 ÷ 22		$16.40
Scrap cost, $10 ton plus 10 per cent for loss		11.00
Total cost per net ton of iron at the spout		$27.40

tions covering several months. The average analysis of the iron made was as follows: Silicon, 2.25; carbon, 3.50; manganese, 0.65; sulphur, 0.04; phosphorus, 0.15.

Many suggestions have been offered regarding the possibility of smelting iron ore with scrap in localities where ore was available and only a limited amount of scrap. In view of present power cost, high labor cost and the fluctuating market of pig iron, this proposition appears for the present entirely out of question, as the figures in Table III will show.

TABLE III—ESTIMATED COST OF PRODUCING GRAY IRON FROM TURNINGS, BORINGS AND IRON ORE (Hematite or Limonite)

For comparison with the preceding figures we will assume a furnace of 750-kw.-hr. electrical capacity, stationary furnace of the crucible type, with arch and charging doors under the arch.

Charge to produce 2 net tons pig iron:		
1.1 tons scrap		
2.2 tons ore high grade		
80 lb. lime		
30 lb. spar		
1,400 lb. coal		
100 lb. silicon		
100 lb. Mn scrap		
Power required for scrap per ton of iron produced, kw.-hr.		750
Power required per ton iron from ore, kw.-hr.		2,200
Power required to smelt one charge producing 2 tons iron, kw.-hr.		2,950
The furnace operating on 90 per cent load factor would consume 750 x 24 x 0.9 = 16,200 kw.-hr. per 24 hours		
The number of charges run in one day or 24 hours would be 16,200 ÷ 2,950 = 5.5 charges, or a daily production of 11 net tons iron		
Conversion cost:		
Power, 16,200 kw.-hr. @ 0.8c. kw.-hr.		$129.60
Materials:		
Electrodes, 220 lb. @ 24c. lb.	$52.80	
Lime, 440 lb. @ 1.5c.	6.60	
Spar, 165 lb. @ 2c. lb.	3.30	
Coal, 5.5 x 1,400 = 7,700 @ 0.75c.	57.75	
Silicon, 5.5 x 100 = 550 @ $100 ton	24.55	
Mn steel, 5.5 x 100 = 550 @ 1.5c. lb.	8.25	
Labor (see 3-shift operation)		42.00
Repairs and miscellaneous (see 3-shift operation)		22.00
Total		$346.85
Conversion cost per net ton, $346.85 ÷ 11		31.45
Scrap cost, 1.1 tons @ $10 ton ÷ 2		5.50
Ore cost, 2.2 tons @ $5 ton ÷ 2		5.50
Total cost of iron per net ton from ore and scrap based on 3-shift operation		$42.45

Under similar operating conditions we have an iron cost of $27.40 per net ton using all scrap, as against $42.45 using ore and scrap mixed. The greatly increased power required to smelt ore cuts down the output and brings up the cost.

If it is desired to produce pig iron with a higher silicon content, it is only necessary to add to the total cost the extra expense of the silicon, which runs about $2 additional for each 1 per cent. For convenience the figures given have been for net tons.

Furnace Construction Costs

The cost of furnace construction varies with different localities, but high and low figures are given for comparison.

The figures are based on 750-kw. stationary furnace, acid lined, three phase, three electrodes, hand operated. High tension voltage, 11,000; low tension side, 70 volts, sixty cycle. Three transformers, air-cooled type.

Furnace steel work	$700.00	$900.00
Transformers and freight	3,200.00	4,200.00
Furnace lining	400.00	700.00
Foundations	250.00	300.00
Plumbing	100.00	150.00
Electrical equipment and castings	1,000.00	1,500.00
Miscellaneous	300.00	500.00
Total	$5,959.00	$8,250.00

The higher figure would cover installations of this type in the West and includes all labor, but not engineering service. While this furnace gives very good results and is especially adapted for the production of pig iron, the so-called tilting furnaces are better adapted for general casting work in the foundry, and are almost universally used for this purpose.

Flake Graphite as a Lubricant

A study of flake graphite as a lubricant is being made by the Bureau of Mines. An interesting development in connection with the graphite work is that the lower grades can be purified by the Trent process, thus rendering them suitable for lubrication purposes.

The Relation Between the Composition of Vapor and Liquor in Distillation

An Experimental Study of Some of the Fundamental Laws Governing the Distillation of Mixtures, Including the Derivation of a Number of Formulas of Use in the Solution of Practical Problems Connected With the Design and Operation of Distillation Equipment

BY EMIL PIRON
President, Piron Coal Distillation Systems, Inc.

THERE are many in the chemical industries, especially among the younger members of operating and production departments, who are more or less unfamiliar with the basic laws of distillation. It is therefore the intention of the present paper to review some of these theoretical considerations and to show that they have an important bearing on practical problems confronting the operator, as well as the designer, of distillation apparatus.

If s is the proportion of one component in a mixture such as a gas liquor, and S the proportion of the same component in the vapor distilled from this liquor, the relation between the composition of the vapor and liquor in regard to the considered component is $k = \frac{S}{s}$

In industrial distillation, liquors are either concentrated or exhausted and in both cases the strength of the liquor passes through a number of stages of different concentration. Knowing the values of k corresponding to these different stages, we are in a better position to study the design of the distillation apparatus and to control its operation.

DETERMINING DISTILLATION CONSTANT EXPERIMENTALLY

One way in which the values of k can be obtained is to submit a relatively large quantity of liquor to distillation, taking very small fractions of the distillate, so that the composition of the liquor can be considered as constant during the distillation of each fraction. An analysis of the liquor and of the corresponding distillate will give corresponding values of s, S and k.

In Table I a distillation test on 1,000 c.c. of ammonia liquor, as obtained by coal distillation, is given as an example. It will be noted that the value of k varies with the strength of the liquor.

OBTAINING THIS VALUE BY CALCULATION

On the other hand, in distillation problems we need an ideal or average constant value of k, which, when applied to the problem, will give a result conforming to the actual. This ideal value of k can be found by the following method.

Suppose we distill out of a quantity Q of liquor, containing a proportion s of a component, an infinitesimal quantity dQ. The proportion of the same component in the distillate at the beginning of the distillation is S, at the end $S - dS$. The average strength of the distillate is $S - \frac{1}{2}dS$, while the quantity of the component we have in the distillate is $(S - \frac{1}{2}dS)\,dQ$.

During the distillation, the proportion of the component in the liquor changed from s to $(s - ds)$, the quantity remaining in the liquor after distillation being $(Q - dQ)\ (s - ds)$.

Hence the relation

$$Qs - (Q - dQ)\ (s - ds) = (S - \tfrac{1}{2}dS)\,dQ$$

which gives, after neglecting the differentials of the second order,

$$\frac{dQ}{Q} = \frac{ds}{S - s}$$

or, if the initial quantity of liquor was Q_o:

$$\log_e Q_o - \log_e Q = \int_{s_o}^{s} \frac{ds}{S - s}$$

If $\frac{S}{s} = k$ (constant), then

$$\log_e Q_o - \log_e Q = \frac{1}{k - 1}\,(\log_e s_o - \log_e s)$$

or

$$\left(\frac{Q_o}{Q}\right)^{k-1} = \frac{s_o}{s} \qquad (1)$$

which gives the desired value of k.

For instance, according to the distillation test given in Table I, we have

$$Q_o = 1{,}000 \qquad Q = 500$$
$$s_o = 7.72 \qquad s = 0.006$$

hence

$$\left(\frac{1{,}000}{500}\right)^{k-1} = \frac{7.720}{0.006}$$

$$k - 1 = \frac{\log_e 7.72 - \log_e 0.006}{\log_e 2} = 10.3$$

$$k = 11.3$$

This value of k, applied to distillation operations where the concentration of the ammonia liquor of the quality given above varies from 7.72 to 0.006 g. per liter, will give results corresponding with those actually obtained.

There are, however, instances in which it is not so easy to find the value of k—that is, cases where the pro-

TABLE I—DISTILLATION TEST ON 1,000 c.c. OF AMMONIA LIQUOR

Liquor in Distillation				Distillate			
Quantity, c.c.	Volatile Ammonia—g. Total	Volatile Ammonia—g. per Liter	Aver.	Quantity, c.c.	Ammonia—g. Total	Ammonia—g. per Liter	$S = -$
1,000	7.7200	7.7200					
				25	1.7660		
975	5.9540	6.1060	5.835	5	.4580	91.590	15.7
970	5.4960	5.5630		70	3.7110		
900	1.7850	1.9830	1.915	5	.1388	27.762	14.5
895	1.6462	1.8470		95	1.1727		
800	0.4735	.5920	.575	5	.0304	6.086	10.6
795	0.4431	.5570		95	.3056		
700	0.1375	.1950	.191	5	.0073	1.4625	7.6
695	0.1302	.1870		95	.0892		
600	0.0410	.0680	.066	5	.0030	.6120	9.3
595	0.0380	.0640		95	.0350		
500	0.0030	.0060					

There are, however, instances in which it is not so easy to find the value of k—that is, cases where the pro-

portion of the considered component cannot be readily determined by chemical analysis, as happens, for instance, with mixtures of components of the same organic group. In such cases the following method will often give fair results.

Laws Applicable to Mutually Soluble Mixtures

In industrial practice, such mixtures consist generally of components of one chemical group which dissolve perfectly one in the other and respond very nearly to the relation

$$a_{1\times 2} = \sqrt{a_1 \times a_2}$$

where $a_{1\times 2}$ represents the mutual attraction of the unlike, and a_1, a_2 the mutual attraction of the like molecules.

Under such conditions, the following general laws can be applied:

(1) The partial vapor pressure of each component equals the product of the vapor pressure p of the same component considered separately, multiplied by the molecular proportion m of the said component in the mixture.

(2) The vapor pressure P of the mixture equals the sum of the partial vapor pressures of the components:

$$P = p_1 m_1 + p_2 m_2 + \ldots$$

(3) The molecular proportion M of a component in the vapor is in ratio with the partial pressure pm of same component in the mixture:

$$\frac{M_1}{m_1 p_1} = \frac{M_2}{m_2 p_2} = \ldots \qquad (2)$$

These two relations give:

$$\frac{M_1}{m_1 p_1} = \frac{M_2}{m_2 p_2} = \ldots = \frac{M_1 + M_2 + \ldots}{m_1 p_1 + m_2 p_2 + \ldots} = \frac{1}{P} \qquad (3)$$

and consequently the relation k' between the molecular proportions of each component in the vapor and in the liquor is:

$$k' = \frac{M}{m} = \frac{p}{P}$$

in which p is the vapor pressure the investigated component (considered separately as a pure liquor) would have at the temperature of the mixture, and P the pressure under which the distillation is made.

If we consider the proportions in weight S and s of a component in the vapor and in the liquor respectively, we have further:

$$\frac{S_1}{M_1 \text{ mol}_1} = \frac{S_2}{M_2 \text{ mol}_2} = \ldots = \frac{1}{M_1 \text{ mol}_1 + M_2 \text{ mol}_2 + \ldots}$$

$$\frac{s_1}{m_1 \text{ mol}_1} = \frac{s_2}{m_2 \text{ mol}_2} = \ldots = \frac{1}{m_1 \text{ mol}_1 + m_2 \text{ mol}_2 + \ldots}$$

where "mol" represents the molecular weight of the component.

This introduced in the relation (2) gives:

$$\frac{S_1}{p_1 s_1} = \frac{S_2}{p_2 s_2} = \ldots = \frac{1}{p_1 s_1 + p_2 s_2 + \ldots}$$

and

$$k = \frac{S}{s} = \frac{p}{p_1 s_1 + p_2 s_2 + \ldots}$$

But the use of this relation is not as easy as that of the relation (3), because $p_1 s_1 + p_2 s_2 + \ldots$ is not equal to the pressure P and must be calculated whenever the proportion of the components in the liquor is altered.

When we go further into the question, we see that the knowledge of k' given by the expression

$$k' = \frac{p}{P}$$

presupposes the knowledge of p (the vapor pressure of the pure component at the temperature of distillation of the mixture) with a degree of exactness we cannot find, in general, through the information we have available concerning vapor pressures.

Compensating for Differences in Vapor Pressure

For instance, for benzene, we find, according to different authors, vapor pressures varying as follows:

Temperature, Deg. C.	Vapor Pressure, Mm. of Hg
50	272.1 to 268.9
60	393.0 to 380.5
70	554.2 to 548.2
80	756 to 755
90	1,018 to 1,016
100	1,335 to 1,344
110	1,740 to 1,748

If we take the pressures shown in the third column and given by the Bureau of Longitudes of Paris,[1] as being the more correct, we still find considerable divergence from the calculated values. First, we note that the pressure 380.5 mm. should be 389.5 mm. Then, making the differences between this pressure and that of the vapor pressure at 50 deg. the first difference, and making the second difference the spread between the first differences, and then continuing the process to the third difference, we obtain the following values:

Vapor Pressures Mm. of Hg	First Difference	Second Difference	Third Difference
268.9			
	120.6		
389.5		38.1	
	158.7		10
548.2		48.1	
	206.8		6.1
755		54.2	
	261		12.8
1,016		67	
	328		9
1,344		76	
	494		
1,748			

As vapor pressure increases according to natural laws, it is evident that the third difference should vary uniformly, at least as long as no disturbing phenomena are met. The reason it does not vary uniformly is that the indicated pressures are not absolutely correct, but are located sometimes above, sometimes below, the real curve of pressures. We must therefore try to locate a uniform and more correct curve between these pressures. Values for such a curve can be obtained empirically after a few trials, and we derive the following table:

Temperature, Deg. C.	Corrected Pressure, Mm. of Hg	First Difference	Second Difference	Third Difference
50	268.9			
		120.6		
60	389.5		38.5	
		159.1		8.8
70	548.6		47.3	
		216.4		8.8
80	755		56.1	
		262.5		8.8
90	1,017.5		64.9	
		327.4		8.8
100	1,344.9		73.7	
		401.1		
110	1,746			

These values appear to correspond very closely to the reality.

Within the small range of temperatures used in distillation and using a constant third difference as a basis we can derive an expression which will give us a scale of temperatures sufficiently accurate for most purposes.

This is not absolutely general, but the practical results obtained by this method are more accurate than any other results based on experience.

[1] Annuaire du bureau des longitudes de Paris. Données physiques.

This scale of pressures is constructed as follows:

Third Difference	Second Difference	First Difference	Vapor Pressure a	Row 1
		b		
	c—		$a + b$	2
d		$b + c$		
	$c + d$		$a + 2b + c$	3
d		$b + 2c + d$		
	$c + 2d$		$a + 3b + 3c + d$	4
d		$b + 3c + 3d$		
	$c + 3d$		$a + 4b + 6c + 4d$	5
		$b + 4c + 6d$		
			$a + 5b + 10c + 10d$	6

where the expression of the pressure is given by the following equation:

$$p = a + b\frac{n-1}{1} + c\frac{n-1}{1}\times\frac{n-2}{2} + d\frac{n-1}{1}\times\frac{n-2}{2}\times\frac{n-3}{3} + \ldots.$$

This equation, when applied to the table already given for the vapor pressures of benzene, would give

$$n = \frac{t-40}{10}$$

$$p = 268.9 + 120.6\frac{t-50}{10} + \frac{38.5}{2}\times\frac{t-50}{10}\times\frac{t-60}{10} + \frac{8.8}{6}\times\frac{t-50}{10}\times\frac{t-60}{10}\times\frac{t-70}{10}$$

or

$$p = -64.6 + 6.58t - 0.9715t^2 + 0.001466t^3$$

But the use of this equation is difficult and it would be more convenient to have a table of pressures varying from degree to degree. In order to prepare such a table, we can make use of the quantities A, B, C, D, calculated from the equations:

$$D = \frac{d}{1{,}000};\ C = \frac{c - 900D}{100};\ B = \frac{b - 45C - 120D}{10};\ A = a$$

Applying these to the data for benzene, we obtain:

$$A = 268.9$$
$$B = 10.5783$$
$$C = 0.3058$$
$$D = 0.0088$$

and vapor pressures as shown in Table II.

TABLE II—CORRECTED VAPOR PRESSURES FOR BENZENE AND TOLUENE

Benzene Temp., Deg. C.	Toluene Vapor Pressure, Mm. of Hg	Toluene Pressure Difference per Deg. C.	Toluene Temp., Deg. C.	Benzene Temp., Deg. C.	Benzene Pressure Difference per Deg. C.	Benzene Vapor Pressure, Mm. of Hg
50	268.9		77.6	80		755.0
51	279.5	9.8	78.7	81	23.6	778.6
52	290.4	10.0	79.8	82	24.1	802.7

68	513.3	15.6	97.2	98	34.5	1,273.8
69	530.7	16.0	98.2	99	35.2	1,309.0
70	548.6	16.5	99.3	100	35.9	1,344.9
71	567.0	16.9	100.4	101	36.6	1,381.5
72	585.8	17.3	101.5	102	37.4	1,418.9
73	605.2	17.8	102.6	103	38.2	1,457.1
74	625.0	18.2	103.7	104	38.9	1,496.0
75	645.3	18.7	104.8	105	39.7	1,537.5
76	666.2	19.2	105.8	106	40.5	1,576.2
77	687.6	19.7	106.9	107	41.2	1,617.4
78	709.5	20.2	108.0	108	42.1	1,659.5
79	732.0	20.7	109.1	109	42.8	1,702.3
80	755.0	21.2	110.2	110	43.7	1,746.0

Knowing the vapor pressures of benzene, we can readily find the temperatures at which the other members of the benzene group have the same vapor pressure, by applying the law of proportion of absolute temperatures at equal pressures:

$$\frac{T_1}{T_2} = \frac{T'_1}{T'_2}$$

For instance, we have at a pressure of 760 mm. of mercury:

Boiling point of toluene.... 110.4 deg. C.
Boiling point of benzene.... 80.2 deg. C.

$$\frac{T_{tol}}{T_{ben}} = \frac{273 + 110.4}{273 + 80.2} = 1.0855$$

which will give the corresponding temperatures for toluene as indicated in Table II.

Once we have derived, by this method or any other, a sufficiently complete and correct table of the vapor pressures of the components, we can easily find the values of

$$k' = \frac{p}{P}$$

We have, for instance, for benzene and toluene in mixture boiling at the following temperatures, under a pressure of 760 mm. of mercury:

Temperature, Deg. C.	Benzene	Toluene
80.2	$k' = 1.000$	$k'_2 = 0.385$
81.8	1.050	0.409
83.7	1.112	0.438
85.75	1.182	0.478
88.1	1.267	0.506
90.75	1.368	0.553
93.8	1.492	0.608
97.2	1.640	0.677
101.0	1.818	0.758
105.3	2.036	0.863
110.4	2.320	1.000

In this case, as with ammonia liquor and almost any other mixture, k is variable. Sometimes, however, we are able to find an ideal constant value of k as was done for ammonia liquor, by a similar method. Knowing the composition of the final liquor we want to obtain, we find its boiling temperature with the help of our tables of vapor pressures. Then we can make a distillation test on the original liquor and note the quantity of residue that is left, when the temperature reaches the boiling temperature of the final liquor. With this value Q, and the composition of the original and final liquor s_0 and s, equation (1) will give the average value of k.

More often, however, such a distillation test will not give us any definite result. The purpose of industrial distillation, in general, is to separate almost pure products out of a mixture, and when we distill a sample of the mixture in the laboratory the whole liquor often distills over before the temperature reaches that of the component supposed to remain as residue. The reason is that for these mixtures the value of k is too near to unity and the evacuation of the more volatile components proceeds so slowly that only a quantity of residue, too small to be estimated, remains in the flask. But for liquors distilling according to the laws previously mentioned, if we cannot find the ideal constant value of k by experience, we can calculate it.

We have seen before that

$$\log_e Q_0 - \log_e Q = \int_{s_0}^{s}\frac{ds}{S - s}$$

The values of this integral if determined graphically are the surfaces located between the x-axis, the curve $y = \frac{1}{S - s}$ and the values of s_0 and s. Suppose this value is N and we have

$$\log_e Q_o - \log_e Q = N$$

which, combined with equation (1), gives

$$k = 1 + \frac{\log_e s_o - \log_e s}{N}$$

This value of k will then take the place of its variable values in our distillation problems.

Application to Distillation Problems

For instance, we take a mixture containing 80 per cent of benzene and 20 per cent of toluene from which we wish to extract the benzene until only 0.5 per cent is left in the residue of toluene. Suppose these percentages are molecular proportions for which we have to use the expression $\frac{1}{M - m}$ instead of $\frac{1}{S - s}$. We calculate first, with our tables of pressures, the values of M and $\frac{1}{M - m}$ for different values of m, in order to construct the curve $y = \frac{1}{M - m}$ with sufficient exactness between the values $m_o = 0.8$ and $m = 0.905$.

We find, for instance, that the mixture of 80 per cent benzene and 20 per cent toluene under a pressure of 760 mm. of mercury boils at 84.45 deg. C., since at this temperature

$$p_1 m_1 + p_2 m_2 = 692 + 68 = 760$$

and further, that

$$M = \frac{mp}{P} = \frac{692}{760} = 0.91$$

which, combined with $m = 0.8$, gives

$$\frac{1}{M - m} = \frac{1}{0.11} = 9.091$$

The following table and diagram (Fig. 1) are based on this calculation:

m	M	$\frac{1}{M-m}$	m	M	$\frac{1}{M-m}$
0.80	0.91	9.091	0.20	0.374	5.763
0.70	0.854	6.506	0.10	0.2072	9.328
0.60	0.789	5.277	0.06	0.1300	14.286
0.50	0.711	4.737	0.04	0.08873	20.500
0.40	0.620	4.553	0.02	0.04530	39.516
0.30	0.508	4.805	0.01	0.022974	77.077
			0.005	0.011545	152.790

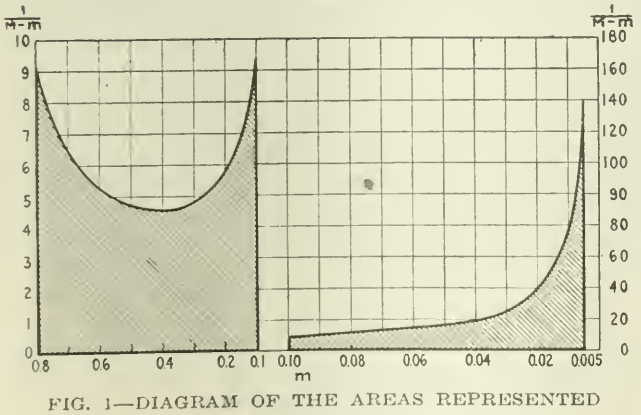

FIG. 1—DIAGRAM OF THE AREAS REPRESENTED BY $\int_{m_o}^{m} \frac{dm}{M-m}$

The area between the curve, the x-axis, the extreme values of m is $N = 6.52$, which gives

$$k = 1 + \frac{1}{6.52} \log_e \frac{0.8}{0.005} = 1.778$$

This represents, therefore, the relation between the composition of vapor and liquor for benzene distilled out of mixtures of benzene and toluene during the distillation of which the concentration of benzene in the liquor passes from 80 per cent to 0.5 per cent.

It is interesting to verify the correctness of the calculated results as compared with those obtained experimentally. During the war, considerable attention was paid to mixtures of benzene and toluene. In an article[2] which appeared in 1916 in the *Journal of the Society of Chemical Industry* are given the boiling points of such mixtures containing the proportion of benzene indicated in the second column of following table. The third column gives the composition calculated according to the method previously discussed:

Temperature, Deg. C.	Percentage of Benzene in Mixture. Observed	Calculated
81.8	90	90.98
83.7	80	80.96
85.75	70	71.17
88.1	60	61.06
90.75	50	50.74
93.8	40	40.30
97.2	30	30.07
101.0	20	20.04
105.3	10	10.08

As will be observed, the differences are small enough to be neglected in ordinary distillation practice. The laws we have utilized to arrive at this result can also be applied to the distillation of other mixtures of the aromatic hydrocarbons as well as those of the paraffin series. It will be noted that the method is to be applied to a chosen component, independently of, and disregarding other components in the mixture.

Ceramic Imports and Exports of Belgium

Commerce Reports for Jan. 16, 1922, summarizes the foreign trade of Belgium in ceramics.

Reviving trade with Germany was one of the outstanding features of Belgium's 1921 imports of ceramic products. Of the ten classes of pottery imports shown in Belgian official statistics, Germany was the chief source for six, France for three and the Netherlands for one. In glassware out of twelve items Germany led in ten and France in two.

Belgium is, however, a much larger exporter than importer of ceramics, its sheet and plate glass having a world-wide reputation for quality and even its more bulky pottery products finding markets in South America and other distant fields. The latest available figures relating to Belgium's foreign trade in ceramic products are those covering the first nine months of 1921. These, with corresponding 1920 data for comparison, are summarized below:

	Imports		Exports and Re-exports.	
Pottery	Jan.-Sept., 1920, Kilos	Jan.-Sept., 1921, Kilos	Jan.-Sept., 1920, Kilos	Jan.-Sept., 1921, Kilos
Earthenware, fine (except tiles)	2,592,890	3,405,721	1,735,355	1,668,371
Chinaware (except tiles)	668,743	1,065,216	77,798	171,818
Terra cotta:				
Bricks, drainage pipes, etc.	41,806,517	75,171,989	342,779,715	598,509,249
Tiles—				
Varnished or enameled, and tongued-and-grooved	2,178,970	4,582,965	21,464,157	28,702,901
Other	2,000,537	531,115	16,310,140	19,232,390
Paving and building blocks and tiles:				
Of earthen or stoneware	443,343	272,783	16,400,408	11,108,272
Of concrete	225,307	75,396	14,399,797	11,921,717
Of fine earthenware or china	132,385	184,940	4,490,460	3,241,376
Not specified	166,121	451,350	5,936,398	1,626,787
Common pottery	1,758,432	1,892,900	4,481,400	1,876,553
Total quantity	51,973,245	87,634,375	428,075,628	678,059,464
	Francs.	*Francs.*	*Francs.*	*Francs.*
Total value	24,619,360	27,947,507	53,011,314	63,523,762

Production of Shrunk Coke in Electrode Manufacture

By J. L. McK. Yardley
General Engineer, Westinghouse Electric & Manufacturing Co.

CARBON and graphitized electrodes are made from retort carbon, petroleum coke or anthracite coal. Petroleum coke is probably the most desirable material for this purpose, since it consists of from 90 to 95 per cent of fixed carbon of from only 5 to 10 per cent of volatile matter, and has less than 1 per cent of either sulphur or ash. In addition, it is easily obtainable in quantity. It has been quoted recently at $12 to $13 per net ton at the refinery Atlantic seaboard. It is the final product in the dry or cracking distillation of paraffine base petroleum and is obtained by the destructive distillation of the tar. The yield is about 10 per cent of the tar or 1 per cent of the petroleum dry distilled. It is particularly desirable to have this material as the principal constituent of electrodes which are to be used in furnaces or in electrolytic processes, into which the least possible amount of silicon impurity should be introduced.

The manufacture of electrodes must meet most exacting requirements from the various industries in

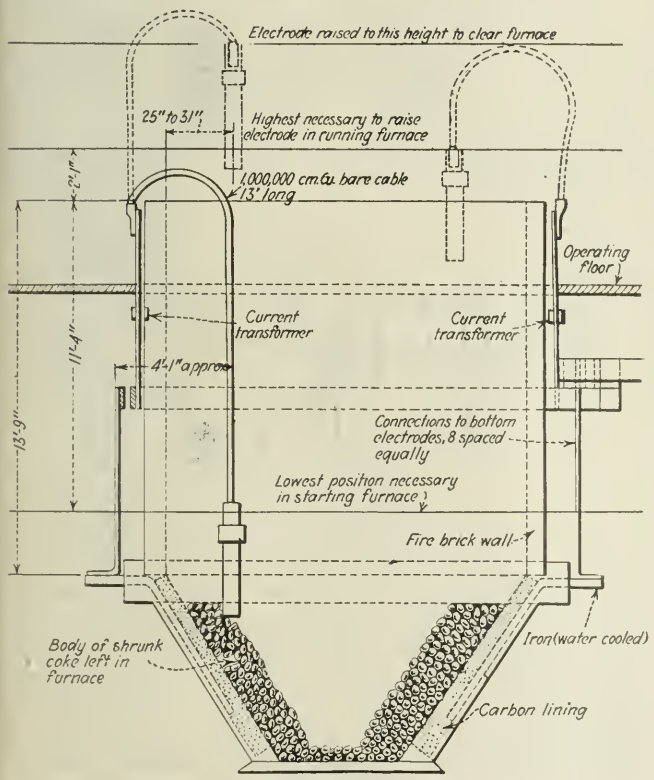

FIG. 1—CALCINING FURNACE, TOP AND BOTTOM ELECTRODE TYPE

which they are employed, and success is dependent upon attention to particulars in the various departments, such as

1. Selection of materials.
2. Calcination of materials.
3. Grading and mixing of materials.
4. Extrusion of homogeneous green electrodes under pressures up to 600 tons.
5. Gradual and uniform baking to an ultimate temperature in the neighborhood of 1,400 deg. C.
6. (Where desired) Graphitizing of baked electrodes in an electric furnace at a temperature above 2,000 deg. C.

These steps in the process of manufacture are all

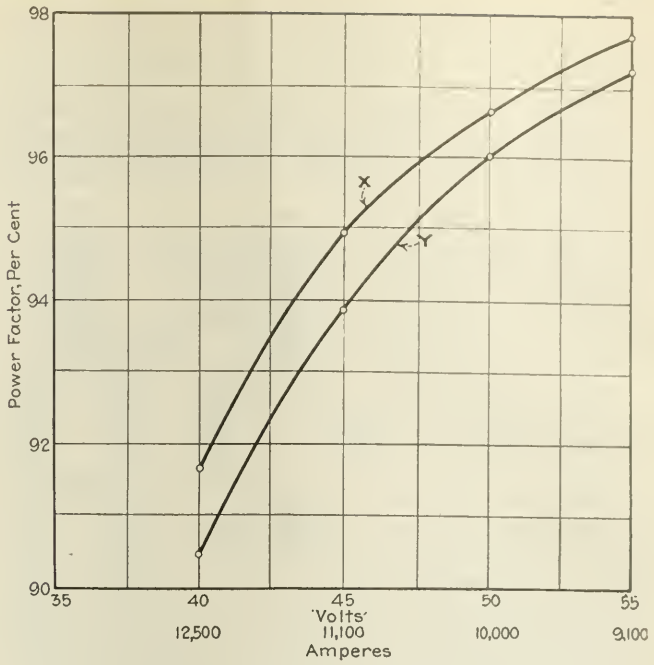

FIG. 2—POWER FACTOR OF 500 KVA. CALCINING FURNACE. SINGLE PHASE, 25 CYCLE

important and interesting, particularly the baking of the electrodes. This is carried out in a large number of producer gas-fired furnaces or pits of ingenious construction and arranged so as to give a high thermal efficiency. In recent installations the calcining of materials is carried on in the electric furnace. Since the raw materials contain considerable volatile constituents, these must be driven off in the calcining operation to form what is called shrunk coke.

Calcining is performed in an open top, single-phase electric furnace of either the two-top electrode type or the top and bottom electrode type. Usual capacity for the former is 500 kva., and around 1,000 kva. for the latter type. Power is applied approximately 24 hours, or until a certain kw.-hr. energy has been expended as pre-established for the material charged. The furnace is left idle to cool for the next day, and on the following day it is emptied and made ready for the next heat. Therefore three furnaces of the present type are required for a cycle for continuous operating, giving an output of about 25 tons a day.

The 1,000-kva. top and bottom electrode type furnace itself consists of a cylindrically shaped steel shell, about 13 ft. in diameter and 14 ft. high. A brass strip is inserted to prevent a complete magnetic circuit. The cylindrical walls are lined with firebrick. The bottom, which may be flat or shaped like an inverted truncated cone, is also lined with firebrick, over which a high-grade dry carbon lining is placed and over this is placed a thin layer of sheet metal to prevent the tar from the petroleum coke from soaking into the lining and ruining it. Eight iron bars are laid in the carbon lining projecting radially toward the center. The bars and the carbon lining constitute one set of electrodes, the current being carried from them by copper connectors to the busbars, which encircle and are supported by the steel shell. The other set of electrodes consists of eight carbons about 7 in. in diameter and 4 ft. long, which are cast about an iron bar approximately 1 x 6 in. in section and 4 ft. long. These bars are attached to flexible copper cables 13 ft.

long. The upper electrodes are adjusted manually by means of winches. A furnace of this type is shown in Fig. 1.

Having had occasion to make a rather thorough investigation of this operation several years ago with my associates, it is proposed to describe an electrical installation which was developed to meet the difficult conditions involved. The conditions are difficult, particularly with 60-cycle power supply, owing to the heavy currents at low voltages which are employed. The particular ends to be attained in addition to high over-all efficiency, are high over-all power factor and uniform division of current between electrodes where there are a number in parallel, so as to produce a uniform heating effect and also ease in operation, and between the parallel secondary supply circuits to the electrodes. As an example of the care with which such furnace installations should be designed, Figs. 2 and 3 are supplied, showing the results of an analysis of two proposed lead arrangements for a number of 500-kva., single-phase, two-top electrode type calcining furnaces. In this case, the rate at which power would be paid for, as well as the amount of power into the furnace, was dependent upon the power factor, and although the supply was at 25 cycles, extra precautions in design were deemed necessary. In Fig. 2, curve *X*, as compared with curve *Y*, shows the calculated improvement in power factor obtained by interlacing the copper bars for the 6-ft. run according to diagram *X*, Fig. 3, as compared to the non-interlaced arrangement shown in diagram *Y*, Fig. 3.

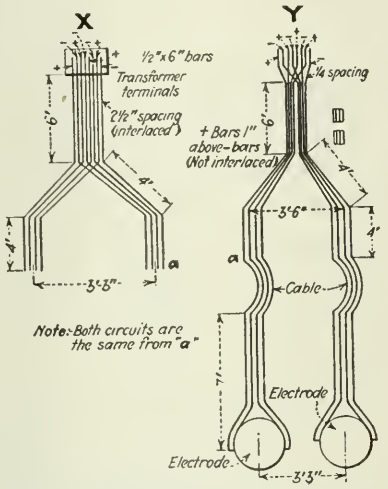

FIG. 3. METHODS OF CONNECTING LEADS
X = 6-ft. run leads interlaced.
Y = 6-ft. run leads non-interlaced

Referring to the installation layout shown in Fig. 4 in order to have an output of 50 or 60 tons per day, it was proposed to operate a total of six furnaces similar to the one described. The furnaces would be arranged in two groups of three each. By converting from the three-phase transmission voltage to two-phase furnace voltage, the two furnaces taking power each day would form a practically balanced load upon the power system. Power would be cut off from the other furnaces by lifting up and disconnecting their movable electrodes. Each furnace taking power would receive its current through eight movable electrodes and eight corresponding fixed electrodes. There would be eight separate circuits back to the transformer, each capable of being independently adjusted to give the desired amount of current and each tending, on account of its own impedance, more readily to give that current. The principal equipment proposed for this installation includes:

Two 1,250-kva., single-phase, 60-cycle, maximum rated stepdown transformers, Scott connected for three-phase, 13,200 volt high tension, two-phase 2,200 volt low tension and provided with full capacity taps to give 2,310. 2,420, 2,530 and 2,640 volts low tension. Two 1,200-kva., single-phase, 60-cycle, maximum rated furnace transformers, with 2,640 volt high-tension and low-tension voltages 48, 54, 60, 66, 72 and 84 at full capacity, and 42 at reduced capacity. When operated at 2,200 volts high tension, these transformers designed to give low-tension voltages from 35 to 70 in 5-volt steps.

The operation of the furnace is as follows:

One electrode is lowered to the bottom of the furnace and an arc is set up. The petroleum coke is placed around that arc until current will flow through it. Then an arc is started at a second electrode in similar manner, and this process is continued until all electrodes are in operation. The furnace is then loaded and the electrodes are raised as rapidly as possible, while still maintaining a condition of having considerable current flowing through them. Finally the furnace is practically full and the electrodes are in their upper position imbedded in the coke. Except at starting, the heating of the mass is entirely through the resistance of the material itself.

The average total power consumption of this plant would be in the neighborhood of 900 kw.-hr. per ton

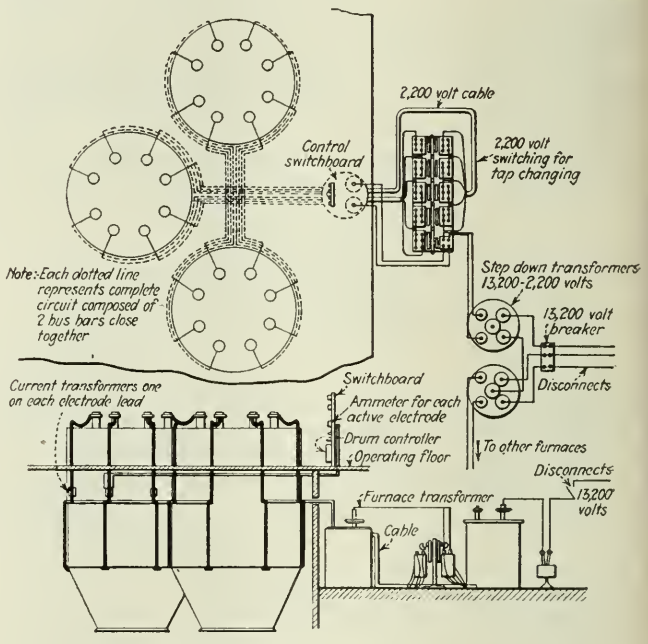

FIG. 4—INSTALLATION OF CALCINING FURNACE

of shrunk coke, and at a power factor above 90 per cent. The demand for electrodes in the electric steel and ferro-alloy industries and in the electrolytic chlorine industry, as well as in the aluminum industry, where approximately ⅔ to ¾ lb. of electrodes is required for each pound of aluminum produced, is great enough to demand the output of several such calcining plants in the manufacture of electrode carbon and graphite.

Panama Canal to Sell Surplus Supplies

The Panama Canal is about to offer for sale a large quantity of surplus material now in stock on the Isthmus, including manila rope, copper screening, nails, glass, paints, lubricating oils and greases, millwork, chemical materials, hose, chain, pig iron, non-ferrous metals, burlap, canvas, foundry supplies and numerous other commodities.

Interested parties should communicate with the General Purchasing Officer, the Panama Canal, Washington, D. C., for detailed information as to the material available for sale, terms of sale, etc.

Synopsis of Recent Chemical & Metallurgical Literature

Bond Clay Mixtures for Glass Pots.—D. H. Fuller, of the U. S. Bureau of Standards, has made some studies to determine whether as good results can be obtained from mixtures of American clays as from the Gross Almerode clay in glass pot bodies and reported in the *Journal* of the American Ceramic Society for November. Two American ball clays were combined in various proportions with two siliceous American bond clays and compared with the Gloss Almerode clay in bodies containing 50 per cent grog. Physical properties and resistance to glass batch corrosion were determined. It was not found possible to duplicate the physical properties, especially the low water of plasticity and low drying shrinkage of the Gross Almerode body, but several of the bodies gave better results as regards resistance to corrosion than the one containing the Gross Almerode clay. In general it was concluded that it is possible by blending American clays to produce a body equal or superior to the Gross Almerode body. More thorough heat-treatment of pots or tank blocks in the arches and greater uniformity in temperature during the burning is required.

On the Distribution of Temperature in Steel Ingots During Cooling.—Seizô Saitô, the author of this paper appearing in the 52nd report from the Japanese Iron and Steel Research Institute (*Science Reports*, vol. 10, No. 4, Sept. 1921), aware of the complexity of the mathematics that accompanies the consideration of octagonal and hexagonal shapes, deals only with cylindrical and square molds. The heat of

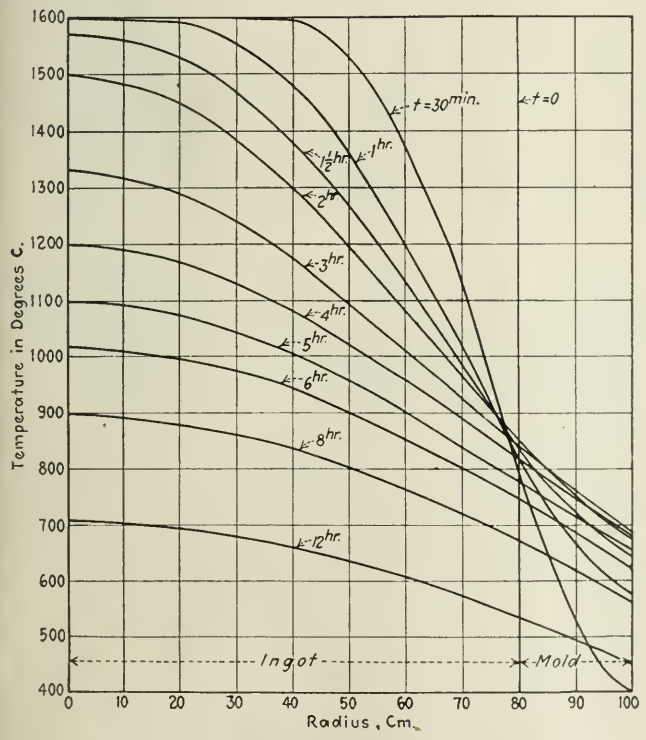

FIG. 1—TEMPERATURE-DEPTH CURVES AT VARIOUS TIME INTERVALS AFTER POURING

solidification is also omitted, hence the calculations apply to cooling below the solidification point. The initial temperature of the melt is supposed to be 1,600 deg. C., and that of the mold is 0 deg. C., and it is assumed that there is no convection of heat and that the constants have the same value both in the liquid and solid states. The complex derivations of the mathematical formulas cannot be abstracted, but the plotted diagrams obtained from the numerical values are reproduced as far as they are of interest.

The numerical data on heat conduction obtained for a cylindrical ingot of infinite length disclose the distribution of temperature in the ingot and the mold after different lapses of time; also the variation of temperature at different distances from the center for definite time intervals are given.

In Fig. 1 there is shown the manner in which the isothermals fall from the center toward the surface of the mold in an ingot 160 cm. (5 ft. 3 in.) in diameter—that is, corresponding to about a 60-ton ingot. This graph also shows the magnitude of the temperature gradient in the inner portions, which coincides with the known rules of solidification and which is visible in an etching of the cross-section as a segregation ring.

Fig. 2 discloses the fact that with the exception of points near the inner surface of the molds the temperature at a

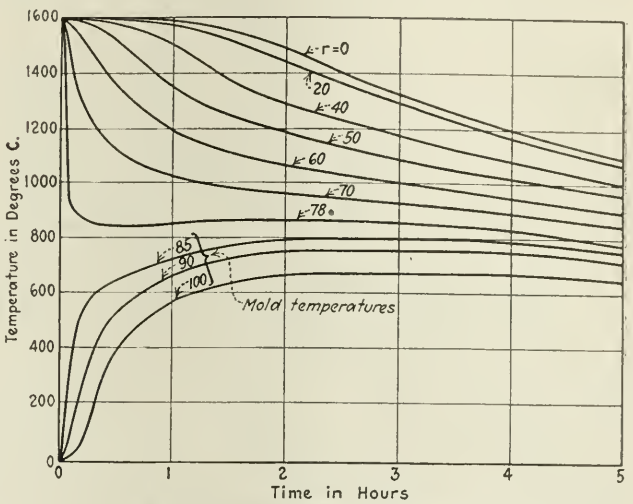

FIG. 2—TEMPERATURE-TIME CURVES FOR VARIOUS POSITIONS IN INGOT AND MOLD

given point falls continuously as time goes on, but that at points near the mold the temperature falls rapidly at first and then increases as the time elapses, after which a gradual cooling proceeds in the usual way. The temperature of the mold increases rapidly at first and after reaching a maximum gradually decreases with time. In other words, the mold and the ingot equalize and after equalizing both appear to cool as a unit. In fact, this is only a mathematical result which supports the actual facts of everyday practice. Since in practice the weight of a mold is equal to the weight of the ingot, the temperature reached by the mold will be approximately half the temperature of the ingot.

Fig. 3 represents an actual experiment with a melt that has been cast in a mold of an outer radius of 40 cm. and inner radus of 27 cm. of 180 cm. mold length, the tempera-

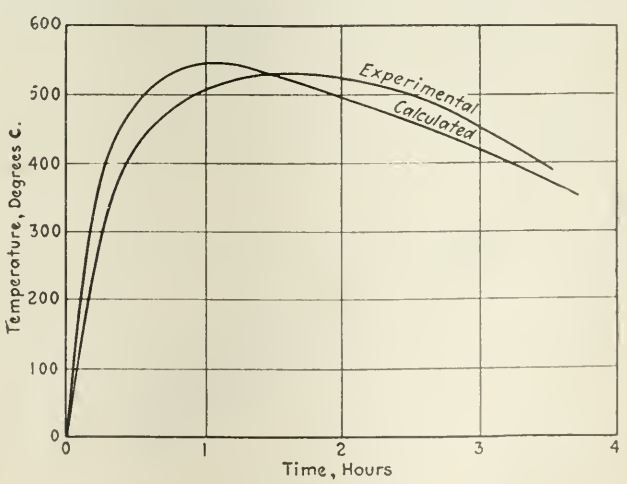

FIG. 3—COMPARISON OF CALCULATED AND OBSERVED TEMPERATURES OF OUTSIDE OF INGOT MOLD

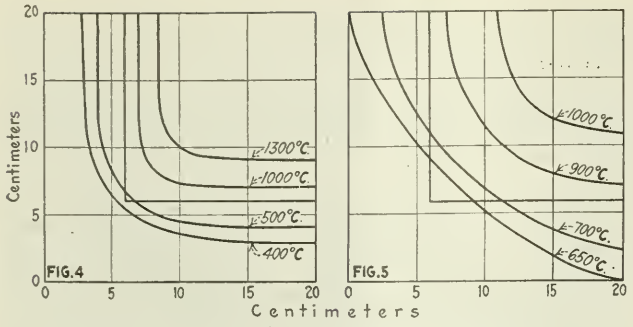

FIGS. 4 AND 5

Fig. 4—Isothermals in square ingot after 1 minute.
Fig. 5—Isothermals in square ingot after 5 minutes.

ture of the melt being 1,500 deg. C. The temperature of the outer surface of the mold at midheight as measured coincides closely with the calculated result.

There is also a numerical calculation given for a case which assumes that the mold is kept at 0 deg. This case is of no practical value. However, it points out that after 12 hours the temperature at the center of the cylinder is only 200 deg. C., a temperature considerably lower than that in the former case after the same lapse of time (710 deg. C., from Fig. 1). A plot similar to Fig. 2 shows that in the inner portion of the cylinder the rate of the temperature fall with increasing radius is very small and its gradient almost the same as with an uncooled mold. Hence we may conclude that in the case of such a large ingot, although the outer surface of the mold is rapidly cooled by some special means, segregation cannot be prevented, and the diameter of the segregation ring also remains almost unaffected.

An infinitely long prism with a section 68 cm. square (2 ft. 3 in.) was calculated. Figs. 4 and 5 show the calculated and plotted curves, with the characteristic that the isothermal lines round off the corners of the square.

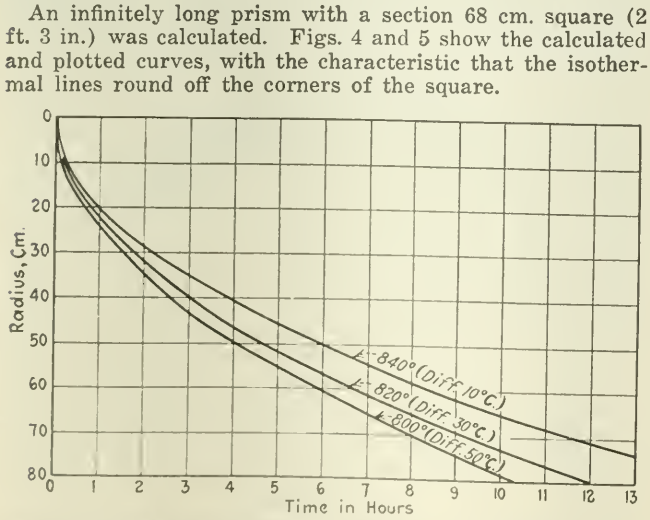

FIG. 10—TIME REQUIRED TO REACH TEMPERATURE AT THE CENTER OF INGOTS OF VARIOUS SIZES

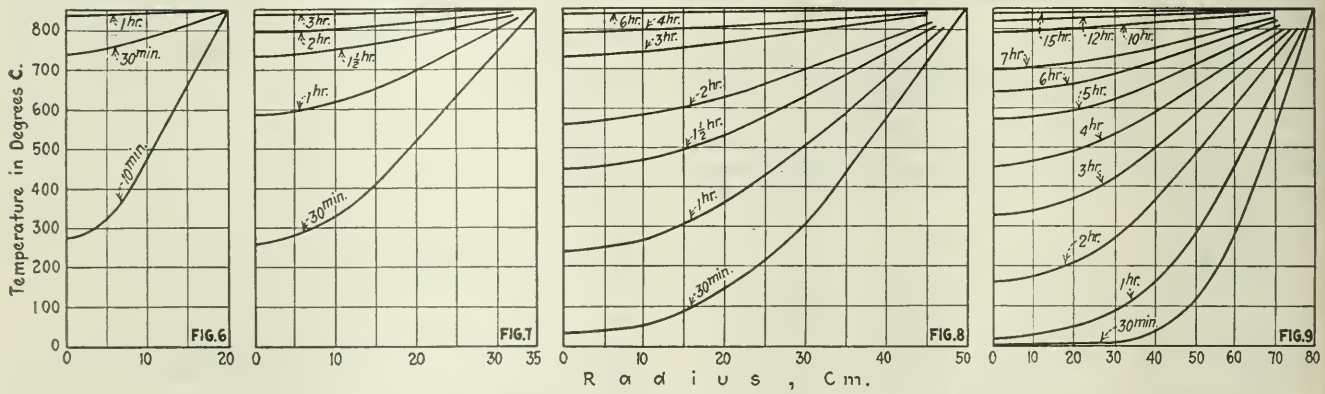
Thermal stress in a steel ingot in which the temperature distribution is not uniform has already been solved by Lorenz, in his "Technische Elastizitäts Lehre," and Saitô's calculations follow his method.

A problem of practical importance dealt with is that of annealing large ingots or thick plates. A mathematical solution of this is already well known, but the author states that the data at hand are not trustworthy.

It is assumed that the cylinder in the mathematical problem is initially at 0 deg. C., and its surface is always kept at 850 deg. C. The calculations show the distribution of temperature at different time intervals for the radii 20 cm., 35 cm., 50 cm. and 80 cm., and the results are given in Figs. 6, 7, 8 and 9. Calculated results are also given for the temperature at axis of each cylinder corresponding to different time intervals. The time required for obtaining 800 deg. C., 820 deg. C. and 840 deg. C. at the axes of various cylinders are shown in Fig. 10, assuming a constant skin temperature of 850 deg. C. The curves resemble parabolas.

When computing data on the cooling of heated cylinders or plates, the surrounding temperature is assumed to be kept at zero and the temperature distribution is just the reverse of the above. In practice, however, the boundary conditions are not the same as those required in the assumed theory. In actual heating the outer surface will acquire the heat by radiation and hence it will require a much longer time than that expected from the theory. Verification of this fact is given by E. F. Law, *Journal*



FIGS. 6 TO 9—TEMPERATURE-DEPTH CURVES AFTER VARIOUS HEATING PERIODS

Fig. 6—40-cm. cylinder. Fig. 7—70-cm. cylinder. Fig. 8—100-cm. cylinder. Fig. 9—160-cm. cylinder.

Iron and Steel Institute, No. 1, 1918. In his experiment Law shows that the interval of time required to heat the center of a steel cube from ordinary temperature to 900 deg. C. is considerably greater than that required for the center to cool from 900 deg. C. to room temperature.

The author also deals with the cooling of a thick plate or cylinder of infinite length, the heat of transformation of which is taken into account.

Titanium Alloys.—M. A. Hunter and J. W. Bacon (Rensselaer Polytechnic Institute, Engineering and Science Series, No. 12) have investigated the electrical properties of various alloys of pure metallic titanium, reduced by sodium. If 0.5 per cent is added to commercial Norway iron and melted in an Arsem furnace, all but a trace of titanium is lost, but the resulting metal exhibited improved magnetization and hysteresis curves. Larger additions were not beneficial. Pure titanium, forged into a rod at red heat, possesses a high specific resistance — 88 microhm-cm. — but when alloyed with various alloys of nickel, copper and iron, produced wires of only moderately high resistance. It is exceedingly hard to draw such alloys containing more than 5 per cent titanium.

Terra Cotta Casting.—Technology in the manufacture of terra cotta has become an accomplished fact. R. F. Geller of the U. S. Bureau of Standards published a paper in the November issue of the *Journal* of the American Ceramic Society on possibilities of terra cotta casting. The experimental methods described therein involved the treatment of clays and bodies with varying amounts of salts and cast in the form of small ashlars. The casting properties, vis-

cosity, specific gravity and drying behavior of three kaolins, two ball clays, one fireclay and four representative commercial bodies, together with terra cotta clays, were studied. The author concluded that kaolins have an open structure, but do not develop strength on drying. Bonding properties are furnished by ball clays, which, however, tend to seal against the mold. Commercial terra cotta bodies tested do not possess good casting properties, but can be modified through a study of the component clays. Mechanical difficulties attending the casting of terra cotta render the feasibility of the process doubtful at the present time.

Recent Chemical & Metallurgical Patents

British Patents

For complete specifications of any British patent apply to the Superintendent, British Patent Office, Southampton Buildings, Chancery Lane, London, England.

Crystallizing.—Granular crystals—for example, of sodium chloride—are obtained from solutions by supersaturating a solution out of contact with crystals by evaporation or by cooling, and circulating the supersaturated solution through a mass of crystals which are caused to grow. The agitation of the mass of crystals may cause the formation of spherical granules. The solution drawn from an evaporating chamber *b*, Fig. 1, is forced by a pump *g* through a superheater *a* and pipe *i* back to the evaporating chamber. Evaporation takes place at the upper surface *o* and the supersaturated solution is drawn upwards through an inner chamber *e* containing a mass of crystals. When the crystals have attained a certain size they fall against the flow

FIG.1.

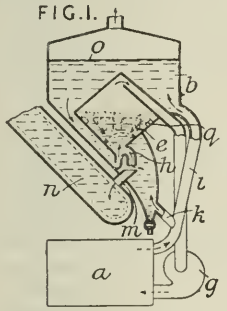


FIG.2.

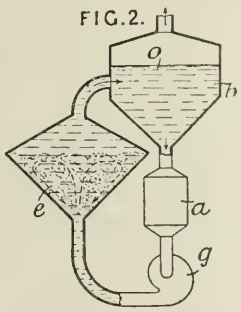

of the liquid into the base of the vessel *e* and are discharged through an opening *h* and through a pipe *m* to an elevator *n*. Curved baffles *q* inside the vessel *e* cause all parts of the crystal mass to pass over the opening *h*. When the solubility of the substance does not increase rapidly with the temperature, the solution may be passed through the superheater *a*, Fig. 2, directly into the crystallizing vessel *e* and thence into the evaporating vessel *b*. To prevent fine crystals being carried from the crystallizing vessel, fresh solution may be fed by a jet discharging into an open coiled pipe or chamber in the upper part of the vessel *e*. Alternatively, the small crystals may be removed from the circulating current of solution by filtration, centrifugal treatment or by settling, or the discharge opening *h* may be arranged so that some small crystals are discharged with the large crystals. The separation by settling may be effected by leading a part of the circulating flow through a pipe *k*, Fig. 1, into the lower part of the vessel *b* in which settling occurs and from which the liquid passes again into the main circulation. Supersaturation of the solution may be effected by cooling the solution at the surface *o* of the vessel *b*, the superheater *a* being dispensed with. The evaporation or cooling may be accelerated by blowing air through the solution. (Br. Pat. 171,370. Not yet accepted. Aktieselskabet de Norske Saltverker, Bergen. Dec. 31, 1921.)

Chromic Sulphate.—Chromate or bichromate of sodium or potassium is treated with sulphuric or other acid to give a solution of chromic acid. The latter is freed from the alkali salt present by cooling to 0 deg. F. and separating the resulting crystals, preferably by centrifugal action. The chromic acid, on saturating with sulphur dioxide, gives a chromic sulphate solution. The alkali salt may be removed from the extractor by dissolving the crystals in water. (Br. Pat. 171,149. F. M. Mooney, Montreal. Dec. 30, 1921.)

Tanning Materials.—Waste sulphite-cellulose lye is treated with lime or calcium carbonate to neutralize the acids, and is separated from the precipitate. The calcium is then precipitated by alkali compounds such as sodium carbonate or silicate. Hydrochloric, sulphuric or other acid is added to the resulting solution of sulpho-lignates in amount equivalent to 50 to 100 per cent of the alkali used in precipitation. The liquid can then be used for tanning. Instead of acid, there may be added salts of metals such as are used in mineral tanning—for instance, aluminum, iron, or chromium chloride; the liquids thus obtained can be used directly for tanning. The liquid may be fermented after the addition of the lime or calcium carbonate, and may be concentrated by evaporation after the treatment with the alkali compound. (Br. Pat. 171,136. A. Romer, Stuttgart, and Deutsch-Koloniale Gerb. & Farbstoff Ges., Karlsruhe. Dec. 31, 1921.)

Heat- and Sound-Insulating Material.—A heat- and sound-insulating composition comprises slag wool or other fibrous material such as asbestos, hair felt, fossil earth and aqueous solution of casein, a sodium compound such as borax, soda ash or caustic soda and tung oil, or coal tar, pitch or asphaltum. Preferred proportions are slag wool 100 parts, casein 10 to 15 parts in 100 parts of water, tung oil 10 to 15 parts, borax 3 parts. The fibers are placed in a container, the other ingredients are boiled together and added, the manhole cover is screwed down, and compressed air or steam is admitted to mixing jets. The mixture is then forced into a porous or perforated mold. The composition may be applied directly to steam pipes, etc. (Br. Pat. 171,550. H. Smith and J. Fullock, London. Dec. 31, 1921.)

Purifying Cellulose Solutions.—Cellulose solutions such as are used for spinning artificial threads are freed from foreign or undissolved particles by subjecting the solutions to powerful centrifugal force. The separation may be effected in a rapidly rotating hollow cylinder, bottle shaped at the upper part and suspended vertically in ball bearings; the solution is introduced through an opening in the base of the cylinder, overflows at the neck and is collected in a surrounding rim, while the particles thrown out by centrifugal force collect as a compact layer along the walls of the cylinder, and are from time to time removed. For effective separation, the value of the centrifugal force must be higher than that ordinarily employed; thus with a cylinder having an internal diameter of 10 cm., the speed of revolution must be 15,000 r.p.m. or higher. (Br. Pat. 171,384. Not yet accepted. K. Fürst, Berlin. Dec. 31, 1921.)

Heat-Insulating Coverings.—Relates to heat-insulating coverings for the pipes of refrigerating machines and the like of the kind comprising a tubular sheath of fibrous material filled with granulated cork or similar material and adapted to be wrapped as a rope in one or more layers around the pipe. According to the invention, a sheath is made in a braiding machine and the granulated material is simultaneously delivered from a shoot, being guided into the sheath by means of a ring of warp threads which pass through the chute into the rope and form an integral part of the finished rope. (Br. Pat. 171,428. A. Nadin, Lancashire. Dec. 31, 1921.)

Glass Manufacture.—Black glass, which is of use as an electric insulating material, and which has a small thermal expansion, is made by melting a natural rock, such as schist, consisting chiefly of quartz, lime and alumina, and adding a further quantity of one or more of these substances until the melted product contains approximately 1 part aluminum oxide, 1.65 parts calcium oxide, and more than 3.56 parts of silica, the excess of silica beyond 3.56 parts being calculated so that all other oxides present may be converted into silicates. The main ingredient of the finished product has the chemical formula $(SiO_2)_6$, Al_2O_3, $(CaO)_3$ and melts at about 1,250 deg. C. (Br. Pat. 171,692. Not yet accepted. P. T. Freuler, Schwanden, Switzerland. Jan. 11, 1922.)

Technical News of the Week

Current Events in the Chemical, Metallurgical and Allied Industrial Fields—Legislative Developments—Activities of Government Bureaus, Technical Societies and Trade Associations

Secretary Weeks Doubtful of Ford Offer at Initial Hearing Before House Committee

Doubt as to the ability of Henry Ford to reduce materially the cost of fertilizer by the operation of the Muscle Shoals nitrate plant was expressed by the Secretary of War at the initial hearing on the Ford offer before the Military Affairs Committee of the House of Representatives. If he were convinced that, by the acceptance of this offer, the price of fertilizer could be reduced materially to the farmer, Secretary Weeks said, he would vote for its acceptance if he were a member of Congress. In view of the doubt as to the ability of Mr. Ford to cheapen fertilizers, Secretary Weeks expressed the personal opinion that more advantageous schemes for the utilization of the power at Muscle Shoals could be worked out. He said that the part of the contract referring to the obligation to produce 110,000 tons of ammonium nitrate per annum is not in business-like form. He called attention, however, to the generally held belief that the fixation of nitrogen is in its infancy and that great development in this art may be expected in the next few years.

Thinks Ford Would Accept Modifications

The attitude of the committee is evidently one of establishing whether or not the Ford offer is a business-like proposition. In answer to questions, Secretary Weeks expressed the personal opinion that Mr. Ford would accept modifications which will make the offer a very much better one. In justifying his apparent delay in handling the Ford offer, Secretary Weeks pointed to the fact that the offer in its present form not only establishes additional safeguards for the public interest, but is tantamount to an increase of about $14,000,000. He revealed that Mr. Ford is contemplating the immediate investment of $10,000,000 to $12,000,000 of his own funds, in addition to the amounts which Congress would be called upon to expend on dam construction.

Does Not Favor Government Operation

The Secretary emphasized his opposition to any attempt to embark the government in the manufacture of fertilizer. If the Ford offer is not accepted, he favors the completion of the dam by the government, but he made it very clear that the government's activity should not be extended to include the operation of the nitrate plant.

Few new points were brought out during the Secretary's testimony. He amplified the explanation contained in his letter transmitting the Ford offer and gave new emphasis to many points. Among those was his insistence that the lease should be for no longer period than 50 years. He also suggested that any sale of power by Mr. Ford, in case he did not use the entire output for his own industries, should be under regulations to be formulated by the Federal Power Commission.

That difficulties may be expected in adjusting claims with the Alabama Power Co. and that a substantial sum will be required to purchase the right of way for the 88-mile transmission line to the Warrior River plant, were predicted by Secretary Weeks.

Urges Guarantee of Continuous Operation

He urged that responsibility should be definite with regard to the manufacture of nitrate. There is difference of opinion as to whether or not the agreement would compel the operation of the nitrate plant at a loss. The Secretary suggested that there should be a guarantee, either by the formation of a company with sufficient capital or by the giving of a bond in sufficient amount, to insure the continuance of this operation throughout the life of the contract.

While several members of the committee very obviously have preconceived ideas as to just what ought to be done with the Ford offer, most of them appear to be open to conviction.

Bill for Reclassification of Technical Employees in Federal Service Reported to Senate

The bill reclassifying employees in the federal service, which was passed recently by the House of Representatives, has been reported to the Senate by its Committee on Civil Service with important amendments. The Senate committee has substituted the Civil Service Commission for the Bureau of the Budget as the classifying agency and has increased the salary range for professional and scientific services. In addition, the professional groups have been expanded so as to include editors, illustrators, transportation experts and nurses. The Senate bill also extended the classification to the field services. The House bill limited the compensation schedules to civilian employees in the District of Columbia.

Provides for Efficiency Records

The bill permits the transfer of employees between departments at a higher rate of payment. It establishes an efficiency rating system, and provides that the efficiency records are to be accessible to employees. The bill establishes a minimum efficiency standard which must be maintained or the employee will be dropped from the list. In reporting the bill Senator Sterling, the chairman of the committee, said in part:

> For the professional and scientific service the committee would restore the rates recommended by the reclassification commission. Under that scale the entrance salary for the lowest positions requiring scientific or professional training equivalent to that reached by graduation from a college or university would be $1,800 instead of $1,620. To the highest successful professional or scientific man who is placed in full administrative charge of a major professional or scientific bureau, it would pay from $6,000 to $7,200 unless a higher salary is specifically authorized by law. The House bill would give such an employee $5,400 to $6,600 unless a higher salary is specifically authorized by law. Such a change would add less than 2 per cent to the cost of reclassification.
>
> The government probably never can compete on the basis of salary with private business and industrial enterprises seeking to secure scientific and professional services. Those salaries, however, should bear a fairly close relationship to those being paid by the largest and strongest colleges and universities of the country.

Since the measure affects the budget, the bill does not go directly to the Senate calendar, but was referred to the Committee on Appropriations. There is a possibility that the Appropriations Committee will insist that it take its turn and follow the regular appropriation bills, which would mean a delay of many weeks.

New Chemical Laboratory Planned for University of West Virginia

The University of West Virginia, Morgantown, is having plans prepared for the erection of a new chemical laboratory at the institution, estimated to cost about $400,000. It is expected to call for bids late in February or early in March. Paul A. Davis, 1713 Sansom St., Philadelphia, Pa., is architect.

Dr. Richards' Metallurgical Library Given to Lehigh

In accordance with the will of the late Joseph W. Richards, his entire personal technical library of over 5,000 volumes has been donated to the department of metallurgy of Lehigh University. Dr. Richards, who was head of the department at the university until his death, felt the need of a complete library of metallurgical volumes separate from the university library. The removal of the standard works on metallurgy from the university library to supplement the Richards collection is being considered and would give the university one of the most complete metallurgical libraries in the country.

Industrial Developments of the Week

Glass. The Indiana Window Glass Co., Vincennes, Ind., has resumed operations at its plant, following a considerable period of curtailment. Employment will be given to more than 300 men.

The Hawley Glass Co., Hawley, Pa., manufacturer of bottles and other hollowware products, has reopened its plant after a shutdown of about 7 months. Orders are said to have been received to insure continuous operation well into next fall.

The Tampa Glass & Bottle Manufacturing Co., Tampa, Fla., recently organized to succeed the Southern Bottle Manufacturing Co., is arranging for the resumption of operations at the local plant before the close of the month.

The different window glass plants in the Clarksburg, W. Va. district are resuming operations, and since the first of the month about 2,500 workers have returned to the factories.

Paper. The Warren Manufacturing Co., Milford, N. J., has recently added about fifty men to its working force and is operating at full capacity. The company manufactures glassine and other papers.

J. G. Wieder, Macungie, Pa., operating a paper box-manufacturing plant, has adopted a night working schedule for increased production.

Rubber. The Fiske Tire Co., Chicopee Falls, Mass., has increased production at its local plant to about 9,000 tires a day, as compared with 3,000 per day during the low point of manufacture last spring. It is planned to advance the output gradually during March, April and May until capacity of about 15,000 casings per day is reached. The Cudahy, Wis., branch of the company is maintaining an output of about 3,000 tires a day.

The Du Bois Tire & Rubber Co., Chattanooga, Tenn., has commenced operations at its new local plant, recently completed, and is said to have taken orders to insure capacity output for the entire year.

The B. F. Goodrich Co., Akron, Ohio, has adopted a production schedule of from 17,000 to 18,000 casings a day at its local works.

Cement. Practically all of the cement companies in the Nazareth, Pa., district have adopted a night shift at their mills for increased production, including the Nazareth Cement Co., Phœnix Portland Cement Co., Hercules Cement Corporation and the Dexter Portland Cement Co. The mills are giving employment to more than 3,000 workers.

Iron and Steel. The Scranton Iron & Steel Co., Scranton, Pa., has resumed production at close to normal in all departments of the plant for the first time in several months.

The Cumberland Steel Co., Cumberland, Md., has recently resumed production at its plant following a short shutdown.

For the first time in many months the Allegheny Steel Co., Brackenridge, Pa., is operating at practically 100 per cent in all departments of the works.

The Inland Steel Co., Chicago, Ill., is increasing production at its mills to close to 75 per cent capacity.

The Cambria Steel Co., Johnstown, Pa., has placed three more open-hearth furnaces at its Franklin Works in operation, making a total of fifteen furnaces in service. The No. 3 mill at the lower plant has also been reopened.

Coke. After more than a year of idleness, the H. C. Frick Coke Co. has resumed partial operations at its Colonial No. 3 and Hecla No. 1 plants in the Uniontown, Pa., section.

Miscellaneous. The Nickel Alloy Co., Hyde City, near Clearfield, Pa., has resumed operations, following a shutdown for about 13 months past. The production will be devoted exclusively to nickel alloys and steel manufacture will be entirely discontinued.

The J. B. Ford Co., Detroit, Mich., manufacturer of soda ash, etc., is increasing production at its plant, and during the first 3 weeks of January the output was larger than for any month during the past year.

Procter & Gamble, Kansas City, Mo., manufacturers of soaps, etc., are operating their local plant at close to normal, with regular force of employees.

The Mathieson Alkali Works, Niagara Falls, N. Y., have increased production at their local plant to about 80 per cent of capacity.

Fire destroyed the main building of the American Aniline Products, Inc., plant at Lock Haven, Pa., on Feb. 1. The fire originated in one of the color grinding mills and destroyed considerable quantities of raw materials and finished dyes, the loss being estimated at $200,000.

Voluntary Refund of Excess War Profits by Eastman Kodak Co.

The Eastman Kodak Co. has presented to the government a check for $182,770.60, representing the profit of the company on apparatus and materials for the Aircraft Service of the War Department in excess of 10 per cent. In the letter accompanying this purely voluntary refund George Eastman explained that in accepting the contracts from the government during the war, the company had no definite figures upon which to base costs and it was necessary to make a liberal estimate in order to protect the company against loss. As soon as the complete final cost figures could be compiled, the profit in excess of the agreed 10 per cent, represented by the present payment, was made.

Acknowledgment was made by General Pershing as acting Secretary of War in the following letter:

> My dear Mr. Eastman: In receiving your check for $182,770.60, representing the monetary refund to the government by the Eastman Kodak Co. of its profits on War Department war contracts in excess of 10 per cent, I wish to express to you my high appreciation of this fine and patriotic action on the part of your company. Such a wholesome and generous attitude might well be expected during war times, but with the lapse of 3 years since the armistice, it is truly refreshing and inspiring to find such motives and high ideals animating a large business organization in its relation with the government.
>
> JOHN J. PERSHING,
> Acting Secretary of War.

Start of Dye Investigation Still Indefinite

An organization meeting of the sub-committee of the Senate Committee on the Judiciary which will conduct the dye investigation was held Feb. 7. Senator Shortridge was designated as chairman of the sub-committee. The date for the first open hearing will not be fixed until Senator Reed can be present.

The attitude of the American Dyes Institute with respect to the inquiry was made known in a letter by R. C. Jeffcott, addressed to Senator Shortridge.

"The American Dyes Institute and its members wish to let you know that they want to co-operate with you and facilitate your labors in every way," the letter states. "The resolution is comprehensive, and those engaged in the dye industry of the country welcome a most thorough and impartial examination of all questions covered by it."

Patent Bill Near Final Stage

Approval of the plan for the early consideration of the Patent Office relief bill has been secured from Senate leaders. It is expected that the bill will be called up in the very near future and passed with a minimum of discussion.

Soap, Oil and Alkali Manufacturers Ask for Lower Freight Rates

Petitions were presented to the Interstate Commerce Commission Feb. 8, asking for a reduction in the freight rates on cottonseed oil, soaps and soda ash, bicarbonate of soda and caustic soda. The petitioners represented the Southern Cotton Oil Co., the American Cotton Oil Co., all of the manufacturers of nationally advertised and distributed soaps and the members of the Alkali Manufacturers' Association.

It was testified that in general wages and other operating costs have been reduced to about 140-150 per cent of pre-war, while the freight rates on these products remain at 180-220 per cent of the pre-war level.

S. J. Cassels, the district manager for the Southern Cotton Oil Co. at Montgomery, Ala., testified that in 1921 only 300 of the 750 cottonseed crushing mills were in operation throughout the entire season. Two hundred operated at part time but the remainder were closed down continuously. To some extent this was due to the shortage in the cotton crop, but the witness said that the high freight rates have been a contributing cause. They have had the effect of localizing the business of each mill so that it could draw its seed only from short distances and likewise limited it in distributing cattle feed, fertilizer and other bulky byproducts.

American Welding Society Issues First Copy of Its "Proceedings"

The American Welding Society has issued, under date of January, 1922, the first copy of its *Proceedings*, in the form of a well-printed 44-page pamphlet. About half the space is taken up with society activities, related news and a bibliography of welding literature. The remainder is filled with technical papers, discussing methods and principles of various phases of welding.

This society was organized in 1919, and an attempt was then made to issue a journal, but it proved too expensive. Then for more than a year the *Welding Engineer* gave part of its space for the society proceedings. Even with the best will in the world, such an arrangement could not prove altogether satisfactory to each party, and the present *Proceedings* is an attempt to improve the society's service to its members.

Navy Department Solicits Bids

The Bureau of Supplies and Accounts, Navy Department, Washington, D. C., will receive bids up to Feb. 28 for 15,000 lb. of lump rosin; 200 qt. of liquid bronze; 5,000 gal. of turpentine, and 3,000 lb. of artificial vermilion, for use at the Mare Island (Cal.) Navy Yard. (Schedule 9420.)

Personal

E. O. Benson, Jr., has left the Jackson Laboratory of E. I. du Pont de Nemours & Co., Wilmington, Del., to accept a position as research chemist with John Campbell Co., manufacturer of dyestuffs, Newark, N. J.

G. S. Brown has been re-elected president of the Alpha Portland Cement Co., Easton, Pa.

Dr. Harold S. Davis has resigned from his industrial fellowship at the Mellon Institute of Industrial Research of the University of Pittsburgh to accept a position on the research staff of Arthur D. Little, Inc., Cambridge, Mass.

Philip DeWolf has severed his connection with the Davison Chemical Co. and entered consulting work, with headquarters at Westport, Conn. He will specialize in the manufacture of sulphuric acid, problems of evaporation and the industrial applications of silica gel.

William C. Dudley has been re-elected president and general manager of the Dudley Paper Co., Lansing, Mich.

Andrew H. Green, Jr., vice-president of the Solvay Process Co., Syracuse, N. Y., and connected with that organization for many years, has been elected president and general manager of the Charcoal Iron Co. of America, Detroit, Mich., succeeding Frank W. Blair, resigned.

J. S. Negru, Managing Editor of Chemical & Metallurgical Engineering, sailed Feb. 11 for a 6 months' trip through Germany, France, Belgium and other European countries. The purpose of the trip is to study industrial and economic conditions and observe the latest advances in science, engineering and technology.

Dr. Ernest Fox Nichols, who recently resigned the presidency of the Massachusetts Institute of Technology, Cambridge, Mass., is to return to Cleveland to resume the directorship of pure science research in the Nela Research Laboratory of the General Electric Co.

Dr. William H. Nichols, chairman of the board of trustees of the Brooklyn Polytechnic Institute for the past 17 years and a member of the board for 32 years, has resigned. He will, however, continue to serve the Institute as vice-chairman.

F. W. Pickhard, one of the vice-presidents of E. I. du Pont de Nemours & Co., has been appointed general manager of the dyestuffs department, with W. F. Harrington as assistant manager. C. A. Meade, vice-president and former general manager of the dyestuffs department, and M. F. Poucher, former director of sales, have been made executive staff officials.

James H. Ransom has changed his position as research chemist with the Michigan Smelting & Refining Co., Detroit, Mich., to head the department of chemistry in James Millikin University, Decatur, Ill.

J. W. Smith and D. R. Sharpe, superintendent and manager, respectively, of the minerals department of the Louisiana State Conservation Commission, have resigned.

Robert Steinemann has been elected vice-president and general manager of the Tide Water Corp., New York, following his recent resignation from the National Aniline & Chemical Co., Inc.

Bradley Stoughton, formerly secretary of the American Institute of Mining and Metallurgical Engineers, was elected president of the Yale Engineering Association at the annual meeting on Feb. 2, 1922.

Obituary

Thomas Francis Crowley, for about half a century past prominently identified in an official capacity with the Lambertville Rubber Co., Lambertville, N. J., died at his residence in that city, Jan. 29, at the age of seventy-four years.

Charles Lewis Taylor, E.M., Eng.D., prominent as a metallurgist, chemist and philanthropist, died on Feb. 3 at his winter home in Santa Barbara, Cal. Mr. Taylor was born in Philadelphia on April 3, 1857, and was graduated from Lehigh University in the class of 1876. He was connected with the Cambria Iron Co. at Johnstown, Pa., as assistant chemist and later as assistant superintendent of blast furnaces. He was superintendent of the Homestead works of the Pittsburgh Bessemer Steel Co. from 1882 to 1886 and the development of the present methods of production of steel pipe, nails and ship plate was due largely to his ability as a chemist and metallurgist. He was general manager of the Hartman Steel Co. of Pittsburgh until 1890, when he became associated with Andrew Carnegie in the firm of Carnegie, Phipps & Co., Ltd., and later became Mr. Carnegie's assistant in the Carnegie Steel Co. Mr. Taylor retired from active business in 1901 and devoted his time and energy to philanthropic work. He was president of the Carnegie Hero Fund Commission and chairman of the Carnegie Relief Fund from the time of their foundation in 1904. He was also a trustee of the Carnegie Peace Fund, the Carnegie Library, Carnegie Institute, Carnegie Institute of Technology and Lehigh University. In his biography Mr. Carnegie states, in referring to a dormitory building donated by him and named in honor of Mr. Taylor: "Visitors who may look upon that structure and wonder who Taylor was may rest assured that he was a loyal son of Lehigh, a working, not merely a preaching, apostle of the gospel of service to his fellow men and one of the best men that ever lived."

Market Conditions

IN CHEMICAL, METALLURGICAL AND ALLIED INDUSTRIES

A Survey of the Economic and Commercial Factors That Influence Trade in Chemicals and Related Commodities—Prevailing Prices and Market Letters From Principal Industrial Centers

Statistics of Chemical Production

The study and compilation of the statistics collected for the 1919 census of manufactures have now proceeded to the stage where accurate comparisons can be made with the results of prior censuses. Through the courtesy of the Bureau of the Census, certain of the chemical industries are now being furnished with detailed statistics in approximately the form in which they will appear in the tables of the forthcoming Abstract. Revisions have been made in many of the preliminary totals published in CHEMICAL & METALLURGICAL ENGINEERING for Sept. 7, 1921, and much additional information is included, notably that regarding the number of establishments, and the production for sale and for direct consumption. The final report of the Census Bureau will show the distribution of these establishments by states and cities as well as detailed data concerning the number of wage earners, power and fuel consumption, etc.

From time to time it is our intention to publish the more important of these statistics as they relate to the chemical and allied industries. It is unnecessary, perhaps, to point out that the value of the 1919 figures lies principally in their relation to our maximum peace-time production. In other words, they represent capacities of these industries after most, if not all, of the war-time activities had been discontinued. In the case of some chemical products, the maximum rate of output was probably reached in 1920, while in the cases of others, the consumption of war-time reserves inhibited production both in 1919 and 1920. However, it is believed that 1919 is a satisfactory year for comparing productive capacity with that of 1914 and of 1909.

THE ACID INDUSTRIES, 1909—1919

The detailed statistics for the production of the principal acids during the last three census years are compared in the accompanying tabulation. It will be noted that the total value of products increased from $32,837,254 in 1914 to $87,011,618 in 1919. It would appear at first glance that our output of these products had more than doubled, but when correction is made for the greatly increased prices of 1919 it will be observed that the increase is but slightly more than that which occurred during the 5-year period 1909-1914. The CHEM. & MET. Index of Chemical Prices for 1919 was 242 per cent of 1913-1914 figures. If the value of the 1914 production is increased in this proportion, we obtain the figure $79,500,000, which is only approximately 7.5 million dollars less than the reported value of the 1919 output. The increase between 1909 and 1914 was about 6.8 million dollars.

The output of the inorganic acids in 1919 showed less relative increase than did the organic acids. However, the quantities reported for each of the individual acids increased with the exception of hydrofluoric, acetic, tannic and certain strengths of sulphuric acid. In several instances there are decreases in the number of establishments, indicating larger scale of operations and possible merging of producing interests.

CHEMICAL & METALLURGICAL ENGINEERING'S WEIGHTED INDEX OF CHEMICAL PRICES

Base = 100 for the year July 1, 1913, to June 30, 1914

This week	147.46
Last week	147.33
February, 1921	166
February, 1920	252
April, 1918 (high)	286
April, 1921 (low)	140

The index number remains practically unchanged notwithstanding the continued strength of the vegetable oil markets. The higher prices for cottonseed and linseed oils were almost entirely offset by the lower figures quoted for hydrochloric acid, bleaching powder, soda ash, caustic soda and caustic potash.

PRODUCTION OF PRINCIPAL ACIDS IN 1919 COMPARED WITH PRODUCTION IN 1909 AND 1914.

(Census of Manufactures, 1919)

[1] Not separately reported.
[2] Includes a large production under a long-term, low-priced contract.
[3] Includes "Battery acid" and "Electrolyte sulphuric." 4,694 tons.
[4] Included above with oleum.
[5] Includes, 1919, chlorsulphuric, chromic, hydrobromic, hydrofluosilicic, hydrophosphorous, molybdic, silicic, tungstic, vanadic, etc., and for 1914, sulphurous, hypophosphorous, arsenic and hydrofluosilicic.
[6] Includes, 1919, butyric, caproic, carbolic, oresylic, formic, gallic, glycerophosphoric, hydrocyanic, monochloracetic, oxalic, phthalic anhydride, propionic, pyrogallic, thymol and valerianic.

Mathieson Alkali Works to Show Deficit for 1921

The forthcoming annual report of the Mathieson Alkali Works is expected to show a deficit of about $200,000 after the charges have been made to the depreciation account. It is reported that since October the company has been operating at a profit and at the present time its earnings are at the rate of about $8 per share on its common stock.

Recent Activity of Davison Stock

The recent advances in the quotations for the stock of the Davison Chemical Co. have occasioned considerable interest in the activities of the company as well as of its subsidiary, the Silica Gel Corporation. The stock of the Davison company advanced to 62⅜ on Jan. 25 and at the end of the day had shown a net gain of 5⅜ points. Since that time the stock has been held at 60 or above. Although there is considerable mystery surrounding the present flurry, it is generally believed that the activity is a direct result of certain negotiations between the Davison company and the Persian Oil Co. of Great Britain, which is said to be interested in using the silica-gel process for refining gasoline. The process is now being tried out on a considerable scale in the East Braintree (Mass.) plant of the Island Oil & Transport Co.

Recent financial statements of the Davison Chemical Co. are not available, but according to the *Wall Street Journal*, the net earnings of $822,602 for the year ended Dec. 31, 1920, were equal to $4.11 a share on the outstanding 200,000 shares of stock of no par value, after deductions had been made for expenses, interest, depreciation and revaluation of ore stocks in Cuba. In 1919 the earnings were $1.91 per share. It should be pointed out, however, that these profits are based on the company's business in sulphuric acid and acid phosphate. As yet there have been no earnings from the Silica Gel Corporation.

The New York Market

NEW YORK, Feb. 13, 1922.

The chemical market during the past week showed little signs of recovering and in general transactions were limited to orders for immediate requirements. Miscellaneous chemicals were more active during recent sales, but prices in many instances had to be sacrificed. Producers of late are acquiring most of the regular consuming business.

The alkali trade is apparently well covered by standing contracts as far as the leading consumers are concerned and competition on any new business of sizable proportions is extremely keen. The export situation on caustic soda is a trifle better with several new transactions reported to Italy and Japan. A feature in the alkali market was the entry of Germany as a buyer of caustic soda. Recent internal disturbances are said to be the cause of the purchases of that country. South American markets have not shown any signs of real activity, but it is believed that Argentina will probably offer a market as soon as conditions have become more sound. Other countries are buying alkalis in a moderate way.

In many instances large quantities of imported chemicals have been offered in the open market at prices which represent heavy losses to the importers. Among these products are cyanide of soda, chlorate of soda, caustic potash, citric acid, salammoniac and others. The principal explanation for this situation has been the irregular delivery and poor quality of the foreign goods. Preference for American cyanide and salammoniac has recently been shown in several transactions where buyers paid the differential as an assurance for quality and delivery.

General Chemicals

Bleaching powder is becoming more irregular under a keener state of first-hand competition. Orders for domestic consumption were accepted by producers at 2c. per lb., f.o.b. works. Bichromate of soda was steadier on spot with only a small-lot inquiry being noted. It is doubtful if better than 7¾c. per lb. could be obtained. Prussiate of soda sold at lower prices, with sales reported down to 16¾c. per lb. Shipments were also quoted at this figure c.i.f. N. Y. The demand was not as active as earlier in the year. Oxalic acid is holding steady both on spot and at the works. Prices have remained firm on spot at 14½@15c. per lb., with works material held around 14c. Sales of yellow prussiate of potash were recorded during the week at 24¾@25c. per lb., with the higher figure generally asked by most sellers of spot material. The red variety is entirely nominal, owing to the scarcity of supplies.

Resale lots of imported caustic potash, 88-92 per cent, are in the market at $5.55 per 100 lb., and it is understood that sales have been made down to 5½c. per lb. It is surprising to note the decline in prices on this chemical when existing conditions seem to show every tendency to advance it. There is a steady absorption of resale material owing to a firmer condition developing in the German market and the fact that leading importers feel very doubtful if stock can be replenished at current quotation. Export inquiries on caustic soda have been sufficiently active to permit dealers to place some business, although prices have been subject to shading. Dealers quoted $3.35 @$3.40 per 100 lb. f.a.s. Some of the larger interests quote the market around $3.45. Nitrite of soda was reported very scarce on spot by leading factors, with a noticeably improved inquiry. Prominent sellers refused to trade 7c. per lb. at the close of the week and several sales of carload quantities were recorded at this figure. Prices of domestic soda ash on spot have drifted to a slightly lower level, single bags being offered at $1.65 per 100 lb. in carload lots.

Linseed Oil

There was a substantial rise recorded in linseed oil when the market closed at 78c. per gal. in barrels for carlots. The rising market, however, did not bring with it much new business, most consumers evidently being covered for February-March-April. Imported oil was subject to some violent fluctuations, business passing at prices ranging from 58@63c. per gal., duty unpaid, c.i.f. New York, for February-March shipment from abroad.

The Chicago Market

Chicago, Feb. 10, 1922.

The heavy chemical market continues exceedingly quiet, with no developements worthy of notice. Buyers show a pronounced reluctance to come into the market and are buying only very small supplies for immediate consumption. A variety of prices are obtainable from the small brokers, but manufacturers or their agents are making no effort to meet this competition. It is noticeable that many buyers will pay a somewhat higher price for an item from a manufacturer rather than go to a small dealer or broker. Supplies of most items are only moderate, although it is said that a few speculators are carrying rather heavy stocks.

General Chemicals

The alkali situation is unchanged, with spot stocks only moderate and current quotations unchanged. There is little doubt that prices could be shaded with firm business. Ground caustic soda, 76 per cent, is quoted at $4.50 per 100 lb. and the solid at $3.75. Soda ash continues quiet and is offered at $2.30 per 100 lb. for medium-sized lots in cooperage. There is a small amount of caustic potash moving and the price is firm at 6½c. per lb. for the 88-92 per cent material.

Potash alum is quiet on spot, with only small lots moving. The lump is quoted at 5½@6c. per lb. and the powdered at 6@6½c. Iron-free aluminum sulphate is slow and unchanged at 3¼c. per lb. White arsenic continues firm with only small quantities available at 8@8½c. per lb. Barium chloride is obtainable on spot at $55 per ton but little is moving. Small quantities of blue vitriol changed hands at 5c. per lb. but nothing of any consequence was reported. Holders report a fair demand for borax, which is quoted at 5c. per lb. for single barrels. Carbon bisulphide is very quiet and spot stocks are still quoted at 7@7½c. per lb. Carbon tetrachloride is in a similar position and large drums are offered at 11c. per lb. Glycerine is very firm, with c.p. material quoted by refiners at 16½@17c. per lb., bulk basis. Epsom salts attract little attention and are quoted at 2¾c. per lb. for U.S.P. material in barrels.

Bichromates are enjoying a fair demand for small lots and are unchanged as to price. Potash bichromate is offered at 11¾c. per lb. in single casks and similar lots of the soda at 9½c. Red prussiate of potash is entirely off the market and not a single pound could be located. Single casks were offered to arrive at 52@55c. per lb. Yellow prussiate of potash is firm at 26@27c. acording to quantity and holder. Potassium permanganate is very slow with spot U.S.P. crystals quoted in small lots at 17@18c. per lb. Hypo is very quiet at $3.95 per 100 lb. for pea crystals in barrels.

Vegetable Oils and Naval Stores

Linseed oil is reported to be moving very slowly, although the price is showing unusual firmness. The boiled oil is quoted at 82c. per gal. in 5-bbl. lots and similar quantities of the raw at 80c. Higher prices on this oil are freely predicted by all factors.

Turpentine, like linseed oil, while very firm as to price, is moving very slowly. Pure spirits are quoted in 5-drum lots at 96c. per gal. Rosin is showing firmness and is said to be moving fairly well to the paper trade. Prices lacked quotable change and were only nominal for less than carlots.

The Iron and Steel Market

Pittsburgh, Feb. 10, 1922.

The improvement in the volume of steel orders placed since the first of the year is found by the January ingot production report to have been greater than commonly estimated. The American Iron and Steel Institute's report, giving the production of steel ingots in January by the thirty reporting companies, indicates that production by the industry as a whole was at the rate of about 22,750,000 tons per annum during January. The average production during December was about 19,750,000 tons, and as production during December was declining, the rate at the close of the month was much less, probably between 16,000,000 and 18,000,000 tons. From such a rate there has been a more or less progressive increase to date, and with a January average of about 22,750,000 tons the rate by this time may be close to 25,000,000 tons. If so, we have already exceeded the high level of last autumn, shown by a production rate of 23,000,000 tons during October and November. Meanwhile there has been a lull, which is to be attributed to its being winter rather than to the much mentioned holidays and annual inventory.

Competition for steel orders continues keen. The openly quoted or "regular" prices are practically unchanged, but the average price realized on all the tonnage sold has probably been sagging a trifle from week to week. The extreme prices may be much the same, but smaller and smaller orders, in many commodities, become subject to concessions from the "regular" prices. Apart from general shading, there is the case of mills well removed from Pittsburgh departing from "Pittsburgh plus." Chicago has long had its own basing for bars, shapes and plates, 1.60c., as against a Pittsburgh market of 1.50c., while by "Pittsburgh plus" the Chicago market would be 1.88c., the freight Pittsburgh to Chicago being 38c. per 100 lb. Of late the East has likewise departed, Eastern mills making delivered prices which Pittsburgh producers do not meet when they represent extreme concessions.

Pig Iron and Coke

In most districts pig iron continues to show a slight sagging tendency, with now and then a definite, though small, decline. Many buyers doubt whether prices are really below cost of production, as so generally claimed by furnaces.

Connellsville coke has undergone a sharp stiffening in the past week, mostly because of the threatened suspension at the union bituminous coal mines April 1. The trade generally regards the suspension as assured, and assumes that the non-union mines will not be able to supply the entire demand. Some foundries are stocking foundry coke, while Connellsville coke operators are turning their attention to coal, which even at recent prices has been bringing more as coal than when made into coke. Spot furnace coke of fair grade could be had a week ago at $2.75, while at present no passable coke is available at under $2.85 and the best grades command $3. Foundry coke remains quotable at $3.75@$4.25, but there is little at the lower prices and much more request for the $4.25 brands.

General Chemicals

CURRENT WHOLESALE PRICES IN NEW YORK MARKET

		Carlots	Less Carlots
Acetic anhydride	lb.	—	$0.40 – $0.42
Acetone	lb.	$0.12½ – $0.12¾	.13 – .13½

Coal-Tar Products

NOTE—The following prices are for original packages in large quantities:

Alpha-naphthol, crude	lb.	$1.00 — $1.05
Alpha-naphthol, refined	lb.	1.10 — 1.15
Alpha-naphthylamine	lb.	.28 — .30
Aniline oil, drums extra	lb.	.17 — .18
Aniline salts	lb.	.24 — .26
Anthracene, 80% in drums (100 lb.)	lb.	.75 — 1.00
Benzaldehyde U.S.P.	lb.	1.30 — 1.35
Benzidine, base	lb.	.85 — .95
Benzidine sulphate	lb.	.75 — .85
Benzoic acid, U.S.P.	lb.	.60 — .65
Benzoate of soda, U.S.P.	lb.	.55 — .57
Benzene, pure, water-white, in drums (100 gal.)	gal.	.29 — .35
Benzene, 90%, in drums (100 gal.)	gal.	.27 — .32
Benzyl chloride, 95-97%, refined	lb.	.25 — .27
Benzyl chloride, tech	lb.	.20 — .23
Beta-naphthol benzoate	lb.	3.75 — 4.00
Beta-naphthol, sublimed	lb.	.60 — .65
Beta-naphthol, tech	lb.	.29 — .32
Beta-naphthyla mine, sublimed	lb.	1.50 — 1.60
Cresol, U. S. P., in drums (100 lb.)	lb.	.16 — .17
Ortho-cresol, in drums (100 lb.)	lb.	.20 — .22
Cresylic acid, 97–99%, straw color, in drums	gal.	.50 — .52
Cresylic acid, 95-97%, dark, in drums	gal.	.45 — .47
Dichlorbenzene	lb.	.06 — .09
Diethylaniline	lb.	1.00 — 1.10
Dimethylaniline	lb.	.41 — .45
Dinitrobenzene	lb.	.21 — 25
Dinitroclorbenzene	lb.	.25 — 27
Dinitronaphthalene	lb.	.32 — .35
Dinitrophenol	lb.	.35 — .38
Dinitrotoluene	lb.	.25 — 30
Dip oil, 25%, car lots, in drums	gal.	.28 — 30
Diphenylamine	lb.	.60 — .70
H-acid	lb.	.90 — 1.00
Meta-phenylenediamine	lb.	1.00 — 1.05
Monochlorbenzene	lb.	.10 — .12
Monoethylaniline	lb.	1.15 — 1.20
Naphthalene crushed, in bbls.	lb.	.07 — .08
Naphthalene, flake	lb.	.07 — 08
Naphthalene, balls	lb.	.08 — .09
Naphthionic acid, crude	lb.	.65 — .70
Nitrobenzene	lb.	.10 — .12
Nitro-naphthalene	lb.	.30 — .35
Nitro-toluene	lb.	.15 — .17½
Ortho-amidophenol	lb.	2.75 — 2.80
Ortho-dichlor-benzene	lb.	.15 — .20
Ortho-nitro-phenol	lb.	.75 — .80
Ortho-nitro-toluene	lb.	.15 — .20
Ortho-toluidine	lb.	.20 — .25
Para-amidophenol, base	lb.	1.25 — 1.30
Para-amidophenol, HCl	lb.	1.35 — 1.40
Para-dichlorbenzene	lb.	.17 — 18
Paranitroaniline	lb.	.77 — .80
Para-nitrotoluene	lb.	.70 — .75
Para-phenylenediamine	lb.	1.60 — 1.65
Para-toluidine	lb.	1.10 — 1.15
Phthalic anhydride	lb.	.37 — 40
Phenol, U. S. P., drums	lb.	.12 — 16

Pyridine	gal.	1.75 —	2.75
Resorcinol, technical	lb.	1.30 —	1.35
Resorcinol, pure	lb.	1.85 —	2.00
Salicylic acid, tech., in bbls.	lb.	.18 —	.20
Salicylic acid, U. S. P.	lb.	.22 —	.23
Salol	lb.	.80 —	.82
Solvent naphtha, water-white, in drums, 100 gal.	gal.	.25 —	.28
Solvent naphtha, crude, heavy, in drums, 100 gal.	gal.	.12 —	.14
Sulphanilic acid, crude	lb.	.26 —	.28
Toluidine	lb.	1.20 —	1.30
Toluidine, mixed	lb.	.32 —	.38
Toluene, in tank cars	gal.	.25 —	.28
Toluene, in drums	gal.	.30 —	.35
Xylidines, drums, 100 gal.	lb.	.40 —	.45
Xylene, pure, in drums	gal.	.40 —	.45
Xylene, pure, in tank cars	gal.	.45 —	
Xylene, commercial, in drums, 100 gal.	gal.	.33 —	.35
Xylene, commercial, in tank cars	gal.	.30 —	....

Waxes

Stearic Acid, single pressed	lb.	8½—	9
Stearic Acid, double pressed	lb.	9¼—	9½
Stearic Acid, triple pressed	lb.	10¼—	10½

All other prices remain quotably unchanged.

Naval Stores

All prices are f.o.b. New York unless otherwise stated, and are based on carload lots. The oils in 50-gal. bbls., gross weight, 500 lb.

Rosin B-D, bbl.	280 lb.	$5.40 —	5.45
Rosin E-I	280 lb.	5.50 —	5.55
Rosin K-N	280 lb.	6.15 —	6.90
Rosin W. G.-W. W.	280 lb.	7.00 —	7.25
Wood rosin, bbl.	280 lb.	6.25 —	.....
Spirits of turpentine	gal.	91½ —	.....

Industrial

Financial, Construction and Manufacturers' News

Construction and Operation

Arkansas

ASHDOWN—The new company being organized by A. D. Banks, Little Rock, Ark., and associates, to operate a cement mill in the White Cliffs section, has concluded negotiations with the Ashdown Chamber of Commerce for the construction of a road to the property and for other work incidental to the establishment of the plant. Construction will be commenced at once, and equipment orders placed. In addition to the cement mill the company will also establish a plant for the manufacture of fertilizer products and whiting. The new organization will operate with a capital of $1,000,000.

California

ALAMEDA—The Direct Steel Process Co., San José, Cal., with experimental plant at Alameda, has preliminary plans under way for the construction of a new steel-manufacturing plant in the vicinity of San Francisco, and is negotiating with the Chamber of Commerce at the latter place for a suitable site. H. Bardue, vice-president and general manager, is in charge.

TORRENCE—Officials of the John E. Thropp's Sons Co., Lewis St., Trenton, N. J., manufacturer of rubber mill machinery, etc., have acquired the local plant of the Hendrie Rubber Co., and will organize a new company under the name of the Hendrie Rubber Tire Co. to operate the Torrence works for the manufacture of automobile tires, tubes and other rubber products. The new company will have a capital of $200,000, and will equip the plant for an initial daily capacity of about 350 tires and 200 tubes. Thomas H. Thropp is president and general manager; John E. Thropp, secretary; and William Baker, treasurer. The last noted will take up a residence in southern California, and will be in charge of operations at the plant.

NAPA—The Pacific Portland Cement Co. will discontinue operations at its mills at Napa Junction, near Napa, and the plant will be dismantled. It is proposed to remove the machinery to a new mill site.

Connecticut

NEW MILFORD—The New England Lime Co., Danbury, Conn., has awarded a contract to the Berlin Bridge Co., Berlin, Conn., for the construction of three 1-story buildings at New Milford, to replace its works recently destroyed by fire, with loss approximating $125,000. The new buildings will be 30 x 300 ft., 40 x 200 ft. and 25 x 75 ft., and with machinery will cost about the amount of fire loss. A number of other buildings will be erected at a later date. E. C. Grinning is president.

DANBURY—Fire, Feb. 3, destroyed a portion of the plant of the Beaverbrook Paper Mills, Inc., with loss estimated at about $125,000, including equipment.

NEW HAVEN—The Seamless Rubber Co., Hallock Ave., manufacturer of small rubber goods, has awarded a contract to Sullivan & McKeown, New Haven, for the construction of its proposed 1-story and basement addition, 140 x 160 ft., with wing extension, 60 x 60 ft., estimated to cost about $100,000. It will be used for spraying and other branches of manufacture. R. W. Foote, 185 Church St., is architect.

Idaho

COEUR D'ALENE—Idaho Clays, Inc., recently organized with a capital of $500,000, is arranging for the erection of a new plant on local site for the manufacture of brick, sewer pipe, terra cotta and other burned clay products. The company is headed by Laurence A. Spear and William M. Colby, both of Spokane, Wash.

Kansas

WICHITA—The Derby Oil Co. has construction under way on a new local oil refinery, estimated to cost about $500,000, with machinery, and will place the plant in service at the earliest date possible.

Louisiana

MONROE—The Sterling Carbon Co., Sterlington, near Monroe, is planning for the rebuilding of the mechanical department at its works destroyed by fire, Jan. 11, with loss estimated at about $25,000.

AVONDALE—The Standard Oil Co. of Louisiana has acquired the local plant of the Export Oil Corp., totaling about 800 acres, with frontage on the Mississippi River, for a consideration said to be about $950,000. The plant comprises a number of buildings, pumping plant, pipe line, storage facilities approximating 790,000 bbl., and will be used by the new owner primarily for export trade.

Massachusetts

SPRINGFIELD—The Strathmore Paper Co. has commenced the erection of its proposed new plant addition at West Springfield, to be 2-story, brick and concrete, 25 x 65 ft. The Casper Ranger Construction Co., Holyoke, Mass., has the general contract.

Maryland

BALTIMORE—The Mineral Potash Co., 712 Equitable Bldg., is completing plans and will soon take bids for the erection of a new 1-story plant at Ilchester, Md., to be 50 x 150 ft., and estimated to cost about $50,000. Louis A. Hazard is president.

BALTIMORE—Gilpin, Langdon & Co., Inc., 300 West Lombard St., manufacturer of drugs, chemicals, etc., has filed plans for the erection of a 1-story factory, 65 x 211 ft., at Eagle and Smallwood Sts., estimated to cost about $40,000.

VIENNA—The Nanticoke Flour Mill, operated by R. H. Baumgartner, is planning for the immediate rebuilding of the portion of its plant, destroyed by fire, Jan. 26, with loss estimated at about $17,000.

BALTIMORE—The Water Board, City Hall, has authorized the immediate preparation of plans for the construction of a new filtration plant for the waterworks system at Montebello, comprising new settling basins, coagulating basins, filtration plant proper and filtered-water reservoirs, estimated to cost about $1,200,000. William A. Megraw is water engineer in charge.

Michigan

KALAMAZOO—The Kalamazoo Vegetable Parchment Co., has completed plans and will take bids early in March for the erection of a 2-story addition to its plant, 90 x 925 ft., estimated to cost about $400,000. It will consist of two complete machine units. Billingham & Cobb, Press Bldg., are architects. J. Kindleberger is president and general manager.

BAY CITY—The Wildman Rubber Co. is perfecting plans for the early completion of its new local plant, now in course of erection, to be used for the manufacture of tires and other rubber products. To provide sufficient funds for the project, the company has arranged for a stock issue of $5,000,000, and this will be used, in part, for buildings and equipment purchases. W. W. Wildman, formerly president of the Portage Rubber Co., is head of the company; C. R. Twynham is treasurer.

DETROIT—The Aetna Portland Cement Co., 412 Union Trust Bldg., has completed plans for the erection of the first unit of its new cement mill at Essexville, near Bay City, and will commence work at an early date. It is estimated to cost in excess of $500,000. Franklin R. Johnson is president, and O. J. Lingeman, secretary.

Missouri

JEFFERSON CITY—The Standard Crate & Filler Co., operating at the former local plant of the J. M. Hays Wood Products Co., has acquired property totaling about 50 acres as a site for a new plant for the manufacture of strawboard products. It will cost about $350,000 with machinery. Plans will be prepared at an early date. The company was organized recently with a capital of $350,000.

New Jersey

NEWARK—The Nickelsburg Brothers Co., Meadow St., manufacturer of leather, has filed plans for the erection of a 1-story addition, 50 x 100 ft., to cost about $12,000.

WOODSTOWN—The South Jersey Farmers' Exchange has tentative plans under consideration for the erection of a 1-story fertilizer works, 50 x 180 ft., to replace its plant recently destroyed by fire. A. B. Lippincott is in charge.

JERSEY CITY—Colgate & Co., 105 Hudson St., manufacturers of soaps, etc., have filed plans for the erection of an addition to their plant at 17-25 Grand St., to cost about $22,000.

New York

BOLIVAR—The Bolivar Refining Co. is planning for the erection of a new oil refinery on local site. An extensive oil storage plant will also be constructed. Charles A. Chapman is head.

OSWEGO—The local plant of the National Starch Co., of the Corn Products Refining Corp., 17 Battery Pl., New York, has been acquired by the Oswego Factories Corp., which will take possession on July 1. The new owner plans for the operation of the works.

BROOKLYN—Fire on Feb. 3 partly destroyed the three buildings at 61-65 Taaffe Pl., occupied by the Columbia Cement Co., Floradale Chemical Co. and the Eastern Bronze Wire Works, respectively, with loss estimated at close to $25,000, divided among the different companies.

Ohio

FOSTORIA — The Bellevue Rubber Co., Bellevue, O., H. B Skinner, president, is planning for extensions and improvements in its 2-story and basement plant at Fostoria.

Pennsylvania

LOCK HAVEN—Fire on Feb. 1 destroyed the main building at the plant of the American Aniline Products Co., with loss estimated at about $200,000.

MOUNT UNION—The plant of the Mount Union Tanning & Extract Co. has been acquired by Calvin Greene and associates, who will operate the property in the future. The factory heretofore has been devoted to the manufacture of sole leather.

HAZELHURST — Fire on Jan. 27 destroyed a portion of the local plant of the Interstate Window Glass Co., with loss estimated at about $125,000.

MOUNT HOLLY SPRINGS—Llewllyn A. Marr, 176 Federal St., Boston, Mass., and E. J McDonnell, associated paper manufacturers, have acquired the local plant of the Mount Holly Paper Mills Co. at a receiver's sale for a consideration stated as $55,000. The new owners plan to place the mill in service at an early date, giving employment to about 125 operatives.

Tennessee

CHATTANOOGA—The Crane Enameling Co., recently organized as a subsidiary of the Crane Co., 835 South Michigan Ave., Chicago, Ill., with capital of $1,500,000, has taken possession of the local plants of the Mutual Enameling Co. and the Cahill Iron Works, and will operate these plants for the manufacture of high-grade enamel ware. The new factory of the Mutual company in the Alton Park section will be used as the main plant unit, and the Cahill works on Chestnut St. will be used as a branch. When operating full the two plants will give employment to about 600 operatives. R. T. Crane, Jr., Chicago, is president.

Texas

HOUSTON—The Switzer-Parke Co., 105 Paige St., recently organized with a capital of $30,000, has awarded a contract for the erection of a new plant, totaling about 11,000 sq.ft. of floor space, to be equipped as an electroplating and enamel-baking works. It is planned to commence production at an early date. Willard M. Parke is president, and Homer E. Switzer, secretary-treasurer.

TERRELL—Fire on Jan. 27 destroyed a portion of the plant of the Terrell Cotton Oil & Refining Co., with loss estimated at close to $40,000.

West Virginia

BLUEFIELD — The Tri-State Chemical Co., Box 46, recently organized, is planning for the establishment of a local plant for the manufacture of special chemical powders for fire-extinguishing service. Edward Palmer is manager.

New Companies

THE ATLANTIC CHEMICAL MFG. CO., Atlantic ty, N. J., has been incorporated with a pital of $50,000, to manufacture chemicals d chemical byproducts. The incorporators e John A. G. Iden, Fred P. Steckel and ving P. Parsons, 33 Real Estate Bldg., lantic City.

THE IRONIZED YEAST CO., Atlanta, Ga., has en incorporated with a capital of $300,- 0, to manufacture yeast and kindred oducts. The incorporators are W. P. oodworth, Mark Bolding and R. G. ephens, all of Atlanta.

THE MARCO CHEMICAL CO., 501-2 Genesee ank Bldg., Flint, Mich., has been incor- rated with a capital of $10,000, to manu- cture chemicals, alkalis and affiliated oducts. The incorporators are Clyde ewman, Lee L. Martin and H. Martin.

THE EASTERN BRICK CO., New York, N. Y., as been incorporated under Delaware laws ith capital of $2,000,000, to manufacture ick, tile and other burned clay products. he company is represented by the United tates Corporation Co., 65 Cedar St., New ork.

THE OSWEGO FALLS CORP., Fulton, N. Y., as been incorporated with a capital of 2,500,000, to manufacture pulp and paper oducts. The company will comprise a erger of the Oswego Falls Pulp & Paper o., Fulton; the Skaneateles Paper Co., kaneateles, N. Y.; and the Sealright Co., this same district. The incorporators are . L. Paddock, F. G. Weeks and C. W. ooke. Headquarters will be at the plant the Oswego Falls Pulp & Paper Co., ulton.

THE HORMONE CHEMICAL CORP., East range, N. J., has been incorporated with a pital of $50,000, to manufacture chemicals nd chemical byproducts. The incorpora- rs are Arthur L. Walsh, Joseph F. McCoy nd Harold L. Lyman, 331 Main St., East range.

THE JOSE OIL CO., Los Angeles, Cal., has en incorporated with a capital of $200,- 00, to manufacture petroleum products. he incorporators are H. A. Bordeen, J. aul Getty and Russell Avery. The com- any is represented by Anderson & Ander- n, 1112 Black Bldg., Los Angeles.

E. W. JEFFRESS, INC., Detroit, Mich., has en incorporated with a capital of $10,000, manufacture chemicals and affiliated roducts. The incorporators are J. G. Ham- len, Jr., E. W. and M. M. Jeffress, 1350 efferson Ave., East, Detroit.

THE ABBOTT INK CO., Room 1400, 69 West Vashington St., Chicago, Ill., has been in- orporated with a capital of $9,000, to anufacture inks and kindred specialties. he incorporators are Thuriow W. Brewer, icholas F. Roeder and Francis B. Regan.

THE FARMERS' FERTILIZER CO., Sumter, . C., has been incorporated with a capital f $10,000, to manufacture fertilizer prod- cts. H J. Harby is president; H. W. larby, vice-president; and J. H. Guthrle, ecretary, all of Sumter.

THE INGERSOLL PRODUCTS CO., Newark . J., has been incorporated with 500 shares f stock, no par value, to manufacture oil ompounds, etc. The incorporators are J. S. eichliter, H. T. Maloney and Palmer radner, Kinney Bldg., Newark.

THE EDDYLITE SPARK PLUG CO., Buffalo, . Y. has been incorporated with a cap- tal of $100,000, to manufacture porcelain park plugs and affiliated products. The ncorporators are W. F. Feser, L. J. and . B. Eddy. The company is represented y J. H. Ryan, attorney, Olean, N. Y.

THE INTERNATIONAL CHEMICAL PRODUCTS o., San Fernando, Cal., has been incor- orated with a capital of $250,000, to manu- acture chemicals and chemical byproducts. he incorporators are H. J. Poppelman, rthur G. and Bernard A. Munn, all of an Fernando.

THE DAMASCUS STEEL PRODUCTS CORP., 500 Fourteenth Ave., Rockford, Ill., has een incorporated with a capital of $50,000, o manufacture steel specialties. The in- orporators are C. F. Maitland, C. P. Two- ney and J. R. Hughes.

THE SUNFLOWER OIL CO., Shreveport, La., as been incorporated with a capital of 120,000, to manufacture petroleum prod- cts. A. W. Baird, Sr., is president; John B. Hutchinson, vice-president; and A. W. Baird, Jr., secretary and treasurer, all of Shreveport.

THE LA SALLE PAPER CO., South Bend, nd., has been incorporated with a capital of $250,000, to manufacture paper and pulp roducts. The incorporators are E. O. and Claude E. Nicely, and John G. Yeagley, all of South Bend.

THE GOODCHILD GLASS MFG. CO., Haw- thorne, N. J., has been incorporated with a capital of 2,500 shares of stock, no par value, to manufacture glassware products. The incorporators are Walter Goodchild, Walter Hohenhausen and Harry Grundy, 177 Washington Ave., Hawthorne.

THE PORT UNION BRASS FOUNDRY CO., New York, N. Y., has been incorporated with a capital of $30,000, to manufacture brass, bronze and other metal castings. The incorporators are H. V. Bebarfald, B. F. Vineburg and P. E. Uhr. The company is represented by Manken Bros., 206 Broad- way, New York.

THE MARYLAND SMELTING & REFINING CO., INC., 23 West Antietam St., Hagers- town, Md., has been incorporated with a capital of $35,000, to manufacture refined metals, operate a smelting works, etc. The incorporators are Henry H. Keedy, Jr., Leon R. Yourtee and John D. Keith.

THE AMERICAN LEATHER GOODS CO., New- ark, N. J., has been incorporated with a capital of $100,000, to manufacture leather products. The incorporators are Abraham Danzig, Edward Faragasso and John Par- lante. The company is represented by Philip J. Schotland, 9 Clinton St., Newark.

THE NATIONAL INK CO., Baltimore, Md., has been incorporated under Delaware laws with capital of $100,000, to manufacture inks, chemicals and kindred products. The incorporators are James L. Bell, Harry D. Howell and Harry A. Kendall, Baltimore. The company is represented by the Colo- nial Charter Co., Ford Bldg., Wilmington, Del.

THE SUMMER RUBBER CO., Boston, Mass., has been incorporated with a capital of $5,000, to manufacture rubber products. John Woolf is president, and Victor Miller, 53 Strathmore Road, Brookline, Mass., treasurer.

THE ARCHER PHOSPHATE DEVELOPMENT CO., Archer, Fla., has been incorporated with a capital of $75,000, to manufacture phosphate and kindred products for fertil- izer and other service. W. F. Walker is president; S. G. Moyers, vice-president; and E. N. Morrow, secretary and treasurer, all of Archer.

THE HART LEATHER FINISH CO., 1046 West Division St., Chicago, Ill., has been incorporated with a capital of $10,000, to manufacture finishes and compounds for leather and kindred products. The incor- porators are James M. Hart, William B. Carroll and Edward S. Cummings.

THE SMITHFIELD OIL CO., Wilmington, Del., has been incorporated under state laws with capital of $100,000, to manufac- ture petroleum products. The company is represented by the Capital Trust Co. of Delaware, Dover, Del.

ZIEGEL, EISMAN & CO., Newark, N. J., has been incorporated with a capital of $1,000,- 000, to manufacture leather products. The incorporators are M. and H. Seymour Eis- man, and Leo Goldsmith, 99 Frelinghuysen Ave., Newark.

THE FRANKFORD PAPER BOX CO., Phila- delphia, Pa., is being organized by Wil- liam J. Zimmerman, Jr., George E. Beck and J. Edward Linck, to manufacture paper products. Application for a state charter will be made at once. The company is represented by R. P. Frank Maxwell, 1919 East Chelten St., Philadelphia.

THE TRAVIS COTTONSEED PRODUCTS CO., Austin, Tex., has been incorporated with a capital of $50,000, to manufacture cotton- seed oils. The incorporators are E. H. Perry, D. G. Reed and Oscar Robinson, all of Austin.

ZURA, INC., 608 South Dearborn St., Chi- cago, Ill., has been incorporated with a capital of $50,000, to manufacture chemi- cals and affiliated products. The incorpora- tors are Joseph B. Duncan, E. C. Auld and William B. Ziff.

THE UTAH SHALE PROCESS CORP., Denver, Col., has been incorporated under Dela- ware laws with capital of $1,000,000, to manufacture coal-tar products and affili- ated specialties. The incorporators are Frederick M. Browning, Denver; William S. Pitts, and David C. Dodge, New York. The company is represented by the Colonial Charter Co, Ford Bldg., Wilmington, Del.

THE MUTUAL OIL PRODUCTS CO., Newark, N. J., has been incorporated with a capital of $100,000, to manufacture refined oil products. The incorporators are Harvey C. Harrison, Clarence L. Powell and Rob- ert Rogers, 17 Margaretta St., Newark.

THE PINEVILLE PAINT & VARNISH CO., Pineville, Ky., has been incorporated with a capital of $20,000, to manufacture paints, varnishes, etc. The incorporators are H. M. Ernst, W. N. Payne and W. L. Long, all of Pineville.

Capital Increases, Etc.

THE INDIAHOMA REFINING CO., East St. Louis, Ill., operating a local oil refinery and with similar plant at Okmulgee, Okla., has disposed of a bond issue of $1,750,000, the proceeds to be used for financing, general operations, etc. Elmer E. Schock is presi- dent.

THE AMERICAN ART CLAY CO., Indian- apolis, Ind., has filed notice of dissolution under state laws.

THE WISCONSIN CHEMICAL CO., Detroit, Mich., capitalized at $100,000, has filed notice of dissolution.

THE HOOKER ELECTROCHEMICAL CO., Niagara Falls, N. Y., has filed notice of a mortgage on its property taken by the Equitable Trust Co., New York, N. Y., totaling $12,500,000.

THE GENERAL LINSEED OIL CO., 1637 West Roosevelt St., Chicago, Ill., has filed notice of change of name to the General Paint & Varnish Co., at the same time in- creasing its capital from $10,000 to $50,000.

A. Parker Nevin has been appointed re- ceiver for the EL SALVADOR SILVER MINES CO., 11 Pine St., New York, N. Y., operat- ing properties in San Salvador. Edward D. Dowling is president.

THE COLUMBUS FOUNDRY CO., Columbus, Ga., and the W. L. LEMLY FOUNDRY CO., Bessemer, Ala., have been merged under the latter name, and the plant of the first noted company will be removed to Bessemer.

THE MAINE PULP & PAPER CO., D. S. Morgan Bldg., Buffalo, N. Y., with pulp and paper mills in Maine, has filed a volun- tary petition in bankruptcy, listing liabili- ties of $420,391.96, and assets of $454,021.09. Andrew Krieger is president.

Stockholders of the KELLEY TIRE & RUB- BER CO., New Haven, Conn., manufacturer of tires and other rubber goods, with local plant, are arranging for a reorganization, abolishing the receivership under which operations have been conducted for some time.

The flour mill property of the C. A. GAMBRILL MFG. CO., Ellicott City, Md., will be offered for sale by the trustees in bank- ruptcy, Herman A. Tingley and John B. H. Dunn, 110 Commerce St., Baltimore, Md., on Feb. 20.

Manufacturers' Catalogs

THE QUIGLEY FURNACE SPECIALTIES CO., New York, has recently issued Bull. 51 on the method of applying successful boiler setting patches. Another bulletin presents information, with illustrations, regarding re- fractory linings and the use of Hytempite in power plant work, as well as its uses in connection with Carbosand for baffles, patching boiler settings, etc. Pages 18 and 19 give some information on the uses of Insulbrix and show comparative heat losses of uninsulated and insulated walls. This company also calls attention to Bull. 52, describing the use of Hytempite in making one-piece baffles of refractory concrete. This bulletin is well illustrated and tells an interesting story of the experience of a large Brooklyn concern.

THE NORTON CO., Worcester, Mass., has issued two new bulletins: one on "Metal Polishing" and the other on "Factors Af- fecting Grinding Wheel Selection."

THE CAREY CO., Pittsburgh, Pa., has issued a circular describing its newly patented carboy inclinator, which is claimed to be a much more economical way of handling acids and other chemicals, when received in carboys.

ROBERT L. STILLSON CO., New York has published an attractive book on "Out- spinning the Spider, the Story of Wire and Wire Rope," by John Kimberly Mum- ford. It tells the history of wire-rope making in this country from the beginning of the industry in 1840, and relates the romance of the Brooklyn Bridge; of the wire rope barrage laid down in the English Channel during the late war; and other interesting engineering achievements.

INGERSOLL-RAND CO., New York, has issued a catalog on "Steam Condensing Plants" which is a reprint of Paul Bancel's paper read before the Baltimore Section of the American Society of Mechanical Engi- neers, May 16, 1921.

WILLIAMS TOOL CORP., Erie, Pa., calls attention to its latest booklet entitled "Don't Let It Happen to You." This book- let was written for the man who owns or

operates a power pipe machine, and represents an endeavor on the company's part to educate and instruct all operators of power pipe machines for better threads and greater production. Copies will gladly be sent on request.

THE CUTLER-HAMMER MFG. CO., Milwaukee, has issued a new bulletin, No. 2039, covering the New Thomas Calorimeter, which records total heating values of gas graphically.

THE GENERAL ENGINEERING CO., Salt Lake City, Utah, has issued a new metallurgical bulletin describing its facilities for investigations in ore treatment. The pamphlet is illustrated with representative mills, design and construction by the company. It contains also considerable general information on metal statistics, cost of mill operations, cost of steam and electric power, etc. The company has made an unusual and successful effort to produce a bulletin of exceptional value.

THE AMERICAN STEAM GAUGE & VALVE MFG. CO., Boston, Mass., in an 8-page folder illustrates and describes the new American recording thermometer, which has been designed after years of experimental work and field tests. These instruments are designed to record accurate temperatures and to meet every industrial need and can be furnished for any desired temperature range up to 1,000 deg. F.

BEACH-RUSS CO., New York City announces a new 4-page bulletin, No. 27, on Rotary Pumps.

THE ABBE ENGINEERING CO., New York City has issued Bull. 18 on its products, which include pebble mills, ball mills, tube mills, pulverizing machinery, bolting cloth, rotary cutters, disintegrators, mixers, etc.

THE GOULDS MFG. CO., Seneca Falls, N. Y., is distributing Bull. 123 descriptive of the newest addition to its pump line—the Goulds steam turbine-driven centrifugal pump.

THE DURIRON CO., INC., Dayton, O., calls attention to Bulletin 127, illustrating and describing the Duriron-Merco lubricated plug cock, which should be of interest where corrosion must be controlled in pipe lines. In Bulletin 126-A this company treats sanitary drain pipe and fittings.

THE INDUSTRIAL WORKS, Bay City, Mich., has published Catalog 113, illustrating and describing the Type BC "Industrial crawling tractor crane, which has a capacity of 20,000 lb. and can be equipped to handle a hook and block, grab bucket, drag-scraper bucket, wood grapple, electric-lifting magnet shovel dipper, and pile driver leads with drop hammer. This crane should prove useful to road contractors, lumber and coal dealers, gravel, sand and stone producers, foundries, railroad reclamation and storage yards, and moderate-size manufacturing plants.

THE ATLAS VALVE CO., Newark, N. J., has just published Catalog 21, on Atlas, Ideal and Victor reducing valves, pump governors, pressure regulators, hot water tank regulators, control valves and damper regulators. This 20-page catalog illustrates, describes and lists all sizes and gives prices. A copy will be sent free on request.

ALLIS-CHALMERS MFG. CO., Milwaukee, Wis., calls attention to Bulletin 1108, on Power Transformers. This attractive 32-page booklet illustrates and describes power transformers.

STROMBERG ELECTRIC CO., Chicago, Ill., has issued a bulletin describing its process timing and signaling instruments. This instrument has been developed as an accurate means of automatically operating a signal at the end of a predetermined time, to announce the completion of a process or operation, and has a very broad field of application.

THE UNION MINING CO., INC., Mount Savage, Md., has issued Catalog H, on Firebrick. It contains 150 pages, 4 x 6½ in., and describes the company's products and also gives general information.

SKINNER, SHERMAN & ESSELEN, Boston, Mass., have issued a booklet entitled "Mr. Banker, Meet Old Man Chemistry," by James H. Collins. It is an interesting booklet, which has been published in the endeavor to give publicity to chemical matters. Copies will be sent on request.

THE VACUUM OIL CO., New York, has issued two educational publications: One on "Oil Engines" and the other on "Stationary Steam Engines." In the first-mentioned booklet the principle is described as well as the construction, operation, cooling, fuel, methods of lubrication, lubricating oil and deposits. The second booklet treats reciprocating steam engineers and boiler plant and steam production. Interested individuals will be furnished copies on request.

THE OILGEAR CO., Milwaukee, Wis., announces the publication of Bull. 2, on Oilgear variable speed hydraulic power transmissions, and Bull. 6, on the Oilgear Control Pump.

THE CUTTER CO., Philadelphia, Pa., has issued a bulletin on U-re-lite, which is an I-T-E circuit breaker inclosed in a specially constructed steel case from the front of which projects a convenient operating handle.

THE BRISTOL CO., Waterbury, Conn., has published Catalog 1501, descriptive of its round chart recording electrical instruments, including voltmeters, ammeters and wattmeters, which can be furnished in the strip chart type.

New Publications

NEW BUREAU OF MINES PUBLICATIONS: Eleventh Annual Report of the Director of the Bureau of Mines to the Secretary of the Interior for the fiscal year ended June 30, 1922; Bull. 187, Treatment of the Tungsten Ores of Boulder County, Col., by J. P. Bonardi and J. C. Williams; Tech. Paper 248, Gas Masks for Gases Met in Fighting Fires, by Arno C. Fieldner, Sidney H. Katz and Selwyne P. Kinney; Tech. Paper 249, The Determination of Oxides of Nitrogen, by V. C. Allison, W. L. Parker and C. W. Jones; Tech. Paper 284, Coal and Coke Mixtures as Water-Gas Generator Fuel, by W. W. Odell.

NEW BUREAU OF STANDARDS PUBLICATIONS: Circular 38, The Testing of Rubber Goods; Circular 113, Structure and Related Properties of Metals; Circular 115, Recommended Specifications for Pneumatic Tires, Solid Tires and Inner Tubes; Circular 117, Recommended Specification for Interior Varnish; Circular 118, Recommended Specification for Limestone, Quicklime and Hydrated Lime for Use in the Manufacture of Glass; Sci. Paper 419, The Production of Liquid Air on a Laboratory Scale, by J. W. Cook; Sci. Paper 420, Specific Volume of Liquid Ammonia, by C. S. Cragoe and D. R. Harper; Tech. Paper 193, Design of Atmospheric Gas Burners, by Walter M. Berry, I. V. Brumbaugh, G. F. Moulton and G. B. Shawn; Tech. Paper 196, High Fire Porcelain Glazes, by H. H. Sortwell; Tech. Paper 197, Cementing Qualities of the Calcium Aluminates, by P. H. Bates; Tech. Paper 199, Method for Precision Test of Large Capacity Scales, by C. A. Briggs and E. D. Gordon.

NEW U. S. GEOLOGICAL SURVEY PUBLICATIONS: I: 8, Antimony in 1920, by Frank C. Schrader (Mineral Resources of the U. S., 1920, Part I), published Oct. 27, 1921; I: 9, Lead in 1920, by C. E. Siebenthal and A. Stoll (Mineral Resources of the U. S., 1920, Part I), published Oct. 14, 1921; I: 10, Secondary Metals in 1920, by J. P. Dunlop (Mineral Resources of the U. S., 1920, Part I), published Nov. 11, 1921; I: 12, Gold, Silver, Copper and Lead in South Dakota and Wyoming in 1920, by C. W. Henderson (Mineral Resources of the U. S., 1920, Part I), published Nov. 3, 1921; I: 13, Gold, Silver, Copper, Lead and Zinc in California and Oregon in 1920, by Charles G. Yale (Mineral Resources of the U. S., 1920, Part 1), published Nov. 25, 1921; I: 15, Zinc in 1920, by C. E. Siebenthal and A. Stoll (Mineral Resources of the U. S., 1920, Part I), published Dec. 19, 1921; I: 23, Iron Ore, Pig Iron and Steel in 1919, by Ernest F. Burchard (Mineral Resources of the U. S., 1919, Part I), published Oct. 14, 1921; I: 24, Zinc in 1919, by C. E. Siebenthal and A. Stoll (Mineral Resources of the U. S., 1919, Part I), published Oct. 13, 1921; I: 25, Gold and Silver in 1919, by J. P. Dunlop (Mineral Resources of the U. S., 1919, Part I), published Oct. 31, 1921; I: 26, Cobalt, Molybdenum, Nickel, Tantalum, Titanium, Tungsten, Radium, Uranium and Vanadium in 1919, by Frank L. Hess (Mineral Resources of the U. S., 1919, Part I), published Nov. 10, 1921; II: 13, Potash in 1920, by M. R. Nourse (Mineral Resources of the U. S., 1920, Part II), published Oct. 4, 1921; II: 14, Sodium Compounds in 1920, by Roger C. Wells (Mineral Resources of the U. S., 1920, Part II), published Sept. 30, 1921; II: 15, Slate in 1920, by G. F. Loughlin and A. T. Coons (Mineral Resources of the U. S., 1920, Part II), published Oct. 12, 1921; II: 16, Carbon Black Produced From Natural Gas in 1920, by E. G. Sievers (Mineral Resources of the U. S., 1920, Part II), published Oct. 13, 1921; II: 17, Silica in 1920, by L. M. Beach (Mineral Resources of the U. S., 1920, Part II), published Oct. 11, 1921; II: 18, Feldspar in 1920, by L. M. Beach (Mineral Resources of the U. S., 1920, Part II), published Oct. 29, 1921; II: 19, Abrasive Materials in 1920, by L. M. Beach and A. T. Coons (Mineral Resources of the U. S., 1920, Part II), published Oct. 28, 1921; II: 20, Mineral Waters in 1920, by W. D. Collins (Mineral Resources of the U. S., 1920, Part II), published Oct. 29, 1921; II: 21, Sand and Gravel in 1920, by L. M. Beach (Mineral Resources of the U. S., 1920, Part II), published Nov. 5, 1921; II: 22, Lime in 1920, by G. F. Loughlin and A. T. Coons (Mineral Resources of the U. S., 1920, Part II), published Nov. 3, 1921; II: 23, Barytes and Barium Products in 1920, by George W. Stose (Mineral Resources of the U. S., 1920, Part II), published Dec. 6, 1921; II: 29, Abrasive Materials in 1919, by L. M. Beach and A. T. Coons (Mineral Resources of the U. S., 1919, Part II), published Sept. 16, 1921; II: 31, Lime in 1919, by G. F. Loughlin and A. T. Coons (Mineral Resources of the U. S., 1919, Part II), published Oct. 6, 1921; II: 32, Stone in 1919, by G. F. Loughlin and A. T. Coons (Mineral Resources of the U. S., 1919, Part II), published Oct. 18, 1921; II: 34, Natural-Gas Gasoline in 1919, by E. G. Sievers (Mineral Resources of the U. S., 1919, Part II), published Dec. 7, 1921.

THE UNIVERSITY OF ILLINOIS has issued Bulletin 125, on "The Distribution of the Forms of Sulphur in the Coal Bed," by H. F. Yancey and Thomas Fraser.

THE NATIONAL RESEARCH COUNCIL has issued pamphlet No. 15, on "Researches on Modern Brisant Nitro Explosives," by C. F. vanDuin and B. C. Roeters vanLennep, and No. 23, on "American Research Chemicals," by Clarence J. West.

THE HERCULES POWDER CO., Wilmington, Del., has reprinted in pamphlet form N. S. Greensfelder's article on "Explosives' Part in China Making," which appeared in the *Hercules Mixer* for January, 1922.

"REZISTAL STEEL" is the title of a pamphlet by Charles Morris which is being issued with the compliments of the Crucible Steel Co. of America, New York.

Coming Meetings and Events

AMERICAN CERAMIC SOCIETY will hold its twenty-fourth annual meeting at St. Louis, Feb. 27 to March 3, 1922.

AMERICAN CHEMICAL SOCIETY will hold its spring meeting at Birmingham, Ala., April 4 to 7, 1922.

AMERICAN ELECTROCHEMICAL SOCIETY will hold its spring meeting in Baltimore, April 27, 28 and 29, 1922. Headquarters will be at the Emerson Hotel.

AMERICAN FOUNDRYMEN'S ASSOCIATION will hold its next convention and exhibit at Rochester, N. Y., during the week of June 5, 1922. Meetings will be held in the spring instead of in the fall as heretofore.

AMERICAN INSTITUTE OF MINING AND METALLURGICAL ENGINEERS will hold its spring meeting in New York the week of Feb. 20, 1922.

AMERICAN SOCIETY FOR STEEL TREATING will hold a sectional meeting, Friday, March 3, at the Hotel McAlpin, New York City.

AMERICAN SOCIETY FOR TESTING MATERIALS will hold its twenty-fifth annual meeting June 26 to July 1, at Atlantic City, N. J. Headquarters will be at the Chalfonte-Haddon Hall Hotel.

INTERNATIONAL UNION OF PURE AND APPLIED CHEMISTRY will hold a meeting at Lyons, France, June 27 to 30.

IRON AND STEEL INSTITUTE (British) will hold its annual meeting on May 4 and 5 at the House of the Institution of Civil Engineers, Great George St., S. W., 1, London.

NEW JERSEY CHEMICAL SOCIETY holds a meeting at Stetters Restaurant, 842 Broad St., Newark, N. J., the second Monday of every month.

NORTHWEST MINING ASSOCIATION is holding a convention in the Chamber of Commerce Bldg., Spokane, Wash., Feb. 14 to 18.

STAMFORD CHEMICAL SOCIETY, Stamford, Conn., holds a meeting in the lecture room of the local high school on the fourth Monday of each month, except June, July, August and September.

The following meetings are scheduled to be held in Rumford Hall, the Chemists' Club, New York: March 10—American Chemical Society, Nichols Medal; March 24—Society of Chemical Industry, regular meeting; April 21—Society of Chemical Industry (in charge), American Electrochemical Society, Société de Chimie Industrielle, American Chemical Society, joint meeting; May 5—American Chemical Society, regular meeting; May 12—Société de Chimie Industrielle (in charge), American Chemical Society, Society of Chemical Industry, American Electrochemical Society, joint meeting; May 19—Society of Chemical Industry, regular meeting; June 9—American Chemical Society, regular meeting.

The Trade Association's Relation to Industry

WHILE the announcement of the government's attitude toward the trade association leaves much to be desired, it is nevertheless a distinctly forward step in our industrial program. It relieves business to a great extent of the burden of uncertainty which had been heaped upon its shoulders by the Supreme Court decision last December in the case against the Hardwood Lumber Manufacturers' Association. The outcome of that case has affected the whole network of industries, for the open price association or "open competition plan," which it threatened, had become thoroughly established in many basic industries. Consumers and distributors as well as producers had felt its effect. Now comes the word that the plan, with certain definite limitations and under the very close supervision of the Department of Commerce, can be continued.

Secretary HOOVER, whose recent work with that department has been largely based on the establishment of a comprehensive statistical service as well as an intimate contact with all trade agencies, has endeavored to obtain a public statement from the Department of Justice from which business might derive final and official legal guidance. The fear that such a statement might be used in the courts against the government, however, has no doubt actuated the Attorney-General in his desire to confine his opinion to the form in which it is now made public—namely, as an informal interdepartmental inquiry defining the policy to be pursued by the Commerce Department in its future relations with business.

Of all the many activities of the trade associations, those connected with the statistical services have involved questions of perhaps the most serious and complex legal character. The decision in the case of the hardwood manufacturers, it will be recalled, was not a condemnation of the gathering and dissemination of statistics *per se*, nor did it prevent the recipient from using such statistical information as a basis for his future business transactions. It is only when the statistics are collected by some centralized authority and so interpreted by him as to evoke or otherwise result in combined action in restricted production, price fixing or some other equally unlawful activity that the government has held the procedure to be in restraint of trade and therefore a violation of the Sherman act. The Secretary put the case well and forcefully when he said, "The fact that the minority may be known to violate given laws does not establish a principle that the primary means, lawful in itself, which they have adopted for the purpose of performing the unlawful acts, should be entirely abolished and its use forbidden to law-abiding citizens." Thus the revolver in the hands of the criminal may be used illegally, but there are many good reasons why the revolver should not be legislated out of existence. The reckless automobile driver is a dangerous law-breaker, but certainly we are not justified in abolishing the automobile simply because he chooses to use it illegally. Those users of the open competition plan who in the past have offended the majesty of the law should be made to suffer, but the plan when properly conducted can be made a legitimate service to business.

The inquiries of Secretary HOOVER, reproduced on another page of this issue, outline a plan by which the Department of Commerce is to become a general clearing house for statistical information from all trade associations. Through him these data are then to be transmitted to the general public. Thus buyer and seller, producer and consumer, receive the same information regarding industrial conditions and are able to base their business judgment on the same facts and figures. Another plan which has received serious consideration in many quarters has been the proposal to use the industrial press as the medium for the dissemination of this information. One of our readers, whose letter we are glad to publish under "Readers' Views and Comments," has outlined a definite form of co-operation between the association secretary and the editor of the business paper. Such an arrangement naturally meets with the approval of the technical magazine interested in furthering the best interests of the industry it serves.

There can be no question about the legality of many of the activities which are discussed in the Hoover-Daugherty correspondence. The value of constructive endeavor such as the handling of educational and welfare work, the elimination of wasteful practices, co-operative advertising, and strengthening foreign and domestic trade, is not to be questioned. An investigation recently made by the Chamber of Commerce of the United States has resulted in a list of almost eighty different activities which in the past have absorbed the attention of the various trade and business organizations. Some of these, to be sure, have been discontinued because of the decision, but undoubtedly there are many ways in which associations can benefit industry.

The chief good arising from the government's statement is the official recognition of the trade association as an essential element of modern business. We can now be sure that we are not going to revert to the days when business was characterized by ignorant, wasteful competition, price cutting, over- and underproduction, and periodic labor shortages followed by unemployment. The officers and members of trade associations must see that illegal practices are abolished and must do their share in dispelling the suspicion that has surrounded their activities. And, finally, by accepting the government's offer of co-operation, they can pave the way to a better and more intelligent service to industry and to the general public.

When Does an Employment Contract Terminate?

HOW much of a man's brain does the law allow him enforceably to sign away through the necessities of making a living? How far do enactments against peonage protect a technical man from the operation of contracts terminable at the will of his employer, but with provisions stipulating duties after termination?

The questions above have an added pertinence today when so many technically trained men, precipitately let go during the past year at the first pinch of adversity, are now put to the necessity of bargaining their training and intelligence for the means of a living. Old contracts that meant bread and butter yesterday may be the means of denying it today—at least in the profession chosen. A man's experience and training in this world, barring the possession of wealth, are the capital whereon he must seek returns for a livelihood. The practice of some large technical corporations which extort, as the price of employment, the signing of a contract forever limiting a man's usefulness outside their own factory walls is open to serious discussion in the light of present conditions. Some protection is undoubtedly due the employer of confidential technicians who labor and create for the advantage of that employer; but should that protection be given gratis or exacted as the price of a job? If it is of value should it not be paid for, either by some assurance of stability of position or, at least, by some more valuable consideration than a month's notice?

Incidents such as a recent one wherein a large corporation has sought by the threat of legal prosecution to prevent a research engineer, formerly in its employ and recently released for economy's sake, from following his calling in his own chosen field demand attention that will forever prevent a repetition of the attempt. In the instance cited a signed contract is now invoked and exhibited which, strictly interpreted, would make the effort successful. Just how binding are unjust provisions of an employment contract? An executed instrument that specifies duties after employment has ceased may be the means of blacklist and boycott, unless the unfortunate signer seeks a different field. Unfitted, possibly, for anything else; his whole life training rendered useless; a corporation that battens on brains can tell him he may starve—if that is the only alternative.

The average man in need of employment is in no position to dictate or object to terms in the contract offered him. In a sense he is coerced by circumstances into signing, and the measure of his necessity is the degree of coercion practiced. Just how binding, morally or legally, is an instrument in which the element of coercion enters?

But a contract must allow the right to discharge. In technical employment, if the employee is guilty of violating the confidence reposed in him, the right to discharge is not sufficient. It should be strengthened, and by mutual recognition, by the assurance of prosecution and punishment. Where no culpability enters in, however, a mutual agreement should proclaim and recognize a mutual responsibility. Necessities which lead to severing the ties of such an agreement should terminate the responsibility as well. When released through no fault of their own, technical men should be protected from every danger of blacklist, boycott or attempted curtailment of their usefulness to themselves or society through the operation of contracts signed while seeking employment. A court precedent should establish that a contract terminated in one particular is thereby terminated in every other.

Are there other injuries being worked today through hold-over duties and obligations of terminated contracts? A federal investigation of the employment contracts offered technical men by those corporations entering into interstate commerce might throw interesting light on the subject.

Information for Business Guidance

A FRIEND of ours raises the question whether the average business man who directs the affairs of commercial enterprises has a clear concept of all the information necessary for guidance in making business decisions. He doubts not that business men, as a rule, gather a vast amount of information, but he has serious misgivings as to whether they recognize the essentials and do not burden and confuse their minds with matters that have no real bearing on their problems.

We know quite well that the typical business man is strong on efficiency. He is great for requiring his superintendents and foremen to introduce efficient methods in the factory. He seeks efficiency in the physical manipulation of his affairs, requiring, for instance, that the papers coming to his desk be placed on a certain spot, and providing a series of baskets for the outgoing stuff. Nothing must come to his desk that does not belong there. The underling is reprimanded if he brings something to him that should be handled by SMITH or JONES, and is reprimanded likewise if he places before SMITH or JONES a matter that should be settled by the boss himself.

It is a question of efficiency in mental operations. Does our business man take equal pains to see that information essential to good business judgment is placed in an orderly manner in his mind, while unnecessary matters are kept out so that they do not clutter his mental desk? That is quite doubtful. Men of affairs are often moved by example rather than by study of underlying conditions. The point is well illustrated by boards of directors. There are directors who might perhaps be called peripatetic for want of a better term. They belong to numerous boards. When they see a certain action taken at one board meeting, whether in the direction of retrenchment or expansion, they are likely to favor similar action at the meeting of the next corporation whose fortunes they help to direct, and by and by things are going again or stopped again as the case may be.

A crucial test is now being made that will show whether business men really seek and use the kind of information that should guide them in the conduct of business. Under the direction of Secretary HOOVER the Department of Commerce has undertaken to publish in compact and simple form all the pertinent facts that can be gathered as to business trends and conditions. The reports have been issued for some time and are being improved and extended as opportunity affords. The reaction of the business world to these publications is now awaited. The plan is well conceived. The information is not complete, but it is so much more comprehensive than the information the individual has hitherto been able to get that it greatly increases his field of knowledge. What is the reaction in the chemical and related industries to the *Survey of Current Business?* We shall be glad to receive expressions of opinion either for personal information or for publication.

Use of Graphs In Plant Operation

SCIENTIFIC men and technologists are cognizant of the great value attached to the use of the graph in visualizing figures, since it is one of the basic studies in technical curricula. Relatively few of these men promoted to responsible charge of plants have thought to apply the graph to the everyday details of plant management and control.

Study of an article presented on another page under the heading "Graphic Record of Sulphuric-Acid Plant Operation" should open up a line of thought which may well lead to the education of superintendents and foremen in the use of the graph and its subsequent installation as part of the daily record.

Certainly the average individual engaged in running the process has a native intelligence enabling him to grasp the meaning and application of the ordinary chart.

Graph usage is simple and should be made a tool of the operator as well as the student.

Chemical Storage Of Power

THE discussion of Muscle Shoals as a power project and broad industrial chemical opportunity has developed a thought rather new to chemical engineers—namely, that the storage of power in peak flow periods should be done by chemical means. This idea certainly has interesting possibilities, and these should receive careful study on the basis of engineering facts, for if the opportunity really exists which some credit to this scheme, it will mean marvelous new things in many localities.

The Tennessee River at low water could produce relatively little power (estimated for Dam No. 2 at less than 50,000 hp.) as compared with the maximum at flood periods which would supply well up into the millions of horsepower if all the water power could be utilized. Obviously investment for the period of maximum water flow is altogether out of the question. Also a minimum power development of 50,000 hp. would be inefficiently low. Therefore by storage of water it is possible to insure substantially 100,000 hp. continuously through 12 months, considering the Wilson dam alone. By storage in suitable impounding reservoirs on the upper river or by installation of other power dams above the No. 2 or Wilson dam, the flow would be still further regulated and a continuous horsepower correspondingly higher would be available.

At Dam No. 2 it is proposed that the installed horsepower be 600,000. Probably 250,000 hp. can be made continuously available at this point by supplementing the power from the dam during periods of low water with steam power from the plants connected with Nitrate Plant No. 2. However, it is reported that Mr. FORD intends still further to supplement power for continuous processing throughout the year by a third means, which might well be called the "chemical" storage of power.

One proposal is that during periods of high water some of the electrical energy be used for making metallic sodium. This metallic sodium would then be put in storage under oil to be used as a reagent during periods of low water flow. As such reagent, it would enable an operator to carry out processes of high energy demand such as the manufacture of aluminum, magnesium or other similar light metals from their oxides. Thus a chemical process would be substituted at low water periods for an electrochemical method which doubtless would prevail during periods of maximum power.

At first thought it does not appear that the investment necessary for this manufacture and storage of sodium would be as economical as corresponding investment in storage dams on the upper river, which would permit uniform delivery of power from the Wilson dam because of uniform flow of water. However, it would be imprudent to draw any such conclusion without a very careful electrical and chemical study of the problem from an engineering point of view. Things quite as novel as the use of sodium for a reagent have been made successful in times past and if this proposal proves to have substantial foundation in engineering fact, it will contribute much to the success not only of Muscle Shoals but also of other developments where irregular runoff results in large seasonal fluctuation in power.

Green Fields and Pastures New

DR. LOUIS BERMAN, who is an associate in biological chemistry at Columbia University, has written a book on the "Glands Regulating Personality," which some day we may review at length. In the meantime it points to the gate of one of the most fascinating but involved and as yet untilled fields of organic chemistry. By merely glancing in, however, we find almost irresistible invitations for research.

These ductless glands in every one of us are substantially the same—but only substantially so. They differ in particular, just as our fingerprints differ. And so their products, which are substantially the same, differ in mass and in mixture. These products are carried in the blood and delivered where they are needed. The secretions are called hormones, which indicates that they arouse or set in motion; and it has been said of them that they are "chemical messengers, sent from one organ to another through the public highway, which is the blood." Again, the stream of blood has been likened to a moving platform on which the various hormones embark and from which they alight where the signal or a field of force attracts them, or where a barrier opposes their further progress.

Still greatly to be studied are the functions of the hormones or secretions from ductless glands. The glands are located all over the body—in the head, in the throat, in the chest, on the kidneys and in the abdomen. Some stimulus excites a gland to activity and soon its secretion is at work, arousing curiosity or fear or anger or affection. These emotions are chemical!

If study goes far enough in this subject, it may throw great light on the treatment of insanity, for it stands to reason that with many sufferers it is the excess of some particular emotion, due to a gland working only a little out of its proper proportion, that causes all the trouble. Only lately at Sing Sing prison an operation was performed along these lines on a habitual criminal, by transplanting glandular tissue from an executed man into him. He shows signs of becoming normal under the better balance of hormones, but of course some cheerful idiot whose glandular secretions have mixed themselves up into soup claimed to have discovered that a law forbids any such "interference" with what is blasphemously called "the work of GOD."

When blood analysis shows what hormones are lacking and what are in excess, and when enzymes are so understood that we shall know the stimulus for each ductless gland, there may be far less misery in the world.

Trade Association Activities and the Industrial Press

To the Editor of Chemical & Metallurgical Engineering

SIR:—As you pointed out in an editorial a few weeks ago, the activities of trade associations are now limited as a result of the decision of the United States Supreme Court in the case of the American Hardwood Manufacturers' Association. It appears that the maintenance of open-price information must be discontinued unless such information can be supplied by some means other than through the confidential reports of the trade association secretaries.

Doesn't this condition offer an unusual opportunity for co-operation between the trade associations and the industrial press? The industrial journals now carry, in addition to the purely technical information, price lists, condensed financial statements of the leading companies, discussions of employment problems, etc. Is it not a logical step forward for them to print production figures, sales statistics, average costs and other data now collected by the secretaries of the various trade associations? Let the trade association secretary be given a page or two for the presentation of his statistics in one or more of the leading industrial or technical journals serving his particular industry. The secretary should have no connection with the editorial staff of the journal. He should present his data without comment or discussion and his contributions should be printed as so much current industrial news. The editors of the magazine, however, would have a perfect right to comment on the data presented and to interpret them for the good of the industry.

In the Hardwood Manufacturers decision the Supreme Court commented on the association's "plan" of daily, weekly and monthly reports as follows:

> It is futile to argue that the purpose of the "plan" was simply to furnish those engaged in this industry the equivalent of such information as is contained in the newspapers and government publications with respect to the market for commodities sold on boards of trade or stock exchanges. One distinguishing and sufficient difference is that the published reports go to both seller and buyer, but these reports go to the seller only; and another is that there is no skilled interpreter of the published reports, such as we have in this case, to insistently recommend harmony of action likely to prove profitable in proportion as it is unitedly pursued.

The presentation of these trade statistics in an industrial journal would make them available to both buyer and seller, and therefore no legal complications should be produced. In this connection Gilbert H. Montague of the New York bar has made the following illuminating statement:[1]

> It is clear that comment and advice based upon trade statistics is dangerous when indulged in by the trade associations themselves, yet the same advice and comment may be quite harmless when given independently by a publication that is not a member of the association and which is accessible to buyer and seller alike. The editor of a trade publication can usually make such comment as he pleases for the benefit of the industry as a whole, and a discussion of demand and production which would bring down the whole force of the Department of Justice if emanating from a trade association secretary might be wholly innocent if published independently in the editorial columns of a trade or technical publication.

The average progressive manufacturer has come to see the advantages of the trade association and he appreciates the benefits of membership in it. He does, however, guard very carefully what he considers the vital statistics of his particular business. He probably would hesitate to send in his sales figures, costs, etc., to the assistant editor of an industrial magazine. He might also be opposed to sending such data to some unknown clerk in the Department of Commerce or to any other government agency. But the secretary of the trade association is in a different position. The manufacturer has a voice in appointing him and he pays a part of his salary. He has confidence in him. He knows that the data concerning his own business will go only to the secretary, and that they will be averaged or totaled with the corresponding data of his competitors. It seems likely, therefore, that the publication of these statistics under the conditions outlined above would receive the support of the manufacturers. Why doesn't the Synthetic Organic Chemical Manufacturers' Association try it?

The Manhood of Humanity

To the Editor of Chemical & Metallurgical Engineering

SIR:—In your issue of Jan. 4 is a long review by Ellwood Hendrick of Count Korzybski's "The Manhood of Humanity; the Science and Art of Human Engineering." Mr. Hendrick spoke favorably of the book and seemed impressed by its arguments. Having a respect for Mr. Hendrick's opinions, I was surprised that he took the book so seriously, just as I had been surprised that Prof. Keyser of Columbia University recently devoted a laudatory address to it. When I tried to read the book and comprehend the valuable theories it was said to contain, I concluded either that the book had been grossly overpraised or that I am especially dense at understanding such things. Today I noticed an unfavorable review of the book by Robert H. Lowie in *The New Republic* of Feb. 8, and it seems to me that his condemnations are justified. He points out that the so-called epoch-making discovery of man as a "time-binder" is not new at all; that the mathematical basis of the theory is inconsequential; and that the naïve assumption that human nature will reform itself when thus shown the mathematical error of its ways is laughable. With all respect to Mr. Hendrick, Prof. Keyser and the others who have praised the book, I agree with Mr. Lowie that Count Korzybski's solution of "human engineering" is not worth reading or thinking about.

Some New Petroleum Products

In the article, "Some New Petroleum Products," by J. H. James, published in our issue of Feb. 1, 1922, the lines at the top of page 212 should read "Rate of water feed to vaporizer, 0.6 liter per hour" instead of "6 liters per hour" as erroneously printed.

When Does an Employment Contract Terminate?

To the Editor of Chemical & Metallurgical Engineering

SIR:—There is an element of truth in the editorial, "When Does an Employment Contract Terminate?" which you have sent to me for my comment. The difficulty exists more in a system that permits the wrongs as suggested, and more with greedy and unscrupulous officials of corporations and others, than with laws failing to protect professional men. As is suggested, court precedents may be needed more fully to safeguard their interests, since the law is a growing thing capable of being adapted to new conditions. Perhaps with the development of our modern industrialism with its innumerable ramifications and requirements for its own existence, as where it depends on secret processes, conditions surrounding employment contracts may demand court rulings, at least as to what would be presumed to be against public policy in such contracts. But here immediately we get into deep water.

One may imagine a case where a professional chemist is engaged in a factory founded on a secret process and bound by contract to keep the secret. He may give up the pursuit of all other lines so long that his usefulness in any other field or factory is permanently impaired. Yet he may be let out of his employment and by his agreement be restrained from engaging in the work he best knows or from imparting the information gained in the specialized line. Can we justly say that this is the fault of law or of our system, and if the fault of either, may it be corrected by statute or court decisions?

The right to contract for one's services is part of that pursuit of life, liberty and happiness proclaimed in the Declaration of Independence and guaranteed by the Constitution. To restrict the right to contract fully encroaches on this right, which inures to the benefit of both parties to the agreement. The right to break a contract is also a fundamental right. Nor may a court require one to perform a contract where it is for personal services, but a court of equity may restrain one from rendering like services to others under certain limitations.

In leaving open the right to contract freely, equity will protect the parties against fraud, coercion and undue influence as far as that is possible and where proper will relieve against such wrongs. If through stress of circumstances and conditions a person is unduly influenced to enter into a contract of service to his damage, equity will relieve him.

Peonage is involuntary servitude and is not permitted under o .r laws. One may contract to render service in payment of an obligation, but he may leave his employment at any time he chooses. No law or court may force him to render the service agreed upon. By contract one may be restricted in his field of operation or work, but it is against public policy for one to agree wholly to refrain from following a vocation, going into business, etc. One may not bargain away his right to earn his living. In theory at least he may not bargain away his ability or diminish his ability to earn a living. Such would be against public policy, and any contract based thereon would be unenforceable. Should an employer know that his employee was in necessitous circumstances influencing his entering into a contract, and such employer took advantage of these facts to the detriment of the employee, equity would relieve the employee and discharge the contract. Obviously charging the employer with such knowledge is difficult to prove, since the employee studiously endeavors to hide his necessitous condition. We regard it good business as well as perfectly permissible for an employer to attempt to keep secret his secret processes, to keep specialized knowledge and discoveries from his competitors, and therefore to put provisions in the employment contract requiring the employee not to disclose information or not to engage with competitors, and the like. It is doubtful if such contracts can be enforced, at least in such a manner as to protect the employer as he intends.

If large technical corporations extort, as the price of employment, contracts from their employees forever limiting a man's usefulness outside their own factory walls, the writer is of opinion that such contracts are unenforceable and valueless to the employer except to "scare" the employee. Of course, the corporation with its money has the advantage in being able to litigate, and such might in many instances result in a denial of justice to one unable to litigate. Because of this denial of justice a federal investigation might be a worthy thing, as suggested, though a relieving statute might not and probably would not be deemed advisable.

No contract is binding on the injured party where coercion enters in. But the coercion must come from the other party to the contract. Coercion is the result of fear of some harm from threatened force. Undue influence is the more proper term to be employed in the sense as discussed here. Even undue influence must be used, or advantage taken of one's condition, by the employer party to the contract.

Recent Progress in Electrical Precipitation

To the Editor of Chemical & Metallurgical Engineering

SIR:—I am surprised as well as embarrassed that you have thrust honor upon me for having developed the mathematical equation given in the article by Evald Anderson on "Recent Progress in Electrical Precipitation," CHEMICAL & METALLURGICAL ENGINEERING, Jan. 25, 1922, p. 152. The truth is that I had nothing to do with the development of this equation, which we feel represents a distinct advance in the art, it having been done by A. A. Schmidt, who is in charge of our engineering work.

WALTER A. SCHMIDT.

Los Angeles, Cal.

On the Theory of Hardening of Metals

Prof. Honda has called attention to unfortunate errors in his paper published in CHEMICAL & METALLURGICAL ENGINEERING for Nov. 30, 1921 (vol. 25, p. 1003). Conclusions noted under the caption "Results of Investigation of Duralumin" should read:

2. The above effect of quenching is due to the dissolution of copper and magnesium compounds in the aluminum, the process of solution or separation being very slow. Thus duralumin is in a somewhat hardened state even if it is cooled very slowly from 500 deg. C.; a perfect annealing is obtained only by heating the alloy at 350 deg. C. for 1 hour or more.

3. Up to about 6 per cent Cu, alloys of Al and Cu show by quenching an immediate hardening, but very little effect on aging. Hence the immediate hardness is partly due to the dissolution of $CuAl_2$ in Al.

5. The aging after quenching is attributed to the dissolution of Mg_2Si in the $CuAl_2$ solid solution in Al. It is not due to metallic magnesium, because a mere increase of Mg does not result in an increase of aging effect, but an increase of both Mg and Si in the proportion of the compound Mg_2Si magnifies the same effect.

The Chemical Industry of Russia

By V. Leitis

PRIOR to the war, the chemical industry of Russia, and even her chemical trade as well, were in German hands. Every important German chemical concern had its branch in Russia, where—aided by the Russian protective tariff—it prepared fertilizers and all possible drugs and medicines, except the patented ones, which were made in Germany to keep the formulas secret.

German Influence

The Russian educational institutions were not able to develop chemists in sufficient numbers, and many came from Germany. As a result, almost every chemical plant—even the purely Russian ones—and every laboratory in Russia had German chemists. On the other hand, to keep Russians away from German secrets, those Russians who graduated from German chemical schools were not accepted as employees in Germany. The Aktien Gesellschaft für Anilinfabrikation, Badische Anilin- und Soda-fabrik, Farbenfabriken vorm. Friedr. Bayer & Co. were among the leading chemical firms in Russia. In regard to their size, it may be mentioned that in 1913 the Bayer company alone employed about 330 chemists and 280 engineers and mechanics. Under such competition, Russia was not able to develop its own chemical industry. As a result, Russia not only used chemical products made in Russia by Germans, but also imported heavily from Germany. Thus, in 1914 Russia imported from Germany the following quantities of fertilizer materials:

	Tons		Tons
Superphosphates	300,000	Chilean nitrate of soda	48,000
Thomas slag	177,000	Kainite, guano, etc	32,000
Total			557,000

It should be remembered that Russia is rather rich in phosphates which could be converted into superphosphates. Some Russian factories were engaged in this line, producing about 100,000 tons of superphosphates annually, but they were handicapped by German competition and better German selling methods. Furthermore, they did not enjoy as easy bank credit as the Germans, owing to the great German influence in Russian commercial banks.

The production of soda was entirely in Russian hands (Loobimoff & Co.), likewise a great part of the sulphuric acid industry, although some works located in Riga (present Latvia) which used imported ore were owned by Germans.

Development During Early Part of War

The war stopped the activities of Germans in Russia, the imports ceased, and of necessity Russia was compelled to create a chemical industry of her own. Russian chemists were invited and gradually the industry grew stronger until 1918, when Bolshevists came into power, and by nationalization and other communistic means checked the growth of this young industry.

At the end of 1919, there were in Russia the following chemical works:

	No.		No.
Salt and acid	35	Potash	45
Soda	3	Quicksilver	1
Dyes	3	Mineral wax	1
Compressed gas	14	Phosphates	9
Prussiate	2		
Total			113

All these plants were of small size, their equipment being antiquated, worn out and broken to such a degree that the Bolshevists could put into operation only eighteen of them, employing 7,225 workmen.

The output of these plants in 1920 to 1921 was extremely low when compared with pre-war figures, as shown in Table I.

TABLE I—PRODUCTION OF CHEMICALS IN RUSSIA

Products	1920, Tons	1921, 6 Months, Tons	1913, Tons
Sulphuric acid	13,827	1,287	200,000
Oleum	4,845	..	10,970
Nitric acid	430	66	24,355
Hydrochloric acid	15,843	33	65,483
Copper sulphate	91	114	No figures at hand
Superphosphates	5,833	..	100,000
Bichromate of ammonia	58	22	No figures at hand
Salts:			
Sulphate	14,013	..	.....
Chlorate	292	..	.....
Carbonate	11,050	..	.....
Chromates	1,110	..	.....
Sodium sulphite	807	..	.....
Bleaching powder	3,000	..	.....
Other salts products	850	..	.....
Total	72,049	1,522	

Effects of Bolshevist Rule

The present inefficiency of the Russian chemical industry can be explained by the communistic régime: crippled transportation, inefficient management, underfed and underpaid workers, lack of fuel and raw material. To be progressive, this industry needs the coperation of scientists, and if we examine the conditions in Russia we shall find everything there in favor of the uneducated man, with nothing for the intellectual class. The "intelligentia" has been pursued and despised by the Bolshevists and rule of the uneducated class has been established. The intellectual class was driven to compulsory physical work, street cleaning, wood cutting, even work in coal mines, but the scientific work could not be made compulsory. It was a highly mistaken idea to imagine that the proletariat alone would be able to manage the business of the state, putting the intellectual class aside. Since 1919, the Bolshevists have tried to remedy this fault by granting some privileges to the scientific and intellectual professions, but unfortunately too late—the country has already been ruined.

The harm done to agriculture is readily appreciated if we consider the total production and import of fertilizers in pre-war times (over 700,000 tons) and compare this figure with the 5,833 tons produced in 1920 (there was no import of fertilizers because of lack of money). In 1921 no fertilizers were produced.

For the production of dyes, 325 workers were employed, and the output, according to Bolshevist reports, was sufficient to supply only the needs of the state printery, where the Bolshevist paper money was printed.

The same condition affected the production of drugs and pharmaceuticals. In 1919-20, the thirty-two existing drug factories employed only 1,551 operators, the output being as follows:

	1913, Kg.	1919, Kg.	1920, Kg.
Chemical preparations	2,000,000	75,117	71,576
Drugs	3,000,000	283,264	401,176
Disinfectants	1,000,000	.....	226,529
Total	6,000,000	368,381	699,281

Regarding the future of the Russian chemical industry, foreign influence will undoubtedly prevail. If anything is being produced at the present time, it is done so regardless of cost, since payment is made with the worthless Bolshevist paper money under the management of the state. Such a situation cannot last indefinitely.

Riga, Latvia.

Grain Growth and Recrystallization in Metals. I—Definitions

Technical Definition of Recrystallization, and a List of Recrystallization Temperatures for Common Metals—Various Methods for Measuring Grain Size, Shape and Volume—Elongated Grains May Not Always Contain Strained Metal, Even When Apparently Stable

By ZAY JEFFRIES and R. S. ARCHER
Research Bureau, Aluminum Co. of America

CRYSTALLINE structure of metals was discussed in a previous article.[1] The present articles will deal more specifically with the sizes and shapes of grains produced on the solidification of metals, on grain growth in the solid state and on recrystallization.

When a metal freezes the sizes and shapes of the crystalline units or grains vary in accordance with the conditions obtaining at the time of crystallization. In general there is no distinction made between crystallization and solidification, since the latter is due to the former. As a rule rapid solidification produces smaller grains than slow solidification. The grain size of cast metals, provided they have not been plastically deformed, cannot be changed by heating below the melting point. This is true no matter what the grain size in the cast metal.[2] When a cast metal is plastically deformed at a temperature high enough so that no "strain hardening" results, microscopic examination shows that new and usually smaller grains have been produced. Working a metal at such temperatures is termed "hot-working." Plastic deformation has thus caused the grains to undergo some change which usually produces several grains from each of the original ones. Supposing the metal under consideration is copper and assuming that the temperature of working is 600 deg. C., severe working will produce a marked "refining" of the structure—that is, the grains will have increased greatly in number and will have decreased proportionately in size. If the metal is now heated to say 800 deg. C., it will be observed that grain growth has taken place and that there are fewer and larger grains. The melting point of copper is 1,084 deg. C.; this grain growth occurs therefore while the metal is in the solid state. In what is termed "normal grain growth" the higher the temperature and the longer the time at heat the larger will be the grain size. In some cases grain growth is very rapid at a given temperature for a short time, after which longer exposure seems to produce no further change. This is a condition of metastable equilibrium. An increase of temperature usually produces further grain growth in these cases.

Definition of Recrystallization

When a metal is plastically deformed at a temperature so low that "strain hardening" results, it is said to be "cold-worked." Microscopic examination shows that the grains have been deformed in about the same manner and magnitude as was the piece of metal taken as a whole. Except in the soft metals like lead, tin and zinc, these distorted grains do not change at room temperature. On heating, however, a temperature is reached, different for different metals and for various degrees of cold work, at which the distorted grain structure is replaced by new grains usually approximating an equiaxed shape. By "equiaxed grain" is meant one whose diameter is approximately the same in all directions. Hardness tests show that most of the "strain-hardening" effect is lost with this change in structure. This change is usually referred to as "recrystallization," and the lowest temperature at which new grains visible under the microscope appear may be called the "recrystallization temperature." Recrystallization temperatures for certain metals after severe cold plastic deformation are given in Table I.

TABLE I.—RECRYSTALLIZATION TEMPERATURES

Metal	Approximate Lowest Recrystallization Temperature Deg. C.	Metal	Approximate Lowest Recrystallization Temperature Deg. C.
Iron	450	Magnesium	150
Nickel	600	Tantalum	1,000
Gold	200	Tungsten	1,200
Silver	200	Molybdenum	900
Copper	200	Zinc	Room temp.
Aluminum	150	Lead	Below room temp.
Platinum	450	Tin	Below room temp.
		Cadmium	About room temp.

We intend to present a definite conception of the mechanism of recrystallization which will define "recrystallization" in a fundamental manner. The values given in the table must be considered as approximations and are selected with reference to the lowest temperatures after severe cold work, which will produce new grains *visible under a high-powered microscope.* The recrystallization temperature is lower the greater the amount of cold work, the lower the temperature of working, the purer the metal, the smaller the grains before deformation and the longer the time of exposure at temperature. It is only a matter of usage that the temperature of the beginning of recrystallization should be selected with reference to the appearance of grains which can be seen with a microscope; other measurements such as tensile strength, electric conductivity or hardness give more sensitive indications of the first changes of structure. It is true, however, that when new grains can be seen, the change toward the properties of the annealed metal is marked. Technically, "recrystallization" is the structural change produced in a cold-worked metal on changing from the strain-hardened state to the annealed state. Although there are an infinite number of stages, curves relating certain physical properties to temperatures of heating a cold-worked metal will often show sharp changes within a small temperature range and a gradual change both above and below this

[1] "The Crystalline Structure of Metals," Jeffries and Archer, CHEM. & MET. ENG., May 4, 1921, pp. 771-779.

[2] Iron is an exception to this general rule in that it undergoes an allotropic change at 900 deg. C. accompanied by a complete change in crystal structure with the formation of new grains. Grain growth also takes place in some cast alloys as a result of phase changes.

range. Such curves are given in Fig. 1, showing the tensile strength, elongation and electrical conductivity changes in cold-worked copper heated at various temperatures. A sharp break in all of the curves corresponds to a structural change, the elongated (strain-hardened) grains having been replaced by small equiaxed grains. The sharpness of the changes in Fig. 1 shows the justification for a term such as "recrystallization" to designate the temperature range within which they occur.

If a strain-hardened metal is heated to a temperature just below that of recrystallization, no visible grain growth takes place. On heating to any higher temperature, grain growth takes place, the higher temperatures and extended exposures producing the larger grains.

When metal powders are briquetted and heated to temperatures somewhat below their melting points, grain growth takes place. In the case of tungsten, or molybdenum or nickel powder, the density of the briquet may be only 60 per cent of that of the "solid" metal, but after heating to a high temperature but below the melting point, the density becomes about the same as in the cast or worked metals. On heating these briquets, the grain size normally[3] increases both with the temperature and with time of exposure.

Electrodeposited metals are crystalline. The grain size may be large or small, but heating such a metal may cause grain growth below the melting point.

Iron is unique in its grain growth characteristics because of the allotropic change in a temperature region permitting grain growth. If iron is cast, it first forms grains of gamma iron crystallizing with a face-centered cubic lattice. On cooling, gamma iron changes completely into a body-centered lattice at about 900 deg. C., and this transformation gives rise to entirely new grains. If the iron is kept below 900 deg. C., it behaves much like any other metal within a similar temperature range. It can be cold-worked and hot-worked and the grain growth characteristics can be studied at temperatures up to 900 deg. C. On heating above about 900 deg. C., however, the structure again changes completely into new grains of gamma iron. Every time iron is caused to change from one crystal lattice to the other a new set of grains is produced. Pure gamma iron cannot be "cold-worked," because at the lowest temperatures at which it is stable it cannot be "strain-hardened."

Average Grain Size

Before proceeding with a more detailed account of grain growth phenomena, it will be well to explain what is meant by some of the terms used.

Grains are three-dimensional bodies roughly polyhedral in shape. Our observation of them, especially for the purpose of determining grain size, is usually on a polished plane section. The quantity actually measured is therefore not the volume of the grain, but some linear dimension or area. Furthermore, the grains in a given piece of metal of even the most uniform structure always vary rather widely in size. Rosenhain has pointed out that for practical purposes it is perhaps the size of the largest grains which is of most importance, and some specifications have been written upon this basis, rejecting material which contains grains exceeding a certain stated diameter or area. It is of course probable that the observed plane section of any particular grain does not represent its *maximum* cross-sectional area, but it is also probable that the maximum grain area observed on a polished section containing a large number of grains *does* represent fairly closely the maximum size of the grains.

It is more common to measure the *average* grain size over the observed area. The various methods of doing this will not be discussed, but a preferred method (which has been described fully by one of the authors in this journal[4]) will be outlined for purposes of illustration. The specimen is photographed at a known magnification, or if a photograph is not desired, the image on the ground glass of the camera may be used. A circle is drawn on the ground glass or on the micrograph representing a certain area on the surface of the specimen, selected so as to include a fairly large number of grains, preferably over fifty. A count is then made of the number of grains totally inclosed and also of the number intersected by the circumference of the circle. Twinned portions of grains are not counted as separate grains. The sum of the number totally inclosed plus half the number intersected gives the equivalent number of whole grains within the area of the circle from which the average number of grains per unit area or the average area per grain may be readily calculated. It should be emphasized again that this quantity does not represent the maximum cross-sectional area of the average grain but the average cross-sectional area such as would be cut by a plane taken at random.

A value which we will call the average grain diameter is obtained by taking the square root of the average grain area. This diameter has no exact physical meaning. It represents what would be the length of side of

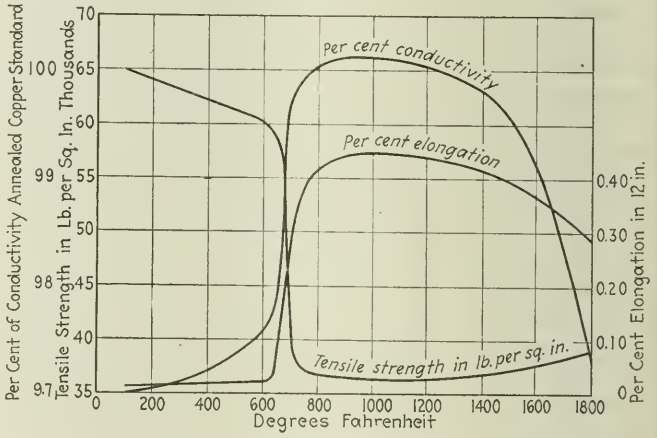

FIG. 1—VARIATION OF PHYSICAL PROPERTIES OF COPPER WIRE WITH VARIATIONS IN ANNEALING TEMPERATURE. (Bardwell, *Trans.*, A.I.M.E., vol. 49, p. 758)

the grains if they were all square. Actually the average grain diameter, determined in this manner, is sufficiently close for all practical purposes to the average intercept cut by a straight line through a large number of grains.[5]

When it is desired to make computations on the basis of volume, the hypothetical square grain may be extended to a cubical grain. The average grain volume is then equal to the cube of the average grain diameter.

It will be seen from the above that grain size meas-

[3] Deviations from this rule will be considered later.

[4] "Grain Size Measurements in Metals," Jeffries, Met. & Chem. Eng., 1918, vol. 18, p. 185.

[5] It is perhaps most scientific to express grain size in terms of the number of grains per unit area, since this is the quantity directly measured. The authors prefer, however, for general purposes to express grain size in terms of the average grain diameter in inches, with the object of giving as concrete a conception as possible of the actual magnitudes involved.

urements are only approximate. Some have objected to this inaccuracy and attempted by mathematical analysis to arrive at more exact expressions. The objection and attempt are unjustified in view of the real significance of the figures. The properties of metals are not affected to any marked extent by a variation in grain size of 25 per cent or even 100 per cent. Indeed such variations commonly occur from point to point in a supposedly uniform metal. The methods in common use for measuring and expressing grain size are therefore amply exact for the purpose.

Grain growth may occur without affecting the grain size as expressed by average grain area or diameter. During the first stages of growth the total number of grains within a given area does not change and hence the average grain size remains constant. It is not until some of the grains are completely absorbed that the measured grain size indicates the change. Some other means must be used for detecting *slight* grain growth. For most practical purposes, however, we are concerned with grain growth of such magnitude that it is well shown by changes in the measured average grain size.

Elongated Grains

When the grains depart widely and consistently from an equiaxial shape, as in cold-worked metal, it is often better to determine grain size by the intercept method—that is, by counting the grains intersected by a given length of straight line. It will be understood that the grains of a cold-worked metal are broken up into fragments which are in many respects equivalent to individual grains, but that we are here referring to the counting of the original grains. The average grain diameter may be determined in this way both in the direction of working and at right angles to this direction. A complete description of the grains requires measurements in three directions, corresponding to co-ordinate axes, and made on two surfaces usually at right angles to each other. The ratios of the average grain diameters thus determined indicates the shape of the grains and the amount of deformation that the metal has undergone.

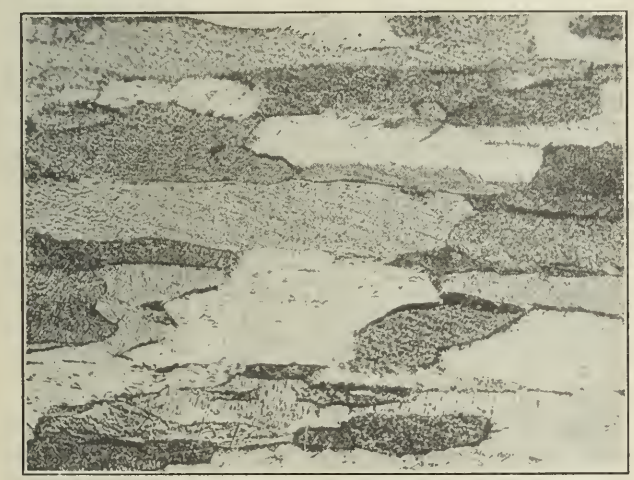

FIG. 2—UNSTRAINED GRAINS SIMULATING COLD-WORKED METAL IN DRAWN TUNGSTEN WIRE 0.020 IN. DIAMETER. × 250 (SYKES)

The term "worked metal" will be used in this article to denote metal which has been subjected to mechanical working of any kind, hot or cold, by rolling, forging, pressing, swaging, drawing or otherwise.

The word "strain" is used very commonly in connection with grain growth in a sense not altogether obvious. From the physical or mathematical viewpoint any deformation is a strain, including the elastic deformation represented by the first portion of a "stress-strain" diagram. But an elastic deformation does not constitute a strain, according to usage in connection with grain growth. Strain is sometimes used to denote stress, and at least carries an implication of this meaning. "Strain" as used in these pages does not necessarily involve stress. We may define a *strained metal* or grain as one which has been permanently deformed in such manner as to harden it. A hot-worked metal is not strained. The strain of a cold-worked metal is removed by annealing.

The hardness produced by work is called strain hardness or work hardness.

Unstrained grains are normally equiaxed in shape, but exceptions are very common. When a metal containing material which mechanically obstructs grain growth is subjected to considerable working, either hot or cold, it is often found to exhibit grains which are consistently elongated in the direction of the working, even after thorough annealing. An example of this type of structure in tungsten is shown in Fig. 2. These grains are unstrained, though not equiaxed. A distorted grain shape suggestive of cold-working is not therefore to be regarded as proof of strain.

When a metal solidifies in a chill mold it is often found that long grains grow out at right angles to the walls of the mold. These grains are referred to as "columnar," and they are of course unstrained. If the mold is circular or nearly so in cross-section, the grains converge toward the center, and may then be referred to as "radial grains."

(Part II, on Experimental Data and General Laws, will be published in a subsequent issue.)

Use of Rubber in Paper Manufacture Proves Advantageous

Experiments on the quality of paper in the manufacture of which small amounts of rubber latex are added to the fiber seem to demonstrate that the product is superior to the same material made without rubber. Vice-Consul Wade Blackard of Singapore reports the results of tests in the Feb. 13 issue of *Commerce Reports*.

It is claimed for the process that it will not only reduce the cost of paper manufacturing materially and simplify paper-making methods, but that it will greatly improve the quality of the product.

Experiments were made to show that with an ordinary fiber made into a paper containing one-tenth of 1 per cent of rubber the product had a folding number of 5,000 to 6,000 and a tensile strength two or three times that of the same material made without rubber. But with a rubber content of about seventy-five one-hundredths of 1 per cent the folding number reached 14,500, while the same paper made in the usual manner had a folding number of 30.

Another fiber beaten for half the usual time made into a paper containing 1 per cent of rubber had a folding number of 72,500 and a tensile strength of 87 lb. for a strip 1 in. wide, equal to 6,600 lb. per sq.in., or about twice the strength of a well-vulcanized rubber compound, such as is used in tires, for example. The bursting strength was about 40 lb. for a thickness of one-tenth of a millimeter.

Pottery Manufacture in the East Liverpool District

Plant Operations in the Manufacture of Semi-Vitreous China at Plant No. 5 of the Homer Laughlin China Co.—Raw Materials—Producing the Slip—Magnetic Separation—Filtering—Forming—Making the Glaze—Burning—Important Economic Factors

By CHESTER H. JONES

EAST LIVERPOOL, Ohio, located on the north bank of the Ohio River and connected with Newell and Chester, W. Va., on the opposite side, by steel bridges, makes one community dependent on the pottery industry and is the center of the manufacture of tableware in the United States. It is comparable in this respect with Stoke-on-Trent, in England, a town long the center of production for English china. The location of pottery manufacture at East Liverpool is purely traditional, for no native clays are used in the whiteware plants.

In 1839 James Bennet, an English potter, found a good clay here for making yellow and Rockingham ware. The general manufacture of whiteware began in 1879 and was followed by the use of underglaze decoration. The development of semi-vitreous china came about 1890 with better clays, different mixes and harder firing. The present product is an outgrowth of the white-granite ware and is known variously as semi-vitreous china, semi-vitreous porcelain, semi-porcelain and porcelain granite.

The plants and workmen were available for white ware manufacture, and conversion from yellow ware required only a change of raw materials. These were brought together from many scattered points, causing this location to develop into the largest center for the industry. Whiteware is the type of tableware having a fairly porous body covered with a brilliant transparent glaze. It has the general body composition of 52 per cent clay, 34 per cent flint (ground quartz) and 14 per cent feldspar.

The clay content is kaolin and ball clay. The former, being non-plastic, burns white, the latter, being very plastic and tenacious, fires to a cream or buff color. Kaolin gives whiteness and ball clay plasticity and bonding strength. Flint reduces drying shrinkage and gives rigidity during firing. It further promotes the escape of steam and gases during the period preceding vitrification. Feldspar fluxes at the higher kiln temperatures to a glass which dissolves some of the quartz and clay, cementing it into one mass. The amount of feldspar used in white ware does not completely eliminate pore space, which is the principal distinction between white earthenware and porcelain.

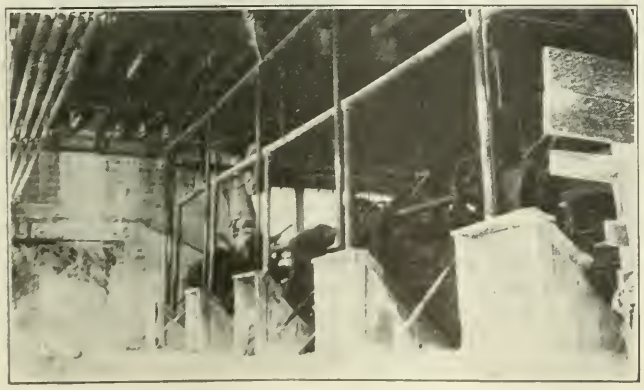

FIG. 1—VIEW ALONG TOP OF BLUNGERS

The chief producers in the district are Knowles, Taylor & Knowles, M. C. Nichol Pottery Co., Thompson Pottery Co., West End Pottery Co., Taylor, Smith & Taylor, A. M. Knowles, Vodrey and the Homer Laughlin China Co. Of these the last named is perhaps the best for description of the process.

The Homer Laughlin China Co. was started by Homer Laughlin, an English potter, in 1871. He erected and operated a two-kiln white ware plant and for many years was loath to expand for fear of sacrificing quality in quantity production. The company, with main offices in Newell, W. Va., now operates five plants, Nos. 4 and 5 being located in Newell and Nos. 1, 2 and 3 in East Liverpool. The total number of kilns in these five plants is seventy-eight. The yearly capacity is 2,000 glost kilns, or seven carloads, of china per day. This is approximately one-fifth of the amount of tableware manufactured in the United States. In 1920 the actual production of the five plants was 1,237 bisque kilns and 1,935 glost kilns, with an average natural gas consumption of 273,000 cu.ft. per bisque and 242,000 cu.ft. per glost kiln.

In 1914 Plant No. 5 was completed, and since it is the most recent of the group arranged for straight line flow of material from raw clay bins to packing and shipping department, a detailed account of the operations will be given in the following paragraphs.

Preparation of the Body

Constituents or raw materials used in making the body are all shipped into the district and include: English kaolin; English ball clay; Florida kaolin; North Carolina kaolin; feldspar; flint.

These are unloaded from railway boxcars to separate bins, whence they are drawn in required proportions to industrial car scales. This batch scale car is pushed by hand along the track directly to the rear of the battery of five blungers. Fig. 1 is a view along the top of the blungers. The car enters from the raw materials building through the double door on the left of the view and the batch is shoveled through the wooden charge openings appearing on the top of each blunger. Water is introduced through the pipes entering the top near each material charge opening.

The blunger tanks as well as the agitators or cisterns for holding slip are constructed from brick and concrete. The agitating mechanism consists of five single vertical shafts with paddles for each blunger connected by bevel gears to the continuous horizontal shaft running along the battery. Each gear on this shaft runs

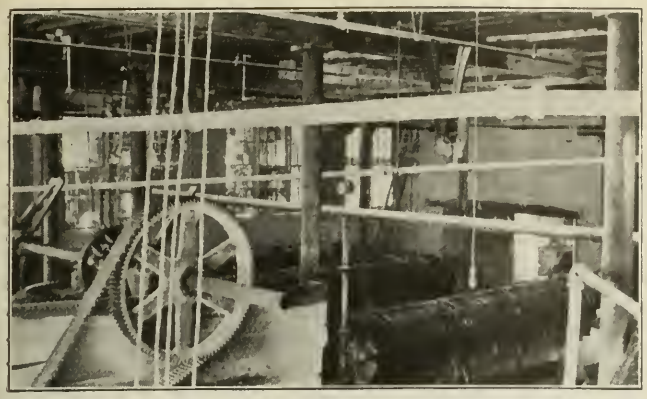

FIG. 2—FILTER PRESSES

as an idler until thrown in by separate clutch, thus permitting the individual operation of any blunger. Clutch operating handles are seen adjacent to the feed openings and convenient to the charging floor operators.

The main shaft is driven from electric motor by silent chain, as shown to the left in Fig. 2. This view also shows three of the five filter presses arranged on the main floor in front of and below the blungers with details of overhead water main leading to blungers and slip piping to the filter presses.

Treating the Slip

When the mixture of body materials and water has been whipped to the required consistency in the blunger to form a creamy slip, it is drawn from the bottom to a common header trough running along the front of the battery between blungers and filter presses and flows into an agitated cistern below the floor. Like all other storage tanks for clay slip, the liquid must be kept continually in motion by slowly revolving paddles mounted on a vertical shaft. Otherwise the solids would settle out of solution, rendering the pumping system immovable. The mechanism for driving the agitator below floor appears beneath the cage in the foreground of Fig. 3, and consists of bevel gearing with suspended agitator shaft driven by belt from overhead shaft.

From this agitator the slip is pumped by double-piston heavy-duty slip pump to the two large brick agitators above floor level, as shown in the background of Fig. 4. From each of these the flow continues to the revolving lawns in the foreground, where it passes through 12XX silk equal to a 150-mesh brass screen. Both lawns discharge directly into the Type U Dings Magnetic Separator, which is the low box appearing in the right front of the picture.

The slip enters the magnetic separator through pipes

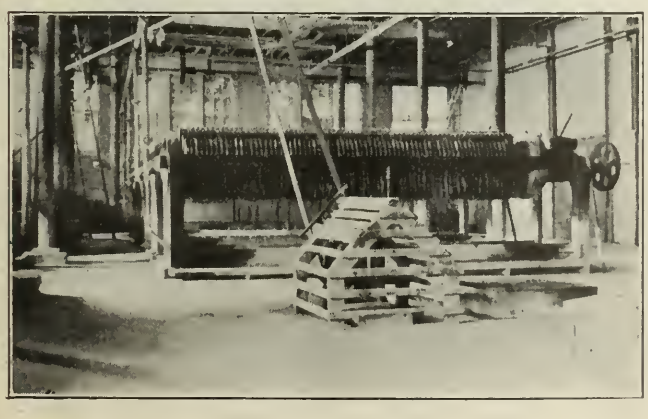

FIG. 3—ANOTHER VIEW OF PRESSES

in the rear end. The removable iron riffle bed is magnetized by 220-v. current from below, and as the liquid travels over the tortuous path all particles of solution are brought in contact, causing any native or abraded iron particles to adhere. At the discharge end of the separator the flow passes over a swinging cradle held stationary in place by an electromagnetic coil connected in series with the main magnetizing circuit and so arranged that should the power go off it will swing out of place by its own weight and cause the solution to fall in a launder for recirculation through the storage cisterns above. This insures that all clay passing through the separator will be cleaned of iron by the current.

Deposits of primary kaolins very low in iron opened up in the United States are so far quite rare. England is more fortunate in this respect, which accounts for the American potter's preference for the imported Eng-

FIG. 4—BRICK AGITATORS AND REVOLVING LAWNS. MAGNETIC SEPARATOR IN FOREGROUND.

lish clays. On the other hand, plastic ball clays of very good quality have been located in both Tennessee and Kentucky.

Filtering

The iron-free slip passes directly from the separator to a pair of agitators below floor level, whence it is pumped by Patterson heavy-duty pumps operating at 80-lb. pressure into the battery of five filter presses shown in Figs. 2 and 3. Cakes of plastic material are put through an English Boulton pug mill in the adjoining room. The filter cloths are thoroughly washed at frequent periods to prevent premature decay through bacterial action. This is done in a wooden box supporting a squirrel-cage rotor in which the cloths are revolved as the fresh water plays through the apparatus. Creosote is added as a preservative during this washing process.

From this point the pugged clay takes two courses through the plant. Part is used directly in the forming or jiggering department, the remainder goes to make up the colloidal solution or casting slip. Molds for use on the jiggers and for the casting process are produced

FIG. 5—SECTION OF JIGGER ROOM.

on the same floor as the preparation room just described. Large quantities of plaster of paris are consumed in a very complete mold production room.

Jiggering

Fig. 5 is a view of one small section of a large jigger room. The tables are arranged in one long row with the light from outside windows giving perfect illumination. Instead of placing the tables directly against the wall, as is commonly practiced, the space in front, as shown in the picture, permits the delivery of clay to the front of each bench by hand truck without interfering with the jigger operator.

The jigger shown in the foreground is for use in throwing a variety of the deeper pieces, a long up and down travel being obtained by motion of the collar on the column. To the left rear is an ordinary jigger for throwing plates, etc. As each piece is formed it is removed, together with the bottom mold, from the jigger and placed on the ferris-wheel driers seen directly back of the operators' benches.

Fig. 6 is a close-up view of the loading side of one of these driers. The outfit consists of a large room with board walls which is heated by steampipes. The revolving ferris-wheel arrangement of shelves filling this space is moved by the operator, who turns the crank communicating with the worm and gear attached to the main shaft as often as he desires to bring empty shelves in front of the opening for loading. Piece and mold are thus gradually passed over the top to the opposite side, where they are removed after remaining for 8 to 12 hours in the drying atmosphere. The molds are returned by hand to the shelves shown on the left, Fig. 6, where convenient for the jiggerman to use again.

FIG. 6—DRIER

After trimming off the rough edges from the dried pieces, they are transferred to the green ware room, where all ware is sorted and counted.

Casting Department

Casting slip is prepared near the pugging room on the first floor. Fig. 7 shows the apparatus used for this work, a machine made by Gosling & Gatensburg, Hanley, England, which has proved very satisfactory for the purpose. As will be noted, it consists of a cast-iron cistern placed with the top near the floor level, with a small blunger on the right set directly on top of the cover. The belt-driven cross-shaft above drives both the blunger shaft and agitator shaft through bevel gears. The batch of pugged clay, sodium silicate and sodium carbonate is put in the blunger through the top cover. These latter reagents operate to make a heavy but fluid suspension with reduced water content.[1] When thoroughly agitated the batch is drawn to the lower and larger agitator beneath, whence it is later pumped for use to tanks on the floor above. Two troughs or launders are seen emptying into the top of the agitator, Fig. 7. These convey waste material and slops from the casting floor to this cistern, thus making a considerable saving of otherwise wasted slip.

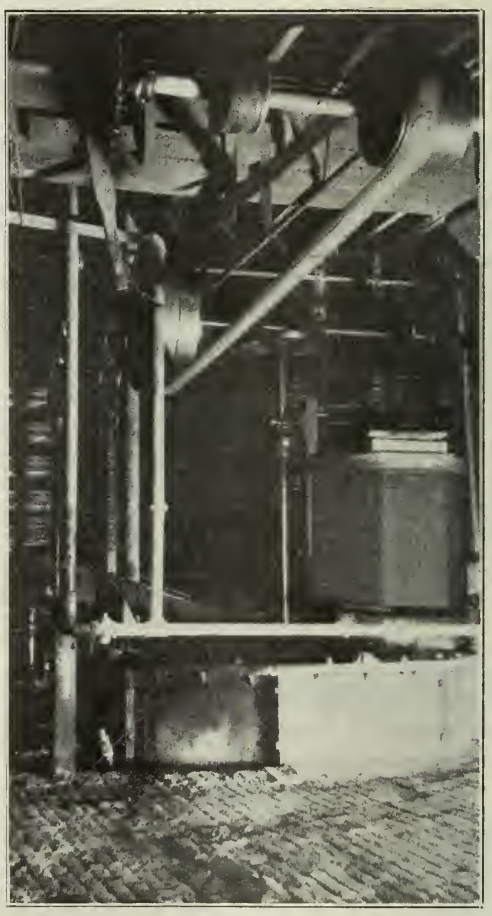

FIG. 7—APPARATUS FOR PREPARING CASTING SLIP

[1]See Bureau of Standards Technologic Paper 51 and University of Illinois Bulletin 17, both by A. V. Bleininger.

Fig. 8 is a view of a small section of the casting room. On the upper right hand appears one of the tanks which receives the slip from the apparatus described above, together with the piping system for serving material to the operators. In the foreground are typical plaster of paris molds used for casting all sorts of ware such as vegetable dishes, sugar bowls and even cups and large pitchers complete with handles. The casting of ware with handles is a distinct advance over the old operation in which cast handles are attached by hand after the main body of the piece has been thrown on the jigger.

Clay slip is drawn into the molds through the valve on the hose outlet, one of which appears lying on the molds in the foreground. After standing a few minutes, the excess slip is poured out, the mold is parted and the cast piece is trimmed and ready for transportation to the green room.

Making the Glaze

The glaze is prepared from frit or glassy constituent, boric acid, borax and other mill additions. The frit is prepared from the following typical formula:

	Lb.
Boric acid	100
Borax	50
China clay	25
Flint (natural)	180
Lime	8
Flint from sagger linings	80

This is placed in saggers in the kilns and melted to a glass. The company has recently erected a gas-fired reverberatory furnace to replace the practice of using

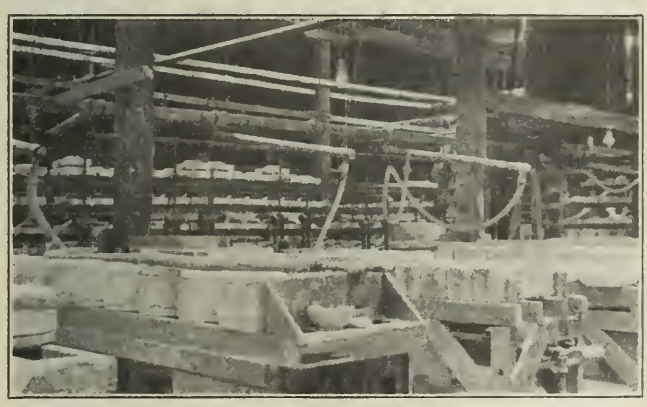

FIG. 8—SECTION OF CASTING ROOM

saggers. This glass or frit is removed to the glaze room, where it is ground in the chaser mill. During the grinding, china clay, flint, whiting, zinc oxide and feldspar are added, the whole being thoroughly mixed and ground in the dry state. The composition of this mixture must be such as to produce a glaze which will fit the bisque body according to the degree of burning of the body. It is a matter of obtaining proper coefficient of shrinkage of the glaze.

Fig. 9 is an interior of the glaze room. To the right is the track scale into which the mill additions are weighed and transported to the chaser mill, the latter not shown. The mixture from the chaser mill is carried to the four 1,200-lb. Patterson pebble mills on the left, where it is ground wet to a creamy consistency. These mills are emptied to boxes beneath. These, in turn, discharge to a common launder leading to the hexagonal rotary lawn appearing beneath the pebble mill in Fig. 10. This lawn is covered with No. 14 lawn silk. The lawn box empties to an agitator tank beneath the floor,

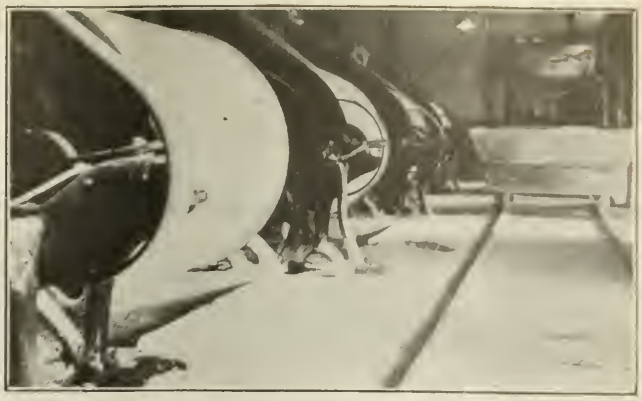

FIG. 9—GLAZE ROOM

whence the glaze is pumped by the small outfit, shown on the left of the view, to the dipping department.

The glaze tanks in the dipping room are all provided with agitators. Glaze is drawn off in ordinary galvanized washtubs, the ware which has received the bisque burn is dipped therein by hand and subsequently dried over steam pipes. It is then returned to the main kiln room, where both the glost and bisque burning is carried on. Ware from the green room here receives the bisque burn and is passed on as mentioned to the glaze room. The bisque is stamped with the trademark, plant and lot number just before dipping in the glaze.

Sagger Production

The sagger department is located in the basement. The mixture used consists of 50 per cent grog from broken saggers, with the balance a mixture of two clays. One is open firing and refractory, while the other clay is dense firing, though somewhat less refractory. Both are American clays.

Both hand molding and machine are employed in the forming. In the latter case a motor-driven Crossley sagger machine is used to develop about 1,000-lb. pressure per square inch. The sagger glaze mix consists of:

	Lb.
Whiting	30
Plaster	5
Feldspar	250
Flint	75
China clay	70
White lead	120
Red lead	20

Burning

Gas is burned at 45c. per 1,000 cu.ft. While this is expensive, there is a production saving of 15 per cent more ware as compared with coal firing. In the winter coal is used on the bisque kilns and some glost kilns and

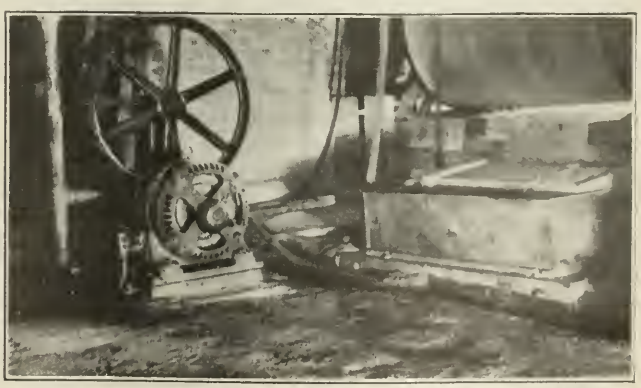

FIG. 10—HEXAGONAL ROTARY LAWN FOR GLAZE

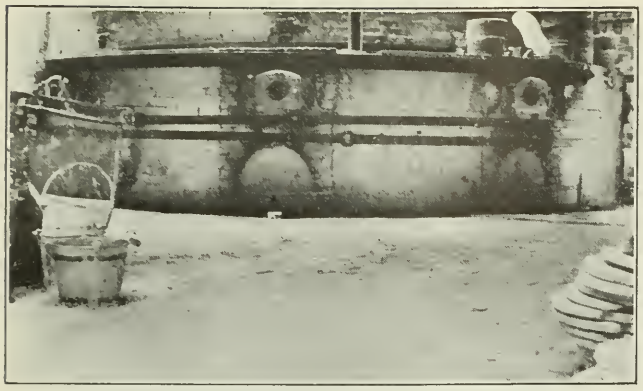

FIG. 11—UP-DRAFT PERIODIC KILN

for the purpose coal grates on wheels are inserted under fireboxes.

The main kiln room has seven bisque and nine glost kilns. They are 18 ft. in diameter, up-draft periodic type. Fig. 11 shows two of the fireboxes on a kiln with gas pipe feeding through the ash door opening. Cones and draw trials are used to determine and regulate ordinary firing conditions. Veritas disks are used when trouble occurs and occasionally Albany and body trials are employed. The bisque is burned to cone 8 and the glaze to cone 6.

Lowden overhead tram system is employed for handling saggers, coal and ware to and from kilns. A complete coal-handling system is installed. Standard gage railroad hopper cars dump to bin beneath track. Outlet permits coal to drop to pit at one side of track. An electrically driven hoist with grab bucket takes coal from this pit and deposits it either on the storage pile beneath overhead trestle or to overhead bin, whence it is transported to the kiln room.

Decorating Department

There are three general methods of decorating the ware after the glaze is burned on. Line decoration involves the spinning of the piece on a small horizontal wheel while the brush is held against the surface. Stamp decorating employs a rubber stamp with pad and is confined principally to the application of gold designs. Decalcomania is a transfer paper with the design printed thereon from lithograph stones. The inks are mineral colors. The design adheres to the varnish, previously applied on the proper portion of the ware, when the paper is washed away. All these operations are carried on by hand. The production of decalcomania paper has been improved by double and triple printing on lithograph presses which piles up the ink, giving a relief effect when burned onto the ware. Each pottery purchases exclusive designs by the sheet from the decalcomania manufacturer. About fifty open patterns are kept in stock. The artistic development of the decalcomania within the last 5 years has been very great.

There are four gas-fired, square, muffle type decorating kilns, each having two chambers. Coal is fired on grates along each side. The temperature reached corresponds to cones 018 and 019. Where gold and color is used in the decoration the ware must be twice fired. Inspection and packing in sets complete the production feature.

Economic Factors Important in Pottery Manufacture

The American pottery industry is today in a far more advantageous position than before the war, but it is still subject to several important factors. One of these is the necessity of importing English kaolins and ball clays, which, contrary to the broad statements of chemists not thoroughly familiar with the industry, are essential to the production of tableware. Potters would be glad to use domestic materials if it were possible to do so and are even now introducing as much North Carolina and Florida kaolin as they dare to use. The position as regards ball clays is more favorable and it should be possible in time to eliminate a large part of the imported clays. Some of the Tennessee and Kentucky clays are already being used and recent developments in Missouri afford additional hope.

The great need is, however, for primary kaolins found in sufficient quantities and of good quality. The North Carolina kaolins at the best are extremely valuable materials, but unfortunately they are subject to variations due to their fluctuating mica content, which renders them more or less unreliable. Furthermore, the quantities available are not sufficient to supply the whole trade. The plastic kaolins of Florida and Georgia can be used in smaller proportions, but these offer real difficulties because of their fine-grained, partly colloidal nature.

It is to be hoped that the search for suitable kaolins will be continued until ultimately it will be possible to depend entirely upon domestic raw materials. As regards the flint and feldspar, we have an ample supply of these rocks.

Labor

The second important factor in the pottery industry is the labor question. Organized labor prevails and piece work is the rule. This system has both its advantages and disadvantages. It cannot be denied that labor has been unreasonable in the past, but this is true of all other industries. On the other hand, the Brotherhood provides the potteries with trained men who have served their apprenticeships and are skilled workers. This organization has also shown wise moderation during the recent wage settlement and the trouble that existed has been caused by "locals" not affiliated with the Brotherhood. The future development and growth of the industry will undoubtedly depend upon closer co-operation between the manufacturers and the craftsmen.

Educational Needs

One of the needs of the situation is an opportunity for the pottery workers to be trained in properly equipped schools in the technical fundamentals of the trade. Such a beginning has been made at the Trenton School of Industrial Arts and it will be necessary to found similar institutions at several of the clay-working centers. It is essential that an opportunity to improve himself be offered the ambitious workman. It cannot be expected that a large proportion of the potters would avail themselves of such training, but those who do will constitute the nucleus from which foremen and superintendents can be chosen. This has been realized for some time in Europe, where trade schools open to workers have been in existence for many years, and attention need be called only to the schools at Stoke-on-Trent in England, Levres in France, Bunzlau and Hoehr in Germany and Teplitz in Bohemia.

The writer is indebted to W. E. Wells, Jr., general manager, and A. V. Bleininger, chief technologist, for courtesies extended during visit to the plant and information furnished for the preparation of this article.

Chemical Warfare and the Arms Treaty

Abolition of Gas Warfare by Proposed Treaty Is Shown to Be Impractical and Not in Harmony With the Best Technical Opinion—Alternative Procedure Suggested to U. S. Senate and a Review of the Facts Upon Which It Is Based

By R. S. McBRIDE

IN THE TREATY on submarines and chemical warfare, the representatives of the five principal world powers have returned a signed indictment of the use in war of noxious gases and chemicals. Now it remains for the Senate of the United States to try the case of the indicted criminal, gas.

In this article there will be no attempt to propose just what the Senate of the United States should do with this particular treaty. The effort will be rather to set forth certain *established* facts and other *alleged* facts which should be taken into account by the Senate if this treaty is to receive proper consideration from the standpoint of the needs of the American people.

The following is the only section of the submarine treaty (so called because all other sections treat of submarines) which deals with the question of the use of gas. It is section 5:

> The use in war of asphyxiating, poisonous or other gases, and all analogous liquids, materials or devices having justly been condemned by the public opinion of the civilized world and a prohibition of such use having been declared in treaties to which a majority of the civilized powers are parties, the signatory powers, to the end that this prohibition shall be universally accepted as a part of international law binding alike the conscience and practice of nations, declare their assent to such prohibition, agree to be bound thereby as between themselves, and invite all other civilized nations to adhere thereto.

What Led to This Treaty Proposal

Strong public opinion against the use of gas in warfare developed spontaneously after the famous chlorine attack made by the Germans on the Canadian troops at Ypres. This sentiment grew steadily during the remaining period of the war and still remains a powerful factor throughout the country. As a consequence a few hundred thousands of the communications which came to Washington from individuals, associations and others during the late Arms Conference urged the abolition of the use of gas in war.

A technical sub-committee of the Arms Conference was appointed to represent the five principal powers affected. This committee consisted of seven members, two each from the United States and France, and one each from Great Britain, Italy and Japan. The advisory committee of the American delegation, consisting of a group of private citizens and public officials selected more or less as spokesmen of American public opinion, also gave consideration to the question of gas. It was on the basis of the reports of these two committees and of a third document submitted by the General Board of the U. S. Navy that the American delegation based its conclusion that gas warfare should be prohibited.

The full texts of these several documents have already been made public, but it is believed that their important bearing on the present situation warrants a brief review of their salient conclusions. It will be recalled that the representatives of the five signatory powers who acted as technical experts in the consideration of gas warfare were of the opinion that it was impractical to prohibit chemical warfare. The committee reported, among other things, that neither the research nor the production of warfare gases could be prohibited, restricted or supervised and that therefore "no nation dare risk entering into an agreement which an unscrupulous enemy might break if he found his opponents unprepared to use gases both offensively and defensively."

The American delegation and the Arms Conference itself, however, did not accept this technical interpretation of the situation. In this respect it departed materially from the policy which it apparently followed throughout all of the rest of its deliberations. In all other cases it appears that the Conference reached its conclusions on technical subjects after weighing carefully but finally approving the consensus of technical opinion. It certainly did so in the case of the conclusions reached with respect to submarines, aircraft and the exact disposition of naval vessels.

The Advisory Committee and Navy Reports

A sub-committee of the advisory committee, under the chairmanship of General Pershing, also labored over the matter, and its report was presented *in extenso* to the Arms Conference by Secretary Hughes. After reciting general statements as to the development of gas warfare, the committee concluded that "whatever may be the arguments of technical experts, the American representatives would not be doing their duty in expressing the conscience of the American people were they to fail in insisting upon the total abolition of chemical warfare, whether in the Army or the Navy, whether against combatant or non-combatant."

As a result of its deliberations, the American delegation adopted in substance this advisory committee report despite the fact that the advisory committee was far from unanimous in recommending it to the delegation. It is reported that the split on this particular resolution was, in fact, one of the most serious points of friction in the entire proceedings from the standpoint of the American advisers.

At this point there was injected into the discussion, "for the information of this committee," a report by the General Board of the U. S. Navy, which said categorically "Yes" in answer to the question, "Should gas warfare be prohibited?"

The comment of the General Board of the U. S. Navy cannot be regarded as a technical discussion of the question, but it appears to have had considerable influence with the delegation, possibly because it stressed the frightfulness of the use of gas against non-combatants.

The American delegation after considering these re-

ports laid before the Arms Conference a resolution which was presented by Mr. Root. This resolution strictly forbade in any way use of asphyxiating, poisonous or other gases, and all analogous liquids or poisonous devices. It was in substance identical with the final form of the treaty provisions quoted above. This resolution was adopted by the Conference unanimously and became the basis for its final recommendations which now are before Congress.

An Alternative Procedure Now Suggested

Those who have studied the subject carefully, particularly those who have had long experience and know gas warfare, believe that the conclusions of the Arms Conference were in error in their interpretation of the function of gas as a military weapon. They all admit that there are highly improper uses of gas, just as there are recognized misapplications of the submarine and aircraft. However, basing their conclusions upon certain facts, or alleged facts, they insist that the proper procedure would have been to define as clearly as may be the misapplication of gas, and provide penalty for such misapplication, rather than to have attempted to prohibit its use. In other words, they would place gas in the same category with submarines and provide correspondingly. One alternative which has been proposed uses the substance of the treaty above discussed and by re-wording it but slightly accomplishes this result in the following language. (The italicized words in paragraphs 1 and 2 and all of paragraph 3 are the new portions):

> The *wrongful* use in war of asphyxiating, poisonous or other gases and all analogous liquids, materials or devices having been justly condemned by the general conscience of the civilized world.
>
> The signatory powers, to the end that the prohibition of this *wrongful* use shall be universally accepted as a part of the international law binding alike the conscience and practice of nations, declare *that the use of these materials in any form against cities or against bodies of non-combatants of a belligerent or neutral country is a violation of the laws of war, and they* agree to be bound thereby as between themselves, and invite all other civilized nations to adhere thereto.
>
> The signatory powers do further declare that any person in the service of any power who shall use these materials in any form against cities or bodies of non-combatants shall be deemed to have violated the laws of war and shall be subject to trial and punishment as in the case of persons violating the rules adopted for the regulation of submarine warfare.

Six Pertinent Facts

In urging the adoption of this alternate form of treaty obligations certain important facts and opinions have been enunciated. It appears that the Senate of the United States should, and it doubtless will, carefully consider these points. They may be briefly summarized as follows:

(1) Gas as a military agency can be developed by research and its manufacture continued in secret indefinitely, if any nation wishes, despite any number of international agreements to the contrary. In this respect it differs fundamentally from battleships and fortifications, which cannot be so secretly constructed and preserved.

(2) Gas in its application in war can be as accurately controlled as to its objective as can high explosive, shrapnel or small arms missiles. It is urged that there is absolutely no justification for the claim that it necessarily is used against non-combatants as well as combatants if used at all.

(3) Gas is demonstrated to be the most effective and probably the most economical weapon; and it is claimed by those who have thoroughly studied the subject that it is fully as humane a weapon as any other. Assuming a demonstration of these three important points, gas would certainly qualify as one of the most acceptable potential weapons of modern war, even assuming that that war is to be a "civilized" one.

(4) The Chemical Warfare Service as a military agency cannot limit itself to offensive military preparedness, for it is essential to have at all times defensive measures provided for the protection of our troops in case an unscrupulous potential enemy might violate an international agreement.

(5) Effective preparation for defense against gas warfare demands thorough study of offensive measures that may be met. Moreover, the surest guarantee that offense measures will not be used contrary to agreement is the fear of retaliation on the part of the better prepared enemy. Thus it is argued that means for offensive warfare of this type must always be maintained not only on an experimental scale, but upon a scale capable of expansion to large units very quickly.

(6) The Chemical Warfare Service, furnishing as it does an important link in the chain of chemical industries, contributes to peace-time welfare of the community through this and other means quite sufficiently to justify its cost even though its military value as a measure of defense were entirely ignored.

Demonstration of these six points in convincing detail is out of place here. Some of them, as pointed out below, are easily demonstrable. Others have been less clearly established. Nevertheless they are set forth and insisted upon by those who should know and who probably can at the proper time bring forth evidence for their conclusive support. At this time, therefore, it is urged only that these facts and opinions be not ignored, but that effort be made to bring out all the points pertinent to them before this nation shall have irretrievably committed itself to a policy upon which there is still ample ground to justify difference of opinion.

Controllability of Gas

It requires no elaborate argument to demonstrate the unquestioned correctness of the first point made—namely, that research and development, even manufacture, of gas offense material can be continued in secret if desired. This research and development, in fact this manufacture, is going on as a part of regular chemical industry and will continue as such without regard to the military significance of treaty obligations. It is quite as hopeless to attempt pre-control by agreement of these things as it would be to attempt pre-control of the judgment of the commander of a submarine. The integrity of those in charge must be trusted to determine what use will be made of such facilities or of such submarine. Only the honorable character of these persons will determine what the application will be. Their existence cannot conceivably be prevented.

The controllability from the standpoint of who is harmed by use of gas is a question not quite so clearly established. Experiences of non-combatant populations subjected to gas are reported from the late war. That such experiences were not uncommon need not be questioned, but there is no question that non-combatants were similarly harmed by the misapplication of bombs and other explosives dropped from airplanes or by missiles of all types from small arms to the largest of high-explosive shell. Technical experts seem unanimous

in their statement that gas *can* be applied as accurately to an objective as can any other weapon.

An unscrupulous enemy might apply it to non-combatant as well as combatant. In fact, the advisory committee seems to fear this frightful and unrestrained use of gas, if it is permitted at all, more than any other feature. But there is no reason why there should be such application than there is that an enemy should sink passenger vessels unwarned or hospital ships traveling solely on errands of mercy. The choice is strictly his.

Effective, Economical and Humane

The large percentage of casualties experienced in the last war from gas is a complete demonstration that gas is one of the most effective weapons of modern war. The experience of the late war was also a complete demonstration that from the standpoint of money cost it is one of the most economical agencies of offense.

It is estimated that proper defensive measures for protection of America could be at least fifty to one hundred million dollars per year less if it were permitted that our Army and Navy use gas as one of the agencies against the combatants of an attacking enemy. It is insisted by those who have studied the subject that this tremendous annual saving could be accomplished even though the total expenditure for all Army and Navy agencies were only to be one-half to one-third of the present total, which is between one-half and three-quarters of a billion dollars per year. Unless the enemy can gain absolute control of the air, thus blinding our military forces in this element, and then be free to attack as he wills from the air, the defensive measures which can be accomplished by gas used upon landing places give tremendous advantage to a defensive force. The advantage is so great, indeed, that it is urged that other expenditures of all types could be materially reduced without it any way curtailing the effectiveness of the defense provided.

The third claim regarding gas as a weapon—that it is as humane as any other—is also demonstrated. It is shown that the percentage of recovery of gas casualties has been very much higher than the percentage of complete recovery from any other cause of casualties. Medical investigation seems to have established the fact that there is no justification for the assertion that tuberculosis, pneumonia and the other diseases claimed as after effects of gassing were so caused. It is also insisted that the suffering caused at time of casualty is no greater when a man has been subjected to gas than if he has been *equally* disabled by bayonet, shrapnel or high explosive.

Since it is upon the basis of humanity and humanitarian considerations that the decisions of the Arms Conference were reached, it would seem essential that this point should be thoroughly studied in the light of the latest and the best information which can be brought before the Senate of the United States.

Continuance of C.W.S.

The British representatives in addressing the Arms Conference were so outspoken in their interpretation of the proposed treaty that it seems there need be no doubt in the minds of the American people on the same point —namely, that the treaty does *not* mean any interruption of measures of preparedness from the standpoint of defense. It seems reasonable to assume, therefore, that the question of continuance of the Chemical Warfare Service as a branch of the Army is not raised by the discussion of this clause of the treaty. In any event, C.W.S. can be defended very convincingly as a defensive unit and as a unit of peace-time value quite worth its cost.

What Shall Be Done About It?

The Senate of the United States is already considering these treaties. The Senate is a deliberative body reaching conclusions after thorough consideration and serious debate pro and con. It would not be fitting or proper that the chemical industries of the country, which have the most intelligent appreciation of the present situation, should take the initiative and attempt to dominate this situation, even on the ground of the superior knowledge of the question. The matter is one of public policy and public opinion, rather than of science and technology.

Despite this limitation which expediency places upon the chemical industry at this time in this matter, the industry can and should insist that the Senate carefully bring out all facts bearing upon the usefulness, the "frightfulness" and the humanitarian aspects of gas warfare.

If the Senate will carefully and thoroughly delve into the subject, there is no question that it will reach a sound and proper conclusion. Whether this conclusion will be to ask the President to negotiate a slight amendment of this section of the treaty, whether it will be to accept the treaty with clear understanding in their own minds as to what limitations must inevitably be placed upon its meaning, or whether the flaws alleged to exist will be deemed sufficient to cause rejection of the treaty as a whole and insistence that this section must be omitted before ratification, only time can tell.

If, as is urged by some, the conclusions of the Arms Conference were based upon a misunderstanding of the facts, then the Senate can well take some course leading to appropriate amendments of the Conference recommendations. However, to urge this now would be quite unseemly, for some of the greatest minds that present-day statesmanship can furnish have studied these questions and reached deliberative conclusions. All that can or need be asked is that the review of the situation by the Senate be thorough and impartial.

Investigation of Abandoned Magnesite Beds

Previous to 1860, most of the epsom salts used in the United States was made from magnesite mined in Pennsylvania. The demand for magnesite on the Atlantic seaboard resulted in an investigation by the U. S. Geological Survey as to the possibility of again working the Pennsylvania deposits profitably.

The work done, which consisted of re-excavating the pits, quarries, open cuts and a shaft that had become filled with dirt, showed that the magnesite occurs in a fine network or stockwork of small veins, most of them less than an inch thick. Two veins were uncovered, one about 14 in. wide and the other about 12 in. wide. A thorough exploration, including the reopening and drainage of a shaft with underground drifts, failed to disclose any larger veins, but it is reported that a body of magnesite about 30 in. wide was found in the shaft at the crossing of two principal veins.

The development work completed last fall shows that the quantity of magnesite available close to the surface is very small and that many tons of waste would have to be handled to produce a single ton of ore, and production on a commercial scale was therefore not attempted.

Centrifugal Casting

An Art Known for Over a Century—Requires Careful Adjustment of the Cooling Rate, Which Is Controlled by the Temperature of the Mold and of the Liquid Metal—Recently Adapted to Steel and Monel Metal

By L. CAMMEN

IN THE present paper it is intended to describe the process of centrifugal casting of hollow metal objects. Actually, however, centrifugal casting has been successfully applied to the production of non-metallic tubes, such as concrete pipe (Hume process). It has also been used for the production of solid castings, by locating the molds around the rim of a spinning wheel. By this method dense aluminum castings have been obtained, as well as concrete blocks and precast shapes.

The Art Is Old

The art of centrifugal casting of hollow metal objects is quite old, and has been practiced on a commercial scale in England since the beginning of the last century, the earliest patents dating as far back as 1809. About the year 1852, Shanks, in London, made cast-iron gas pipe, 12 ft. long, 3 in. in diameter, by pouring molten metal into a spinning wrought-iron mold. He also applied his process to the manufacture of iron sheets for roofing, by casting cylinders, 9 in. long, 6 in. diameter and about 0.01 in. wall thickness. These cylinders were then carefully annealed, cut open and flattened out. The process was kept secret, and these sheets found a ready market for a long time, until rolled-steel sheets became available.

As noted in the *Mechanic's Magazine* for December, 1864, Whitley and Bower, in England, applied the process of centrifugal casting to the manufacture of cast-iron wheel tires. Their machine is shown in Fig. 1,[1] where *A* is a metal, clay-coated mold rotating about a vertical axis *B*. The metal is supplied through spout *C*, while *D* and *E* are the fast and loose pulleys by means of which the rotary motion is imparted to the mold. In its essential features the Whitley machine does not differ from the majority of those used today, at times under the veil of the deepest secrecy, in this country and elsewhere.

That the art of making centrifugal castings was known in the United States at an early date—that is to say, early in our industrial history—is shown very clearly by an illustrated description in one of the first issues of the *Scientific American*. Fig. 2 reproduces this page and the description, which exhibits the state of the art so well that comment is superfluous.

Sir Henry Bessemer, the inventor of the bessemer process of steel manufacture, devoted a good deal of his attention to the subject of centrifugal casting of steel, without, however, publishing full details of his trials. M. Tresca, in a paper before the Institution of Mechanical Engineers (1867, pp. 149-50), states, however, that "the most remarkable instance that he had met with of freedom from air bubbles was in the case of a bessemer rail manufactured at the Imphy Iron Works, near Nevers, in the Department of Nièvre; and he had ascertained that the method adopted at these works was to pour the molten metal into a revolving vessel driven at a considerable speed, so as to clear the steel of air by rapid rotation. This method appeared very effective in practice, in freeing the steel from the minute air bubbles which it contained on leaving the converting vessel or the melting pot."

In 1882 Webb, speaking before the Iron and Steel Institute (*Journal*, 1882, p. 522), stated that at his works in Crewe he was casting steel wheels and making them sound by casting them on turntables. Not only this, but he used a variable speed and feed in doing so. His remarks show that at that time the mechanics of the centrifugal casting process was already perfectly well understood, a supposition further supported by the fact that Ledebur's "Handbook of Iron and Steel Founding," published in 1892, devotes a chapter to centrifugal casting, covering all the fundamental elements of this art.

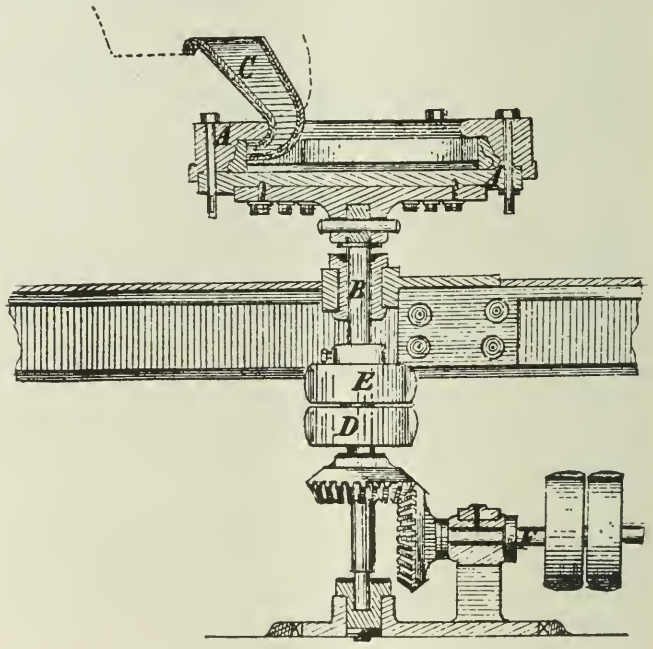

FIG. 1—WHITLEY AND BOWER (1864) MACHINE FOR CENTRIFUGALLY CASTING TIRES FOR WHEELS

A study of these references and the numerous patents issued on centrifugal casting in this country and in Europe would indicate that practically all the essential features were covered by patents issued prior to the beginning of the twentieth century, so that with the exception of minor details and one or two features in special casting processes there is no reason why any good engineer could not design a successful casting machine without running into legal complications. A

[1] Reproduced from *Dingler's Polytechnic Journal*, vol. 153, p. 451.

familiarity with the patent situation is, however, desirable in order to avoid involuntary infringement by using some minor detail (such as, for instance, a particular type of pouring spout) that has been covered by a patent.

Field of Application

It is only within the last few years that the field of application of centrifugal casting has begun to be realized. As a matter of fact, it is very extensive indeed and falls into several regions. In the first place, centrifugal casting is a cheap method of producing goods of certain shapes—namely, those having a hollow interior, symmetrical about an axis passing through the body of the casting, whether concentrically or eccentrically. The advantage of such methods lies in the fact that with proper equipment a very large number of units can be produced with comparatively little labor and without the use of cores. During the war several concerns employed this method—for example, for the production of piston rings for automobile engines—and even now establishments like the Ford Motor Co. employ it regularly with considerable success. An American manufacturer of bearings uses the centrifugal method to line the tube with the bearing metal. The Sandusky Foundry & Machine Co., Sandusky, Ohio, employs such casting to produce big paper mill rolls and propeller sleeves which would be much more expensive and probably less satisfactory if cast in a stationary mold. The same method with slight modifications has been applied to the manufacture of hollow tubes of variable cross-section, which could not be cast at all in a stationary mold and would be very expensive to produce by machining.

However, the above is not the most important field of application of centrifugal casting, the value of which lies primarily in the fact that by its means shapes can be produced which it would be next to impossible to produce by casting in stationary molds. Thus the Stokes Castings Co., Ltd., Mansfield, England, has produced by this method cast-iron liners for aluminum cylinders for airplane engines of such a small thickness and high grade of metal as could not be duplicated by any other process except by machining, and at a price only a small fraction of what a machined tube would have cost.

As a matter of fact, centrifugal casting in many cases produces a metal essentially different from the one produced by casting in a stationary mold, whether sand or chill, and approximates more the character of a forging. Thus tests made on centrifugal steel castings by Dr. G. K. Burgess, of the U. S. Bureau of Standards, have shown that centrifugal castings properly heat-treated can pass with a safe margin all requirements of the Ordnance Department specifications for gun forgings, which is certainly a very remarkable thing. Those who deal with thin-wall Monel metal castings know how extremely difficult it is to obtain solid metal free from blowholes and miniature "pipes" or cavities caused by unequal contraction. And yet Monel metal tubes 2 to 3 ft. in length and $\frac{3}{8}$ in. in wall thickness have been produced centrifugally of such uniformity of metal as to permit drawing them into perfect seamless tubes.

FIG. 2—A PAGE OF THE "SCIENTIFIC AMERICAN" OF 1849

Centrifugal Casting vs. Piercing

Hitherto the principal tonnage of seamless tubing has been made by the Mannesman piercing process and its variations. Essentially this process consists in imparting such a twisting motion to a steel billet as to break down its central fibers, a motion set up by means of obliquely placed rolls or disks. This works very well with high-grade mild steel or Muntz metal, but does not work well with metals which are either extremely tough or very brittle. Thus all efforts to produce pierced Monel metal or Admiralty brass billets have so far been unsuccessful commercially. Because of this limitation of the Mannesman process there are a considerable number of metals and alloys not used today for the production of seamless tubing. Notwithstanding the large demand for high-carbon chromium (1.25 C, 1.5 Cr) steel for ball-bearing races and the fact that it would be obviously desirable to make these races out of seamless tubing, they are made out of a solid bar, either by direct machining or by the trepanning process, at a considerable increase in cost over what it would have cost to make them out of tubing. The reason for it is that high-carbon chromium steel of the above analysis cannot be pierced by the Mannesman process easily enough to permit of its commercial production. Not only that, but Mannesman's process is limited to the production of comparatively small sizes, not in excess of, say, 6 in. in diameter (although tubes as large as 9 in. have been produced more or less experimentally). It is obvious that as we go up in sizes both the piercing mills and the drawing benches used in this process increase in size and cost with great rapidity.

The centrifugal process permits one to cast, at a comparatively moderate cost, seamless tubes in sizes

practically without limit. For example, there is no reason except our still insufficient knowledge of the details of the process why tubes 10 ft. in diameter and, say, ¼ in. wall could not be made thus.

It has particular application to the production of condenser tubing from Admiralty brass (10 per cent Cu, 29 per cent Zn, 1 per cent Sn). Hollow billets from this mixture cannot be made by the Mannesman process and therefore have to be cast in sand using a core soft enough to permit the metal to contract. Not only does this necessitate the use of excessively thick walls (⅝ in.) in order to produce a good casting, but such thick walls also require an excessive number of draws in the bench, with a corresponding increase in the cost of the final product. Furthermore, one can never be certain of the behavior of a soft core and no two castings are absolutely alike, some of them containing blowholes, cavities or hard metal. Moreover, in sand casting there is no positive way to eliminate slag inclusions or bits of sand from the mold or core being captured by the metal. Every blowhole, cavity or slag inclusion means a weakness or failure of the tubing, and none of them can be discovered as a rule until a number of draws have been made on the tube and a considerable amount of money and labor spent. Centrifugal casting in a mold with properly controlled temperature permits one to produce practically perfect Admiralty brass tubes in thicknesses of ⅜ in. and down to 1/16 in. with a higher degree of certainty than from sand-cast tubes. Moreover, such tubes have been found to be practically free from occluded slag or hard spots.

Another remarkable feature of centrifugal casting is its ability to produce very close mixtures where sand casting results in a great deal of segregation. One of the most striking examples of it is in the casting of lead-copper alloys. When cast in a sand mold the copper segregates from the lead to such an extent that the two metals can be clearly distinguished in yellow and dark gray banding. When cast centrifugally at proper temperatures a uniform blackish gray alloy is produced and the particles of copper and lead cannot be seen by the naked eye (but are fairly clearly distinguishable under a microscope). On the other hand, when casting bronze in a spinning mold, there does occur a certain degree of segregation resulting in an increase of hardness with a corresponding percentage of tin toward the inner edge. It would appear, therefore, that the action of centrifugal force affects some metals more than others, which may be due either to the electrical potential between the two metals or to the method by which the metals in the alloy are combined—that is, whether they form a chemical compound, a solid solution or a mechanical mixture—and possibly by the proximity of the analysis to the eutectic. It may be mentioned in this connection that all attempts to separate silver out of a lead-silver alloy by centrifuging have failed, notwithstanding very high speeds employed.

Mechanics of Centrifugal Casting

In the first place, clear distinction should be made between castings made with a horizontal and a vertical axis, and also with the intermediate case of an inclined axis. In casting about a horizontal axis the metal is distributed symmetrically about the axis, and if the axis of rotation coincides with the axis of the spinning unit, a tube of uniform thickness is produced for the entire length of the mold. If a vertical axis is used, it is obvious that the external wall of the casting follows the shape of the mold, while the interior of the casting forms a paraboloid of revolution, the elements of which, in accordance with the formulas developed by Resal and Kirpicheff, depend on the speed of rotation, the specific gravity of the metal and the depth of the mold. In casting with an inclined axis, the same general principles apply with the further complication that the elements of the inside paraboloid of revolution are also affected by the angle of inclination of the axis to the true horizontal.

Two methods may be used in producing centrifugal castings. The one ordinarily used is to introduce

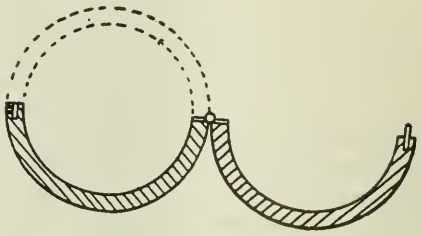

FIG. 3—SECTION OF MOLD SPLIT ALONG THE LONGITUDINAL AXIS (THE TWO PARTS MAY BE EITHER HINGED OR BOLTED)

molten metal into the moving mold. The other is to melt the metal in the mold in which the casting is made. While this is a convenient scheme to effect certain conditions—as when it is desired to keep the metal from coming in contact with air—it has been so far applied only on a limited scale.[2]

A mold for the manufacture of tubing and pipe may be either solid or split (Fig. 3). The latter is preferable when long pipes are cast, as it is then easier to shake out the pipe. Crucible graphite or zirconium

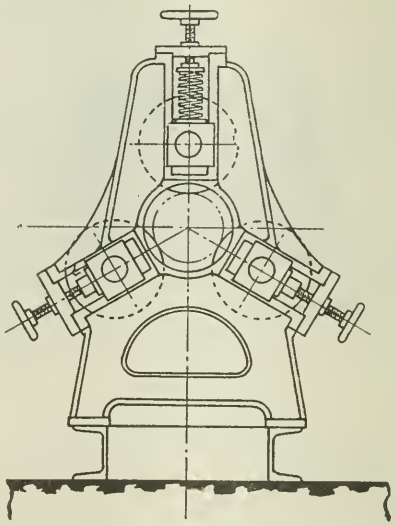

FIG. 4—SPINNING BENCH FOR USE WITH REMOVABLE MOLD

tubes may be used for molds for short castings, but when casting long pipe, metal molds are to be preferred, especially those made of such a heat-resisting and noncorrosive alloy as nichrome. Enough work has been already done on the production of cast tungsten to make it certain that a mold of this truly wonderful material will be available within a comparatively short time.

There are several ways of supporting the mold in the spinning bench (Fig. 4), the selection of which de-

[2]For its description see "Mold Serves as Electric Furnace," by E. C. Kreutzberg, *Iron Trade Review*, July 7, 1921.

pends mainly on the size of the unit. But there is one rule which must not be forgotten for an instant by the designer of a machine for centrifugal casting, and that is that it should be made substantial, strong and free from vibration, which means a well-balanced rotator on a solid foundation.

If molten metal is to be poured into the spinning mold, very careful consideration of the thermal conditions in the mold and of proper appliances for handling the hot metal will be required. It may be added that one of the most important reasons why centrifugal casting has not been used to the great extent which it deserves has been the failure to appreciate properly the necessity of keeping the mold at the *proper* temperature, be it high or low, and the consequent failure to produce sound articles.

Heating the mold may be done electrically if very cheap current is available. Otherwise the mold is heated in the same type of furnace as is now used for heating billets at tube mills, while small molds may be heated by placing them in the flue of a reverberatory furnace. For casting such metals as steel and Monel, the mold should be heated to about 2,200 deg. F., so as to reach the spinning bench with a temperature of about 2,000 deg. F.

Where a metal mold is used, it should be coated with a thin film of some material which prevents the metal of the casting from coming into direct contact with the metal of the mold. There are several materials that may be used for such coating, and their selection depends largely upon the metal to be cast. I may mention here electrically calcined magnesia with pitch as a binder; zirconia with either pitch or crucible clay as a binder; and plain pitch, which can be used only with non-ferrous materials except with alloys rich in nickel.

The life of the mold depends on its material and handling. Thus far nichrome appears the most long-lived material now available. Under conditions very similar to those under which these molds work, cast nichrome has shown a life of from 10,000 to 12,000 hours, the time required to make about 20,000 castings. Under certain conditions it may be found cheaper to use alloy iron molds with nichrome liners. If the outer shell of the mold is made of iron containing about 7 to 10 per cent Cr and 2 per cent Ni, the life of the mold will be as high as 1,000 castings. Selection of the type of mold is determined largely by considerations of cost and the heating furnace available.

Function of Riser or Sink-Head

We should consider first steel or Monel metal castings, since they present more difficult combinations of conditions than either brass or bronze. In making castings in a stationary mold, whether it be a simple ingot or a complicated casting from pattern, the foundryman has to provide for the escape of gas from the metal and for the piping produced by contractions in cooling. In a casting from a pattern, the gates or risers are so proportioned as to avoid defects from these causes. In ingot casting, special methods such as dozzling are used to keep the top of the ingot hot as long as possible and thus provide opportunity for the escape of gases, and furnish hot metal to fill in the contraction cavities, the topmost part of the ingot thus performing the functions of the risers in sand molds. In both cases the foundryman is prepared to discard as defective a certain part of the casting (the ingot head, gates and risers) and his skill lies partly in reducing the quantity of defective parts as far as possible, and especially in directing the process so as to get all the defective metal into the parts which he can discard without spoiling the casting.

In centrifugal casting, however, there is no riser or anything corresponding to the ingot top, the cooling proceeding essentially at a uniform rate all along the length of the tubular shape. It is obvious, especially in tubes of small diameter and considerable length, such as 6 in. outside diameter and 16 ft. long, that the loss of heat inward must be extremely small, because the entire inner air cylinder is surrounded by metal at approximately the same temperature. Heat is therefore lost outward to the mold and through it to the air. As a result of this, the part of the casting in immediate contact with the mold chills first. At first sight, especially to those familiar with such centrifugal processes as cream separation, it would appear that the pure metal, being heavier than either slag or oxidized metal, should be thrown to the outside, while all impurities and metal containing dissolved gases would be forced to the inside. This does actually happen, providing only sufficient time is available. But this separation takes place at a fairly slow rate because of the great viscosity of molten steel. If enough time is available between the instant of casting and that of complete freezing of the metal, the impurities and gases *will* be thrown out to the inside of the casting, otherwise they will be caught in the tube wall and make the tube worthless. This is one of the reasons of the many past failures to produce thin-wall steel tubing by centrifugal casting. On the other hand, very excellent steel tubes (both plain carbon and nickel alloy) have been produced with diameters ranging from 10 in. up and wall thicknesses up to 3½ in. In the latter case there is so much metal in comparison with the area in contact with the mold that enough time is available to produce a good segregation of impurities inward before the inner wall freezes.

Thermal Conditions in the Mold

It would appear, therefore, that the secret of producing tubing of thin-metal (under ½ in.) lies in establishing conditions under which the cooling of the molten metal would proceed at a fairly slow rate. In the Cammen process this has been accomplished by preheating the mold to a temperature fairly close to the melting point of the metal itself, as, for example, to 2,000 deg. F. for steel and Monel metal castings. Under these conditions a ⅜-in. wall takes about 60 seconds to harden entirely, which is sufficient to produce clean metal.

Brass casting shows the same phenomena, though, of course, to a somewhat lesser degree, because of the lower melting point of the metals and the ability to superheat them to a somewhat greater extent than is possible with steel. Nevertheless, even there the chilling of the metal is one of the most serious difficulties that has to be overcome by the manufacturer of centrifugal castings. Attempts have been made by several manufacturers to introduce the entire metal of the casting at once, which involves the use of elaborate and so far only moderately successful pouring devices.

The problem of the centrifugal tube maker, working in bronze is somewhat complicated by the fact that he is between the devil and the deep sea, and cannot even directly resort to the Cammen expedient which proved satisfactory with steel and Monel metal—that is, the use of the hot mold. If he chills the bronze very

rapidly, he generally gets an excellent metal, but is apt to run into trouble because of the presence of blowholes due to occluded gases. Unless the metal is poured into the mold at such a rate as to form a complete section when casting heavy tubes by this process, the first metal poured chills, and then when new metal is added it does not weld completely to the previous batch, the result being a composite tube or one with split areas in its interior. These defective tubes give considerable trouble, especially under a hydrostatic test. This is probably the main reason why manufacturers of centrifugally cast bronze tubes refuse to sell rough castings; not being certain of their product, they prefer to eliminate defective tubes in their own plants rather than have their customers do it. On the other hand, if the maker chills the metal very slowly, using a hot mold, he gets rid of the danger of blowholes, but the bronze is coarse grained and will not satisfactorily pass the hydrostatic test. In the Cammen process this dilemma has been solved by the employment of a somewhat complicated but effective system. The bronze is poured against a hot mold (electrically heated to a temperature about 100 deg. below the melting point of the particular bronze), but as soon as the pouring has been completed a stream of water is passed over the mold, which chills it as rapidly as may be desired. In this way the temperature conditions during cooling can be controlled to accord with the best practice for the given metal.

Cast-Iron Pipe

Cast iron is in many respects different from that of the other metals, in that numerous tests have shown that the best results are obtained when cast iron is cast against a chill mold. Methods for making cast-iron pipe in rotating permanent molds have been developed by a French-Brazilian engineer, Dimitri Sensaud de Lavaud, whose work has been of pioneering importance. The method developed by de Lavaud is novel and ingenious. He uses a cast-iron mold, water cooled on the outside, and a pouring spout extending to the farther end of the mold and moving at a predetermined rate of speed outward. As the metal is poured, it chills almost instantly and by the time the spout is withdrawn the entire tube is formed. As the metal is cast against a chill, it is a quite brittle white iron, but after a proper anneal it becomes tough. Because of its great uniformity, centrifugally cast pipe may be a good deal thinner for the same strength than pipe cast in sand molds, the ratio being approximately 15 to 23 lb. per ft. in favor of the centrifugally cast pipe.

Stokes Castings, Ltd., developed another ingenious method of rapidly chilling the cast iron for making piston rings and liners for aluminum cylinders of airplane engines. This concern uses a mold composed of a cast-iron liner with a heavy aluminum jacket, the selection of aluminum being apparently due to the fact that it has a specific heat more than four times that of cast iron and also a higher coefficient of radiation.

Steel Pipe and Centrifugal Casting

The field of national importance which is apt to be profoundly affected by the development of centrifugal casting is that of steel pipe, whether welded or seamless.

In the last 10 years or so there has been a remarkable extension in the applications of pipe. It is now used as a starting point in the production of a great many types of mechanical elements, such as shafts and columns. While similar members made of bar stock are usually produced in alloy steels, such as nickel, chromium-nickel, chromium-nickel-vanadium and tungsten, the same members when made of piping are of plain carbon steel. The reason for this is that piping is available only in simple steels. Although alloy steel tubing can be produced by the Mannesman process in a more or less experimental manner, and in fact has been produced on a comparatively small scale by the National Tube Co. in this country and Accles, Pollock & Co. in England, it has not yet really become a commercial product, and has seldom been specified by designing engineers. The initial difficulty in the production of this tubing lies in the piercing process. But hollow billets can be easily produced by centrifugal casting at a cost which compares not unfavorably with that of piercing, and the subsequent drawing from a hollow billet is easier than from a pierced billet, since the former is made of metal which has not been strained beyond its elastic limit.

A still more important future development will be centrifugally cast pipe in sizes from 6 in. up. While such sizes can and actually have been made in seamless tube, the machinery and processes employed for these sizes are so expensive as to make it impossible to compete with welded pipe except in very special instances. Because of this, welded pipe from about 6 in. up, and riveted pipe in still larger sizes, is practically standard. Casting in a hot spinning mold permits the production of pipe in all sizes at a cost estimated to be in the neighborhood of $40 per ton for standard thicknesses, and down to $35 or possibly less for extra strong and double extra strong. That seamless pipe at this price is preferable to welded pipe for the majority of applications need hardly be proved. If it is remembered that the cost of a plant per ton of produce to make centrifugally cast pipe is very much lower than that of either seamless or welded pipe, it will be clear what effect the new process may have on an industry now producing close to 3½ million tons of steel goods.

New York City.

Prices of Portland Cement in 1921

Preliminary estimates made by the United States Geological Survey from reports of representative producers of portland cement show that the average factory price per barrel of portland cement, excluding cost of container, in the United States in 1921 was approximately $1.87. The prices by districts were as follows:

District	Average Factory Price per Bbl.
Eastern Pennsylvania and New Jersey	$1.72
New York	1.90
Michigan and northeastern Indiana	1.85
Illinois and remainder of Indiana	1.68
Western Pennsylvania and Ohio	1.73
Maryland, Kentucky, Virginia and West Virginia	1.83
Alabama, Tennessee and Georgia	1.94
Iowa, Minnesota and Missouri	1.77
Kansas, Nebraska, Oklahoma and Texas	2.15
Colorado and Utah	2.33
California	2.35
Washington, Montana and Oregon	2.51

New High Explosive Reported

A new high explosive called brazilite is reported to have been discovered in Brazil. In experiments this explosive resisted without deflagration all mechanical and chemical tests. Assistant Trade Commissioner Bernard H. Noll in the Feb. 6, 1922, issue of *Commerce Reports* states that it is claimed that the explosive does not give off gases prejudicial to the operator. During the experiments 5,650 g. was placed in a bored hole 4 m. 65 cm. in depth, and this charge, when detonated, displaced 200 cu.m. of granite.

The German and American Synthetic-Ammonia Plants*—III

Description of Processes and Apparatus Used at Oppau, Germany, and Sheffield, Ala., for the Removal of Carbon Dioxide and Carbon Monoxide and the Additional Purification of the Gases Required for the Ammonia Synthesis

By R. S. TOUR

THE first undesirable constituent to be removed from the converted gas is the carbon dioxide, which is eliminated by water scrubbing of the gas under pressure. The pressure used at Oppau is but 25 atmospheres for the water scrubbing, although 200 atmospheres is the pressure used throughout the rest of the process. The compression is accomplished by 12 five-stage compressors (3-9-25-70-200 atmos.). After the third stage the gas is withdrawn and scrubbed, and then returned to the fourth and fifth stages. The compressors require about 1,000 hp. each, and are separately driven by direct-connected producer-gas engines. The compressors are of standard design with equal capacities in all stages, but since water scrubbing after the third stage removes about 35 per cent of the gas (CO_2 and some H_2 and N_2) there are provided 5 additional three-stage (25 atmos.) compressors to handle the larger capacity necessary in the power stages before water scrubbing.

Carbon Dioxide Removal at Oppau

There are 12 water-scrubbing towers, 4 ft. in outside diameter and 40 ft. tall, made in two 20-ft. sections, bolted together in the middle. All operate in parallel, taking compressed gas from a manifold fed by the 17 compressors previously described. The gas passes up through the tower packing, consisting of Raschig stoneware rings (3 in. by 3 in.) while water flows downward through the packing to a reservoir at the base of the tower. The exit gas from each scrubber passes through a mist trap or catch-pot before passing on to the fourth stage of the 12 high-pressure compressors. The mist trap is bottle-shaped, 5 or 6 ft. long, with the gas inlet tube extending some distance down into the bottle. (See Fig. 6.)

At normal capacity, about 3,000,000 cubic feet per day of scrubbing water is pumped to the 12 towers by 6 centrifugal pumps direct connected to motors (180 kw., 1,480 r.p.m.). On the same shaft is connected a Pelton-type water wheel through which the exit water from the towers discharges and returns about 60 per cent of the input water; the motors furnish the difference. Each pump and water-wheel set serves two towers, although there is a manifold cross-connecting all sets. The water feed to the Pelton wheel is controlled manually with the aid of a sight gage which indicates the level of water in the tower. Automatic float chambers for maintaining the proper water level and rate of discharge have recently been developed. The carbon-dioxide gas released in the water wheels passes to a holder for use in the ammonia utilization processes.

The gases liberated from the discharge water represent nearly all of the carbon dioxide in the original gas; the scrubbed gas carries less than one per cent. All of the hydrogen sulphide and similar constituents are also removed. The solubility of the other gases is not negligible and experience at Oppau indicates that 7 to 8 volumes of hydrogen and nitrogen are dissolved while removing the 28 to 29 volumes of carbon dioxide. This absorption of hydrogen and nitrogen is about twice that called for by the available data on relative solubilities, but is in accordance with experience at Sheffield. It is interesting to note that the loss of hydrogen and nitrogen in the water is rather independent of the pressure at which the scrubbing is done, since the ratio of solubilities of the gases is not greatly affected by pressure.

Carbon-Dioxide Removal at Sheffield

Carbon dioxide was absorbed at Sheffield at 100 atmospheres pressure, which was the pressure maintained throughout the rest of the process. The compression was accomplished in the operating unit by one (and one spare) 4-stage compressor (4-12-35-100 atmos.) with 700 cu.ft. per minute low pressure displacement. After allowing for water vapor in the gas, normal gas losses in scrubbing and purification, later "purge" of gas in the circulating system, and unavoidable but expected leakage, this displacement has a capacity of but 5 tons of ammonia per day. The compressors were belt driven by 300 hp. motors and operated very satisfactorily.

The original plan and installation was for water scrubbing the gas in three stages, the gas passing up through each of the three towers consecutively while fresh water was pumped to the top of each tower, fed downward through the packing, and was discharged into a common manifold. Such an arrangement for 3-stage scrubbing is fundamentally inefficient. It is evident that the water in the first tower will dissolve

carbon dioxide with a maximum solubility corresponding to the initial partial pressure. The unit absorption capacity of the water in the second tower will then be decreased due to the decreased partial pressure of carbon dioxide and finally in the third tower the solubility coefficient will be very low. In other words, at a given total pressure the quantity of water necessary to dissolve a given weight of carbon dioxide increases with any decrease in the percentage of carbon dioxide. Thus, if instead of absorbing the carbon dioxide in three stages, it were all absorbed in one tower of sufficient capacity, all of the water would be used under optimum conditions. The latter operation may require but half the water of the former, and in addition will proportionately decrease the loss of the valuable gases by solution in this water. The attempted operation at Sheffield also involved many mechanical difficulties in the control of the parallel water supply and discharge from each of the towers. After two months of experimentation two of the towers were superimposed, making one tower 2 ft. in inside diameter and 30 ft. high. One-stage scrubbing in this tower led to very satisfactory results, leaving less than one-tenth of 1 per cent of carbon dioxide in the gas. The exit gas passed through a catch pot to separate suspended water before passing to the next step of the process. (See Fig. 7.)

The packing in the towers is of prime importance for efficient scrubbing, since it is essential that it affords much contact surface, causes turbulent flow of the gas, does not pack or mesh together to cause channeling of the fluids, and, finally, is resistant physically and chemically to the action of pressure and corrosion. At Sheffield, spiral tile were first tried, then pipe nipples, large hard pebbles, and special coke, but these were all found unsatisfactory. Finally small castings of special, though simple shape, were developed and proved successful.

The water was fed to the tower by one (and one spare) reciprocating motor-driven pump of 20 cu.ft. per minute displacement. The water discharge from the tower was through a Pelton water wheel driving a generator which fed into the power line. The water wheel operated on water at 1,500 lb. pressure and carrying about 20 volumes of dissolved gas. It was the source, therefore of much trouble; at its best it returned but 25 per cent of the power in the water. The carbon dioxide released was discharged to the roof, and the water passed to the sewer. No utilization of the carbon dioxide was considered.

The question as to what pressure should be used for water scrubbing is one to be decided according to the conditions at the plant concerned. The quantity of water handled, of course, decreases with increase of pressure, since the solubility of carbon dioxide increases. The power required to pump the water is, however, not much affected, since as the quantity decreases its pressure head increases. Power recovery from the discharge water is much improved at the lower pressures, the main difficulty at very high pressure being due to the high nozzle velocities and the large quantities of gas expanding out of solution in the nozzle. Further, all the power required to compress the carbon dioxide to the scrubber pressure is a loss which is reduced by decreased pressure. High pressure scrubbing decreases the size of the apparatus, since the volumes of gas and water are decreased proportionately while the velocity of absorption is increased. The advantage of smaller apparatus is, however, somewhat offset by the necessary increased strength of the vessels and joints. These considerations in general point to a comparatively low scrubbing pressure (i.e., 200 to 500 lb. per sq.in.).

Carbon-Monoxide Removal at Oppau

As previously stated, the exit gas from the 12 water scrubbers returns to the 12 high-pressure gas compressors and is compressed to 200 atmospheres. The balance of the process beyond this point operates at this pressure. The next step consists of scrubbing the gas with a copper solution; the gas passes through scrubbers similar in operation to the water scrubbers, but using ammoniacal cuprous formate solution (containing perhaps some carbonate) at ordinary temperatures as the dissolving medium. Refrigeration of the solution and absorption of the carbon monoxide at low temperatures has apparently been tried at Oppau and abandoned. There are 15 towers, arranged in two sets (of 7 and 8 each), and situated in one row along the outside of the compressor building. (See Fig. 8.) Any tower can be cut out and it is probable that one item in each set is a spare. The towers are steel forgings about 40 ft. high and 1½ ft. in inside diameter, with walls 5 in. thick. They are heterogenously packed with iron Raschig rings (1 by 2 in. in diameter). A mist trap, similar in construction to that used in the water scrubbers, is employed at the exit of each tower.

Control of the Copper-Solution Scrubbers

All of the towers operate in parallel, the flow being manually controlled with the aid of sight gages. The gas inlets and exits of the scrubbers are cross-connected by a manifold and the operating valves are controlled from the inside of the building adjoining, the stems of the valves extending through the walls. There are friction orifices at the entrance of each tower for measuring the flow of gas, and the pressure differences are observed by means of a pressure balance of special construction. The device consists of a mercury U-tube of high pressure pipe, bent to a semicircle. This circle is suspended at its center on a knife edge with pressure connections of spiral flexible metal tubing leading from the center. A tendency to change the level of the mercury swings the U-tube and an adjustable counterweight about the knife edge. A pointer attached to the apparatus operates on a calibrated scale or a recording device.

The cuprous formate solution is pumped into the top of the scrubbers by 15 tandem-steam-driven pumps cross-connected in pairs (two pumps per flywheel). The solution passes from the bottom of the scrubbers to pressure release vessels, of which there are two, one for each set of towers. The spent solution, after release of the pressure, passes on to a large regenerating system where its carbon monoxide is removed by heating the solution under vacuum in regenerating vats, which are 20 ft. high and 16 ft. in diameter. The composition of the solution is readjusted before it is again used. The effluent gases from the generating system contain perhaps 50 per cent of carbon monoxide, the remainder being largely nitrogen, hydrogen, and ammonia. This mixture during the war was purified by additional ammoniacal copper solution and then piped to Ludwigshafen for the manufacture of phosgene, which was one of the most important of the poison gases.

Scrubbing the gas with the ammoniacal cuprous solution removes, by reaction with the reduced copper, any free oxygen that may be present; by combination with the free ammonia it removes the residual carbon dioxide as well as traces of other acidic gases that may have passed through the water scrubbers; and it absorbs nearly all of the 2 per cent of carbon monoxide in the gas. In normal operation about 35,000 cu.ft. per day of copper solution are passed through the towers, removing the carbon monoxide of the gas down to a few hundredths of one per cent. There is dissolved perhaps one per cent of the nitrogen and the hydrogen, which is liberated with the carbon monoxide on the regeneration of the solution. The absorption capacity of the solution for carbon monoxide is about 20 cu.ft. (60 deg. F. 30 in. Hg) per cu.ft. of solution, and regular operation approximates full saturation. There was, therefore, available at Oppau about 650,000 cu.ft. of carbon monoxide per day.

The question naturally arises why the copper scrubbing should be done at 200 instead of 25 atmospheres pressure. The mechanical construction would certainly be simpler for the latter. This case is different from that of the water scrubber. The power loss due to dissolved gas is slight and the energy requirement for the solution is small, so no attempt is made to recover the power. Further, the completeness and efficiency of purification is greatly improved by pressure and this is of paramount importance here. It must be remembered that the manufacturing and regenerating cost of the copper solution makes it desirable to use it in minimum quantities.

Carbon-Monoxide Removal at Sheffield

The original plan at Sheffield was to remove most of the carbon monoxide by scrubbing with hot concentrated caustic solution (according to the reaction: $NaOH + CO = NaCOOH$) preliminary to the scrubbing with the cuprous solution. The equipment for hot-caustic scrubbing was necessarily very elaborate. A gas-fired tubular heater was installed for heating the gas before it came in contact with the hot caustic. The hot gas passed on to the "lift line," where, acting as an air-lift pump, it carried hot-caustic solution to the top of the scrubber down which the gas and caustic passed over cast-iron packing. The scrubber tower was kept hot by a hot-air jacket supplied by a special gas-fired furnace. The liquid and gas, descending to the bottom of the scrubber, separated in a caustic-solution reservoir; the gas passed out through water-cooled coils for condensing the moisture, which drained back to the caustic reservoir. The solution in the reservoir returned by gravity to the inlet of the lift line to repeat its cycle, but on the way passed through a gas-fired tubular furnace for reheating. For continuous operation partly spent solution was to be drawn from the reservoir, and fresh solution was to feed into the system through still another gas-fired furnace.

Since the hot-caustic scrubbing was finally abandoned it will not be necessary to discuss the principles involved. The intermittent trial runs proved that 75 per cent of the carbon monoxide could be removed by hot caustic. Cuprous-scrubbing is still required for the residual carbon monoxide, and the only net saving by hot caustic is the 75 per cent decrease in the circulation quantity of copper solution. It is doubtful whether hot-caustic scrubbing is economical even if its mechanical difficulties were overcome. The difficulties with the installation at Sheffield finally proved themselves insurmountable and after three months of untiring attempts, hot-caustic scrubbing was abandoned and the carbon monoxide allowed to pass on to the cuprous system for entire removal there. The caustic circulating and lift system, however, remained in service and although a cold solution was used it served to remove residual carbon dioxide, hydrogen sulphide, etc., after the water scrubbers.

Sheffield used cuprous ammonium carbonate instead of the formate for the absorption of carbon monoxide. There seems to be very little difference between the two as to absorptive power for carbon monoxide, but there is considerable advantage in using the formate when stability of the solution is taken into consideration. The carbonate as used at Sheffield gave much trouble in preparation, precipitated metallic copper while in use, broke down considerably on regeneration, and in general proved unsatisfactory.

Control of Cuprous Scrubbing at Sheffield

The original installation for cuprous scrubbing in Unit No. 1 consisted of one tower 2 ft. in inside diameter and 15 ft. tall. The solution was supplied to the top of the tower by a small piston pump drawing from the storage vats and feeding through a "reducing chamber" filled with metallic copper in order to make sure that all the copper in the solution was in a reduced state. It was soon found that the solution required no reduction in operation, the carbon monoxide in solution acting as a reducing agent on regeneration even after the solution had picked up considerable quantities of oxygen during scrubbing. Further, it was found that one tower afforded insufficient scrubbing and two were used, these being placed one above the other, though not directly superposed and so piped together as to operate as one long tower. (See Fig. 9.) The building and location of equipment did not permit setting up a single long tower. The gas passed upward through the towers and through a separator and catch-pot to entrap suspended liquid. The solution passed down the towers and out at the bottom, the discharge being controlled manually with the aid of sight gages, showing the level of liquid in the bottom of the tower. Automatic float chambers installed at Sheffield for controlling the discharge failed to function properly and no alternative from manual control was possible. In the redesign of the plant, an electrical device has been developed which tests indicate should operate very satisfactorily for the automatic control of the various liquid discharges throughout the process.

The copper solution was discharged directly through a line into the regenerating and storage tanks, where it was heated to 70 deg. C. at atmospheric pressure by steam coils and allowed to cool by radiation; no heat interchanger system was installed. Great care was taken in regeneration to avoid contamination of the solution by oxygen of the air. Heating this solution at atmospheric pressure was very destructive and required continuous readjustment of composition (especially the addition of ammonia).

Effect of Refrigeration

In view of the fact that refrigration of the gas for removal of moisture was to follow the copper system at Sheffield, a beneficial change was made during operation to bring part of the refrigeration into effect together with the copper scrubbing. The gas before entering the copper scrubber passed through coils cooled by refrigerated brine. The copper solution on the way to the pumps was also cooled by brine. Although refrigeration does not greatly increase the absorption capacity of the solution at saturation, it does decidedly decrease the carbon monoxide vapor pressure of the solution when it is but partially saturated. Thus, refrigeration does not materially decrease the quantity of solution to be used, but does improve the purity of the gas at the exit of the copper towers where it is in contact with fresh solution.

The gas at Sheffield entered the copper scrubbers with about 4 per cent of carbon monoxide while the exit showed but a few hundredths of one per cent. The methods of analysis for such small concentrations of carbon monoxide in hydrogen were very unsatisfactory and led to considerable uncertainty in operation. The absorption capacity of the solution as used was about 15 cu.ft. of carbon monoxide per cubic foot and 90 per cent saturation was easily obtained (calculated from the quantities of solution used and the volumes of gas scrubbed). The gas entering the scrubbers sometimes contained as much as 0.1 per cent of oxygen which was completely removed by the copper solution and taken care of by reduction during regeneration.

Additional Purification at Oppau

Following the copper scrubbers there are two caustic scrubbers, one in series for each set of parallel copper scrubbing towers. These two towers with mist traps are in the same row and identical in construction with the copper towers. About 3,500 cu.ft. of 30 deg. Bé. solution is circulated per day through the two scrubbers by means of two vertical duplex pumps with 40 hp. motors. It would seem that the caustic scrubber ordinarily aids little in purification but acts as a safety in the line in case the water scrubbers or copper scrubbers do not function properly. Partially spent caustic solution after release of pressure is handled by centrifugal pumps discharging to the final absorption tower of the nitric acid system.

This completes the purification steps in use at the Oppau plant. No precautions are taken to remove moisture, since, as we shall see, the ammonia synthesis system to which the gas passes directly from the caustic scrubbers utilizes water as the scrubbing medium to remove the ammonia from the gas. No steps are taken for removing the very small percentages of carbon monoxide and ammonia that are retained in the gas after leaving the scrubbers.

Additional Purification at Sheffield

It was necessary to dessicate the gas thoroughly at Sheffield in order to protect the particular type of ammonia catalyst selected for use there. This was accomplished by refrigeration followed by soda lime drying. For the former the gas passed through two sets of coils each submerged in a bath of refrigerated brine circulated by a small pump from an ammonia refrigerating system. In later operation, as previously noted, one of the brine coolers was reconnected to precede the copper system. The brine coolers worked very satisfactorily, the only care necessary being to avoid too low a temperature which might freeze the condensed moisture within the coils. The gas passed from the coolers through separators and then upwards through a tower, 15 ft. high and 2 ft. in inside diameter, filled with coarse soda lime. There were two such towers, one being a spare to be repacked while the other was in use.

A tower filled with a special purification material developed as a specific protection against poisons especially dangerous to the catalyst, followed the soda-lime towers. This completed the purification at Sheffield and the gas passed directly to the circulating system for ammonia synthesis.

The fourth installment of this article, in which the actual ammonia synthesis is described, will be published in a subsequent issue.

Study of Gas From Destructive Distillation of a Mixture of Water-Gas Tar and Coal*

By Ralph L. Brown

Associate Organic Chemist,
Pittsburgh Experiment Station, U. S. Bureau of Mines

THE chemical properties of the unsaturated members of the aliphatic series of hydrocarbons are such as to render them ready starting points or basic materials for the synthesis of hundreds of important organic chemicals. The tremendous quantities of these unsaturated compounds that are produced daily in the various coal-carbonization and oil-refining processes and the fact that at present they have little value other than for fuel render a survey of the identity and extent of occurrence of these compounds important from the viewpoint of economic utilization and conservation of our natural resources. The increased need of liquid fuel and the relatively early exhaustion of petroleum resources will eventually require every utilization of liquid fuel products obtainable directly or indirectly from coal. Accordingly the Bureau of Mines has taken advantage of an opportunity[1] for making an examination of the gaseous unsaturated hydrocarbons found in the gas obtained when a mixture of water-gas tar and coal[2] is distilled in a gas-making retort. The results obtained are set forth briefly in the subsequent paragraphs.

Method of Procedure

The method[3] employed in general was to collect the unsaturated compounds in the form of their dibromide derivatives at the plant and to isolate the individual members of the mixture in the laboratory. During the collection the gas was drawn from the system after the tar and ammonia removal had been effected. It was then led in turn through NaOH solution and over solid NaOH for the removal of H_2S, through a large cartridge of activated gas-mask charcoal to remove oils and vapors, through a meter for rate and volume measurements and finally through a train for the absorption of unsaturated compounds. The train consisted of a series of three bottles containing a layer of bromine covered by a little water. Three such trains were used in parallel and were kept in a bath whose temperature was maintained at approximately 5 deg. C. Full cognizance was taken of the work of Read and Williams,[4] in which it was reported that when ethylene was passed into bromine water, approximately one-half the bromine, and consequently a proportional quantity of the ethylene absorbed, go to form the bromhydrin, while less than the remaining one-half forms ethylene dibromide. It has, however, been found experimentally as indicated by the theory that if the entering gas first comes into contact with the bromine as in bubbling through it, the amount of bromhydrin formed is negligible for the purpose in hand. The possibility of bromhydrin formation may be also avoided by omitting the water from the first bottle containing bromine. Most of the absorption of the unsaturated compounds occurs in the first bottle.

The total volume of gas passed was 40 cu.ft., and the average rate of flow through the apparatus was 7.2 liters per hour. The crude bromides produced and collected were washed with Na_2CO_3 solution and water and dried with $CaCl_2$.

Fractionation

A quantity of these crude bromine derivatives was fractionated under diminished pressure in an atmosphere of nitrogen. The distillation flask was heated by immersion in a liquid temperature bath, and the receiver was immersed in a freezing mixture. There was obtained, from 543 g. of crude material, three portions of the following characteristics:

Portion I—430 g., equivalent to 79 per cent, boiling below 60 deg. at 12 mm.

Portion II—14.5 g., or 2.7 per cent, boiling between 60 deg. at 12 mm. and 125 deg. at 35 mm. The evolution of HBr due to decomposition with consequent rise of pressure was evident and the distillation was stopped.

Portion III—94 g., or 17 per cent, of black tarry residue.

The fractionation of portion I after being thoroughly dried was first begun at atmospheric pressure, but evidences of decomposition appeared and it was continued under diminished pressure. The crude fractions corresponding roughly to the dibromides of ethylene, propylene and combined homologs were then fractionated in order at atmospheric pressure, using an 8-in. column. The final fractions were (*a*) 15 g. of boiling range 79 to 83 deg.; (*b*) 228 g. of boiling range 125 to 135 deg.; (*c*) 96.5 g. of boiling range 135 to 145 deg.; (*d*) 25.0 g. of boiling range 145 to 165 deg.; (*e*) 14.6 g. of boiling range 165 to 180 deg., and (*f*) a solid residue of 10.5 g., the loss of 40.4 g. of substance.

Physical Properties of Fractions

These fractions were then examined as to their physical properties. Fraction *a* boiling between 79 and 83 deg. was found to have at 20 deg. a specific gravity of 0.8858 (pure benzene $D\ 20/4 = 0.8799$), to contain only traces of bromine and to possess the characteristic odor of benzene. This fraction was therefore considered as benzene.

TABLE I

Material	Boiling Point, Deg. C.	Sp. Gr. at 20 Deg. C.	Bromine in Per Cent	Carbon in Per Cent	Hydrogen in Per Cent	Total
Ethylene dibromide....	131	2.178	85.07	12.78	2.16	100.11
Fraction *b*.....	125–135	1.982	81.10	16.70	2.71	100.5
Propylene dibromide...	141.6	1.933	79.17	17.84	2.99	100.0
Fraction *c*.....	135–145	1.942	79.40	17.83	2.89	100.1
Butylene dibromides...	148–166–158	1.79-1.82	74.03	22.24	3.73	100.0
Fraction *d*.....	145–165	1.760	71.77	24.76	3.61	100.14
Amylene dibromides...	170–190	1.60-1.70	69.51	.....	....	.....
Fraction *e*.....	165–180	1.629	63.3	.....	....	.....

The next four fractions—namely, *b*, *c*, *d* and *e*—were examined by determining the specific gravity, analyzing for bromine,[5] carbon and hydrogen. The results of these determinations are given in Table I, in which are placed,

[5]Method of Carius was used.

for purpose of comparison, those same constants for the pure dibromides of ethylene, propylene, butylenes and amylenes.

Discussion of Results

In the case of fraction *b*, a first consideration of the specific gravity and the analyses seemed to indicate that this fraction was badly contaminated with propylene dibromide. However, repeated efforts to eliminate the latter by fractional distillation led to the conclusion that the impurity—material other than ethylene dibromide—must be a compound of lower bromine content and higher carbon and hydrogen content than ethylene dibromide, and yet with a boiling point quite close to that of the latter compound. Assuming the bromine content of this fraction to be present entirely as ethylene dibromide, the improbability of the impurity being a simple hydrocarbon is seen from the total nonconformity of the calculated specific gravity of such a mixture with the measured value of the fraction. A survey of the monobromine derivatives of the aliphatic and aromatic series of hydrocarbons led to the belief that monobrompentane (which has a boiling point 129 deg., D 20/4 = 1.2234, bromine content of 52.9 per cent, carbon content 39.7 per cent and hydrogen content of 7.35 per cent) might be the impurity provided it is formed under the conditions which obtained. Assuming monobrompentane to be the only impurity of consequence, simple algebraic calculations, based on the bromine and carbon content of brompentane and ethylene dibromide on the one hand and the values found by analysis for the fraction *b* on the other, indicated the same relative proportions in which the two compounds could be present. An approximate average of the two values showed 87.5 parts of ethylene dibromide and 12.5 of brompentane, and on that basis the calculated values for the hydrogen content and specific gravity agree with those found for the fraction. The values follow:

	Bromine Per Cent	Carbon Per Cent	Hydrogen Per Cent	D20/4
Calculated	81.05	16.2	2.81	1.984
Found for fraction b	81.10	16.7	2.71	1.982

More positive evidence of the presence and identity of the impurity was sought by causing a quantity of this fraction *b* to react, in one experiment with a zinc-copper couple,[6] and in a second with an Al-Hg "Metallpaar," and[7] the resulting gas and vapor passed through a coil cooled to —10 deg., to remove alcohol and unreacted fraction *b* by condensation, and then through a coil cooled to —70 to —80 and finally into bromine cooled to 5 deg. In a catch bulb on the second coil a small quantity of liquid was obtained to which a little ice water was added and the bulb shaken. An upper layer of oil separated, which, when tested by the Menzies method for determining boiling points of small amounts, boiled from 32 to 35 deg. The ethylene dibromide recovered from the bromine in this experiment was found to be practically pure. Further work on the identification of the impurity under question being impossible through a lack of more of fraction *b*, the latter was considered to be 87.5 per cent of ethylene dibromide and about 12.5 per cent of material which the evidence seems to indicate to be a bromine derivative of pentane.[8]

[7] Wislicenus, *J. prakt. chem.*, vol. 54, p. 52 (1896).
[8] The constants and properties of $CH_3CH_2CH_2CBr:CH_2$ would permit it to be considered here in the same proportion. However, the agreement between the calculated specific gravity for such a mixture (1.942) and that found (1.982) is not so close.

In fraction *c*, in view of the conformity of its specific gravity, boiling range and composition with that of propylene dibromide, the fraction was considered to consist practically entirely of that compound.

In fraction *d* it is seen that other material than butylene dibromide (of which there are three isomers theoretically possible) must be present. As in fraction *b*, saturated hydrocarbons may be eliminated and among the monobromine derivatives that might be possible impurities, monobrombenzene and monobromhexane are the most likely. Calculations based on carbon and bromine content showed that approximately ten parts of either compound with 90 parts of butylene dibromide would give a mixture with properties similar to those of fraction *d*. On the other hand, a consideration of the specific gravity of the same two mixtures demands that the greater part of this impurity be monobrombenzene to have the same specific gravity as measured for fraction *d* (calculated 1.764, measured 1.760). In view of the fact that paradibrombenzene was isolated and identified in *e* and in portion II and that fraction *d* amounted to only 25 g. in all, it was considered that fraction *d* consisted of butylene dibromides containing 10 per cent of monobrombenzene.

TABLE II—HYDROCARBONS COLLECTED AS BROMIDE DERIVATIVES (469.5 g.)

		Grams
I.	Benzene	15.0
	Ethylene dibromide	200.0
	Monobrompentane	28.0
	Propylene dibromide	96.5
	Butylene dibromides	22.5
	Monobrombenzene	2.5
	Amylene dibromides	14.5
	Paradibrombenzene	3.0
II.	Paradibrombenzene	3.0
	Liquid dibrombenzenes	12.0
III.	Tetrabrombutane	25.5
	Liquid residue	62.0
	Carbon	6.5
	Total working loss	52.0

In view of the divergence of the constants of the isomeric amylene dibromides and the small total amount of fraction *e*, the latter was taken as an approximate measure of the amylenes and any further unsaturated compounds in the gas.

At the close of the fractionation in vacuo of portion I, there formed, as a sublimate of the residue *f*, monoclinic tablets perfect in form, entirely colorless, melting without recrystallization at 87 deg. From the final combined residue of portion I, paradibrombenzene was obtained and identified by its melting point (88 to 89 deg.) and its bromine content. Three grams was isolated by crystallization at low temperature.

From portion II, obtained in the first distillation, approximately 3 g. more of dibrombenzene was separated by crystallization. The residual mother liquor, 7.6 g., showed on analysis a bromine content of 69.99 per cent, whereas for dibrombenzene the theory demands 67.74 per cent. The specific gravity at 20 deg. was 1.954 and that for ortho- and meta-dibrombenzene is 1.977 and 1.965 respectively (at 18 deg.). This mother liquor was considered to be largely a mixture of dibrombenzene and no further attempts at isolation and identification of the constituents were made.

The residue (portion III) from the original distillation, as previously stated, was a black pitchy mass. The ethereal extract separated a dark liquid amounting to 87.5 g., which, on being well cooled, yielded 25.5 g. of tetrabrombutane (1, 2, 3, 4 derivative) which was identified by its melting point (115 to 116 deg.) and its bromine content. (Theory demands 85.53 per cent;

found, (*a*) 84.43 per cent, (*b*) 85.08 per cent.) The crystals were orthorhombic. No further products were isolated from the 62 g. of mother liquor. The ether extraction residue from III was 6.5 g. of carbon particles of less than micron size and resembling carbon black. They were a product of decomposition during distillation. The presence of the 1, 2, 3, 4 tetrabrombutane undoubtedly indicates the presence of 1–3 butadiene in the gas.

Thus the gas under examination contained in addition to condensable oils largely collected by the charcoal and those gases unaffected by the bromine (CO_2, 1.6 per cent; O_2, 0.5 per cent; CO, 5.3 per cent; H_2, 35.5 per cent; CH_4, 42.5 per cent; N_2, 6.6 per cent) the constituents—forming about 6 per cent of the total gas volume—which are grouped together in Table II in the form and quantity in which they were isolated.

The amounts of the unsaturated hydrocarbons in the gas calculated from the values just given are presented in Table III. In view of the present-day interest in one

TABLE III.

utilization of olefine hydrocarbons from commercial-scale sources of production—namely, the production of their corresponding alcohols—the theoretical equivalents of the unsaturated hydrocarbons are included.

Summary

(1) The unsaturated hydrocarbons of the gas produced by distilling a water-gas tar and coal mixture in a gas retort were collected for study by removing them as their dibromide derivatives.

(2) The identity and approximate amounts of these unsaturated hydrocarbons have been determined.

(3) Most of the compounds contaminating the dibromides of these hydrocarbons have been identified.

Nitrogen in Oxyacetylene Welds

Analyses for nitrogen in oxyacetylene weld metal have been made by the Bureau of Standards on samples which are representative of two types of fracture—crystalline and fibrous. On the basis of combined nitrogen, there seems to be no distinction between the crystalline and fibrous weld metal. The limits of combined nitrogen found were approximately one-sixth the limiting values for nitrogen in electric arc deposited metal—that is, 0.015 to 0.027 per cent nitrogen in oxyacetylene welds, as compared with 0.10 to 0.15 per cent in the arc weld.

Graphic Record of Sulphuric-Acid Plant Operation

By E. B. Rupard

AT THE end of the fiscal year or other operating period it is customary to represent the efficiency of a sulphuric-acid plant by the average niter consumption, chamber space, production and other composite figures of the year's run. Although the actual efficiency is indicated, the figures cannot give an idea of the details of plant operation. If those interested in knowing how the yearly averages were obtained wish to follow the plant operation through the year, the daily, or at least weekly, plant records must be reviewed. This would be a tedious task and probably the conclusions would be vague because the average mind is unable to visualize operations from such a mass of data.

By plotting the plant's record from week to week the detailed results for the year are shown at a glance and a very accurate idea is gained of the manner in which the plant was handled. All variations from normal, as well as efficient running, are shown. If the plant is well managed, the niter and yield curves will show even trends, and on the other hand faulty operation will naturally cause wide variation with consequent poor results.

The acid maker should keep a daily record of any conditions at the plant that would affect the results, such as weather, mechanical trouble, change in methods or apparatus, etc., in order to assist in interpreting any variation from normal. If no outside cause is apparent, most likely the fault is with the management. Likewise where consistently efficient running is shown, it may be profitable to refer to the daily log to ascertain the favorable conditions at that time and if possible attempt to reproduce and maintain them. In this way the graph used with the daily record as reference may serve as a guide in operating the plant as well as a descriptive report on results.

Fig. 1 represents a year's run at a plant that evidently was efficiently managed at all times. During the first week after the plant was started, the niter consumption and chamber space were high, but the operation in the next few weeks showed a decided improvement and the plant was soon running smoothly and efficiently. No radical variations in yields or niter are shown and the chamber space was so adjusted to conditions that the maximum production was realized and an economical conversion and niter consumption maintained.

Fig. 2 covers the second year's run at the same plant with practically identical conditions, although evidently not as carefully managed as in the previous year. From January to July the plant exhibited remarkable efficiency, indicating what might be expected with proper conditions and care. The period between September and January showed wide niter variations and the low yields are most likely due to the lack of uniform operation. From June through August is a period of weekly niter variations; the plant was running on comparatively easy and uniform charges and outside conditions were favorable.

Basing judgment solely on the yearly averages of the two runs, the second year seems very nearly as good as the first. Analysis and study of the graphs, however, show that although the plant had the disadvantage of starting up, the first year was really a great deal better than the second. During the second

Fig. 3—Daily operating record for sulphuric-acid plant Oct. 1 to Nov. 25.

year 3.75 tons more of niter was used, manufacturing costs were $0.023 per ton higher (on the same labor rate), and had the yield of acid per pound of sulphur been 4.89, as in the first year, the production of 50 deg. acid the second year would have been 230 tons.

These items would alone amount to considerable, but the greatest saving the first year had over the second was the better use of the chamber space, producing 2,532 tons more of 50 deg. acid than the second year with only the additional cost of 474 tons of sulphur. The graph indicates how advantage was taken of conditions to utilize the chamber space for a greater production.

Fig. 3 is a daily graphic report of operations which may serve as a guide to the acid maker in detecting errors of management and avoiding their repetition by establishing conditions conducive to good running.

In this graph it will be noted that between Oct. 25 and Nov. 7 niter consumption showed the greatest daily variation. Probably in the operator's anxiety for low niter consumption he reduced the supply too much one day and had to "pot" excessively the next. A mean would have been more economical and better results would naturally have been obtained with a consistent, sufficient supply of niter. This condition was evidently found to be the trouble, as a mean seems to have been established and for the following weeks results were uniform.

The daily graphic record would likely call attention to faulty operation of this kind.

Automatic Load Regulator for Motor-Driven Pulp Grinders

By W. H. Artz
Manager Paper Mill Section,
Westinghouse Electric & Manufacturing Co.

IT IS a well-known fact that the load on motor-driven pulp grinders is very fluctuating, unless regulated. The percentage of load variation is greatest where each grinder is driven by an individual motor and usually least where four or more grinders are driven from a single motor, references in these cases being made to the usual type of three- or four-pocket grinders.

Where the magazine type of grinder is used, having only two pockets per stone, the percentage load variation of a single grinder with individual motor is even more severe than in the preceding cases. Even with two magazine grinders driven by a single motor, the load variations, when pockets are put on or taken off, are such as to cause very unsatisfactory operation if an automatic load regulator is not used.

With the best of care and the greatest degree of supervision of the operation of grinders and the filling of the pockets, it is impossible to maintain anything like a uniform load on the grinders. With the class of labor usually employed the load fluctuations generally vary from 25 to 50 per cent above and below the average load, and it is not uncommon to find, where power is being purchased on a peak load basis, that from 25 to 40 per cent more power is being paid for than is actually being used—i.e., power is being paid for on the basis of a peak perhaps 25 to 40 per cent higher than a curve representing the average load. It was largely to correct this condition and to effect other economies that the Westinghouse automatic load regulator for motor-driven pulp grinders was developed. An installation of this regulator is shown in Fig. 1.

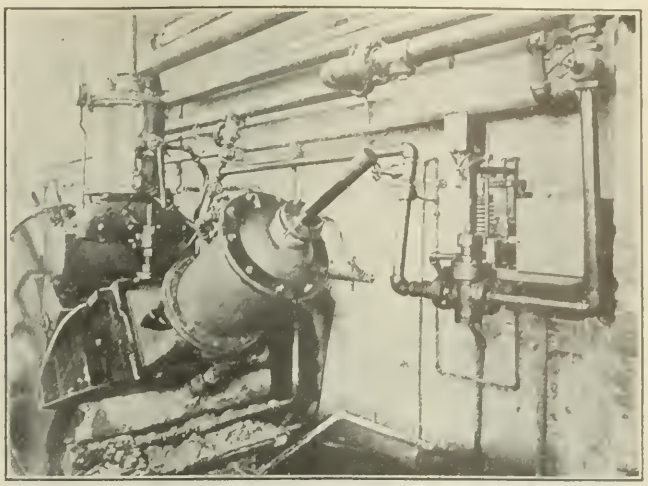

FIG. 1—LOAD REGULATOR ON THREE-POCKET MOTOR-DRIVEN PULP GRINDER AT DEFIANCE PAPER CO., NIAGARA FALLS, N. Y.

With the use of this regulator in connection with each grinder motor, all peaks of any consequence can be prevented, and if ordinary diligence is exercised in keeping the pockets filled, every valley in the load curve, shown in Fig. 2A, can be avoided, thus making practically a uniform straight load curve as the meter chart proves in Fig. 2B, representing constant horsepower input to the grinder motor. This can be accomplished automatically in spite of voltage variations that may take place on the power circuit or change in the power factor setting of the motor itself, and even in spite of the fact that several pockets may be opened at the same time. This precludes all possibility of excess loads and peaks, and assures maximum production and the most efficient and economical use of power.

Description of Apparatus

The Westinghouse automatic load regulator equipment consists of a control panel as illustrated in Fig. 3A, carrying relays, switches and rheostat, the necessary resistance and a motor-operated hydraulic element,

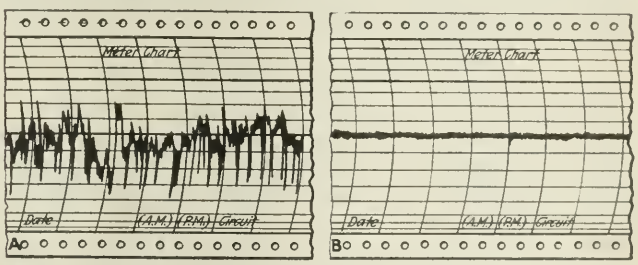

FIG. 2—LOAD CURVE OF PULP GRINDER
A—When not using regulator. *B*—With automatic regulator installed.

shown in Fig. 3B, controlling the water pressure in the pocket cylinders of the grinders being regulated.

The control panel has mounted on it a contact-making watt relay having both current and potential coils; a set of magnetic reversing switches for controlling the direction of rotation of the regulator motor; and a hand rheostat with necessary resistance for determining the load which the grinder motor is to carry.

Two current transformers are used in the grinder motor circuit, the secondaries of the former connecting to the contact-making watt relay. In places where 220-v. alternating current is not available, two small single-phase transformers are provided to furnish poly-

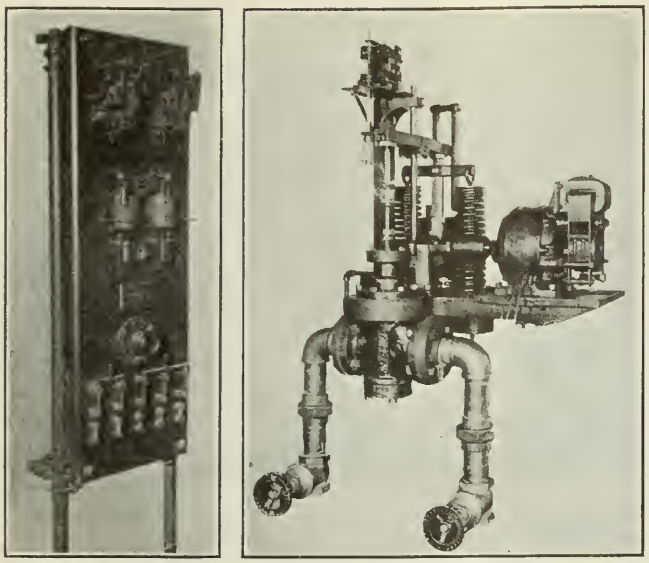

FIG. 3—AUTOMATIC LOAD REGULATOR
A (at left)—Control panel. *B* (at right)—Hydraulic element.

phase current for the regulator motor and for the potential coils of the contact-making watt relay.

The hydraulic element consists of a heavy cylinder type, balanced valve *B* (see Fig. 4) with bleeder element *D*, a small a.c. reversing induction motor *A* with magnetic brake, a moving lever system *L*, a reaction cylinder *M* and a cutout switch *C*. The valve, gears, motor and reaction cylinder are all rigidly mounted in compact form on a common bedplate. The balanced valve *B* controls the hydraulic pressure in the pocket cylinders. Connected directly to the stem of valve *B* is the piston of the bleeder element *D*. The small motor *A* actuated by the watt element raises or lowers the moving lever system *L*, to which is attached the stem of the balanced valve *B*, the piston of the reaction cylinder *M* being attached to the other end of the moving lever *L*. The reaction cylinder *M* is connected to the water-pressure line near the pocket cylinders. The cutout switch *C* limits the travel of the valve and completes the hydraulic element.

Description of Operation

The action of the regulator is as follows:

The sensitive beam of the contact-making watt relay is balanced between two contact points when the grinder motor is carrying the correct load. In case of any decrease in load, such as a pocket taken off for refilling, a change in magnetic pull is exerted on the watt relay and a contact is made, energizing the coil of one of the reversing switches. Thereupon the latter is closed, causing the small motor *A* to rotate in such a direction as to screw upward, through the medium of bevel gears, the vertical rod attached to the lever *L*. The lever *L* fulcrums at the point where it connects with the stem of the reaction cylinder *M*, and the upward movement at the opposite end of the lever increases the opening in the valve *B* and thereby greater water pressure increases the load on the grinder motor to normal or full field. This movement of the small motor *A* takes place very quickly—in fact, in a small fraction of a second—and by it the increase in pressure in the grinding cylinders corrects the load before an appreciable load decrease has occurred.

To prevent hunting, the reaction cylinder *M* is provided. Without the reaction cylinder, the small motor *A* operating through the lever system *L* would open the valve *B* too wide and overload the grinder motor before the watt element would act to stop the small motor *A* or reverse it. The piston in the reaction cylinder *M*, feeling at once the increase in pressure when the valve *B* is being opened, moves upward, which causes the opposite end of the lever *L* connected to the steam of valve *B* to move downward. Counteracting in a measure the movement of motor *A*, as above explained, produces the same effect as stopping the motor *A* before it has overtraveled and permits the lever *L* to assume gradually a position giving a valve opening which keeps the load constant on the grinder motor.

In case of an increase in load, such as a refilled pocket being returned to service, the operations of the regulator are similar to those described above, but in the reverse direction. The watt relay causes the small motor *A* through the lever system *L* to decrease the opening in the valve *B* and reduce the pressure on the pocket cylinders. After the above operation, the tendency is for the stored energy in the hydraulic system to keep the pressure on the pocket cylinders for a considerable time and consequently overload the pulp grinder motor until this pressure is reduced. This condition is overcome by the bleeder valve *D*, which is in the water line between the main valve *B* and the pocket cylinders. When the opening is decreased in the main valve *B*, the bleeder valve *D* opens a greater or lesser

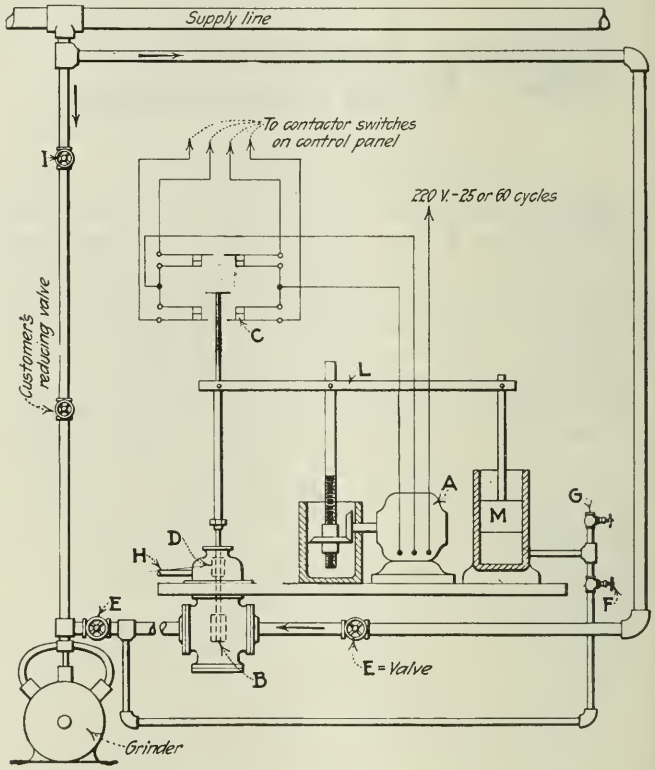

FIG. 4—SCHEMATIC LAYOUT OF HYDRAULIC ELEMENT

degree and relieves the stored pressure at once, thereby eliminating the tendency to overload the grinder motor. Then a further combined action of small motor *A* and the piston in the reaction cylinder *M* restores the valve *B* to the correct position indicated by the load on the grinder motor. A cut-out switch *C* is provided to stop automatically the motor *A* when the travel of the valve *B* has reached its mechanical limit in either direc-

tion—that is, when the valve *B* is wide open or entirely closed.

Advantages

The possibilities and advantages of the automatic load regulator, proved by actual pulp mill continuous operation, may be summarized as follows:

Constant uniform load can be maintained at all times, preventing all peaks and assuring that no more power will have to be paid for than is actually needed.

There will be no valleys in the load curve and maximum production will be obtained, the load being held at a constant uniform value, even though the operator does not keep the pockets filled as he should.

Greater production can be obtained from the motor and grinding equipment than would be possible under any other conditions, on account of the ability to operate the equipment continuously at maximum capacity, without danger of overloading or exceeding the permissible power demand.

The load on the motor can readily be temporarily reduced by turning the hand rheostat, in cases where the power supply is sometimes limited. Such load setting will be automatically maintained until a further change is made.

The regulator prevents the possibility of overloading the motor, which would trip the circuit breaker, shut down the equipment and interrupt production.

The life of the grinder equipment is prolonged by eliminating, by virtue of constant load conditions, the severe strains and wear and tear to every installation having no regulator.

It being a watt regulator—i.e., regulating for constant load rather than for constant current—constant load is maintained without appreciable variation, regardless of line voltage fluctuations or the power factor of the motor. This is of great value as every change in voltage or power factor would affect the load carried by the motor if the regulator were designed to regulate for constant current instead of constant load.

It being of the relay type rather than of the torque motor type, the valve operating motor has ample power under all conditions to give positive action, regardless of friction or foreign matter in the water.

The anti-hunting means, provided on both the electrical and hydraulic elements, give close regulation to any installation consisting of a motor and any number of grinders. It is worthy of note that good regulation can be obtained with a one-grinder equipment which is impossible with other types of regulators, due to the large load change when one of the pockets is cut out of service for refilling or repairs.

New Chemical Companies Organized

During the month of January, 32 new companies were organized with capital of $50,000 or more, to manufacture chemicals, chemical byproducts, drugs, etc., with aggregate capitalization of $37,650,000. This is a large increase over December, when 26 companies were incorporated, with a capital of $3,595,000, and also a decided advance as compared with January, 1921, which registered indicated capital of new companies of $22,295,000.

In the same month 92 new oil and petroleum companies were formed with individual capital of $50,000 and over, with aggregate capitalization of $100,250,000. This is considerably higher than the record for December, 1921, which showed 58 such new companies organized, with total indicated capital of $65,615,000.

Synopsis of Recent Chemical & Metallurgical Literature

Chromium-Molybdenum Steel.—C. N. Dawe, metallurgical engineer for the Studebaker Corporation, presented a paper on "Chromium-Molybdenum Steel Applications From the Consumer's Viewpoint" before the recent meeting of the Society of Automotive Engineers, in which he presented the results of 400 tests made in the laboratory of a large consumer of alloy steels. Over 2,000 tons of molybdenum steels of various analyses have been put through production in the form of rear-axle shafts, transmission gears and shafts, steering knuckles, steering-knuckle pins, ring gears and drive pinions—in fact, all parts for which alloy steel is specified. By a process of elimination it became clear that an analysis showing a carbon content below 0.30 and above 0.23 per cent, with a chromium content of 0.70 to 0.90 per cent and molybdenum 0.30 to 0.40 per cent, gives satisfactory results with water as a quenching medium, there being no cause for concern pertaining to the development of quenching cracks.

"The wide heat-treating range of a given steel is a property upon which great stress always seems to be laid, but in this present day of accurate metallurgical control we do not need a 100 to 200 deg. quenching range. What we as consumers are mostly interested in is to determine the lowest quenching temperature that can be used commercially and still obtain the maximum physical properties. With this in mind, three quenching temperatures ranging from 1,550 to 1,650 deg. F. were used in the case of the chromium-molydenum, chromium-vanadium and chromium steels, while 1,475 to 1,575 deg. F. were used with the chromium-nickel steel used for comparison purposes. Three drawing temperatures (1,000, 1,100 and 1,200 deg. F.) were used for each quenching temperature."

Physical properties obtained, true to expectations, were occasionally variable in all four types of steel, and his published results are therefore the results of very broad averages.

"Generally speaking, in performing tests of the above nature where we desire to note a comparison of the physical properties of certain steels in terms of the elastic limit, ultimate strength, reduction of area and percentage of elongation, sometimes we are confused because of the variations we obtain, and because it is practically impossible, over a large number of test-pieces, to hold any one or two factors constant so as to note the variation in the remaining factors. If we could heat-treat the test-pieces so that the elastic limit would be the same in all, the variation in the three other remaining factors would tell the story." Failing in this, a comparison by merit index[1] was made, which gave a higher figure for chromium-molybdenum steels than for its competitors. In view of the fact that this steel apparently can be produced in unlimited quantities with no danger of shortage of molybdenum, and because it has been produced and sold at a lower price than its closest competitor, chromium-vanadium steel, its adoption has been sanctioned. It forges entirely satisfactorily, with the particular advantage that the scale formed breaks away from the forgings very easily. With proper composition and for sizes within ordinary limits, it cold-shears as readily as the other grades of commercial alloy steels. It responds very readily to the heat-treating operations, the percentage of forgings falling outside of the required Brinell hardness being very small.

"With reference to its machine qualities, no figures can be given. However, we have satisfied ourselves by noting the machinability of the tonnage that has passed through our shops that chromium-molybdenum steel machines at least as well as the best there is. We have not heard of a

[1] $Merit\ Index = \frac{Elongation\ (Elastic\ Limit + Ultimate\ Strength)}{2{,}000\ (100 - Reduction\ in\ Area)}$

failure of any part made of this steel out of the 50,000 cars that have thus far been produced since its adoption."

Since the Studebaker Corporation is a very large user of carbonized parts, and published literature on molybdenum steels contained little such data, a heat of steel containing 0.13 C, 0.40 Mn, 0.61 Cr and 0.35 Mo was case-hardened. This analysis was abandoned for the reason that too high temperatures were required for double heat-treatment. Quenching directly from the carbonizing box and using a single lower heat for hardening did not produce the desired core fracture. Preliminary work on another analysis (0.19 C, 0.54 Mn, 0.70 Cr and 0.37 Mo) was very encouraging, and transmission parts for 5,000 cars were ordered. It was often noted that a test fracture under shock would not show a "tough core," but would have a crystalline or granular appearance, particularly objectionable in parts that are subjected to a straightening operation and in clash gears. In order to obtain better results, the part to be heat-treated had to be subjected to prolonged heating above the critical temperature of the core to bring about the proper condition before quenching and the lower heat for hardening had to be applied as quickly as possible to prevent the core from being subjected to lengthy heating at the lower temperature.

To obtain the best possible results with the case-hardened parts it was necessary, therefore, to quench from the carbonizing box into oil and follow this by the regular double heat-treatment and a final draw at 375 to 400 deg. F., timing each operation as carefully as possible. There are two particular advantages that should be noted, however, in that chromium-molybdenum steel will take on a given case-depth in 10 per cent less time than chromium-nickel steel; also, there will be a resultant average increase of 5 to 7 points scleroscopic hardness.

"Chromium-nickel steel apparently still holds the first place among commercial steels for case-hardening of important parts, but nickel-molybdenum steel (0.13 C, 0.38 Mn, 1.58 Ni, 0.20 Mo) will be a serious contender, principally because of its ability to harden in oil after carbonizing a rolled (not forged) piece. For instance, steering knuckles have always before been water-hardened, necessitating some rejections due to subsequent straightening. However, of one lot of 1,949 nickel-molybdenum pins carbonized and hardened in oil, not one was lost in straightening or because of softness after final grinding."

The Technical Hydrogenation of Hydrocarbon, Nitrobenzene and Coal.—The *Journal of the Society of Chemical Industry* (vol. 40, No. 23, p. 445R, of Dec. 15, 1921) contained an interesting article on the technical hydrogenation of hydrocarbon, nitrobenzene and coal. It leads to the conclusion that the field of hydrogenation has thus far been but little more than scratched and offers at the same time an engaging prospect for research.

The production of cyclohexane from benzene is not of leading technological importance, although the hydrocarbon has been used in the production of synthetic rubber. Naphthalene when purified has been successfully hydrogenated in Germany to tetrahydronaphthalene, and called "Tetralin" by the Gesellschaft mit beschränkter Haftung of that name at Rodleben, near Rosslau. They produce 120 tons daily. They make also decahydronaphthalene by permitting the absorption of hydrogen to continue further, and a mixture of the tetra and deca products is known on the market as "Tetralin Extra." The deca product, being a fully saturated hydrocarbon, is unattacked by sulphuric or sulphurous acid, and may be likened to paraffin hydrocarbons. The "tetralin," on the other hand, has one benzene nucleus not hydrogenated and suggests many derivatives for use in making dyes and fine chemicals. Besides the war-time use of tetralin as a substitute for turpentine its use is indicated as a motor fuel, as an illuminating oil, as an insecticide, as a solvent for rubber, hydrocarbons, fats, dyes, etherial oils, etc., and as a starting point for dyes.

It is proposed to undertake the hydrogenation of cracked petroleum oils, and thus to avoid important losses. Nitrobenzene is reduced under a Badische patent in which a mixture of CO and steam or water gas and steam react with a copper catalyst to produce aniline. Other methods have been proposed in addition, but an interesting feature of the former is the use of copper as originally proposed by Sabatier in the place of nickel, which would certainly produce cyclohexamine. Copper, on the other hand, is unable to induce hydrogenation of the benzene ring, although it readily acts in the reduction of the nitro group. The Badische process may in time replace the standard method of reducing nitrobenzene with iron borings.

The hydrogenation of alkaloids is another field of peculiar interest, in that it has been observed that in certain cases the toxicity of the original alkaloid is materially diminished by the process.

Of immense interest is the hydrogenation of coal, and here it appears that the Germans have made considerable advance, although they do not seem to have reached any striking success as yet. In the Bergius patent (Br. Pat. 4,574, 1914) it is stated that coal is treated in autoclaves at 400 deg. C. and under high pressure of hydrogen. (Berthollet obtained an artificial petroleum by the action of hydriodic acid on coal in sealed tubes.) Fischer and Schrader, in *Brennstoff Chemie* (1921, vol. 2, p. 161) describe the liquefaction of coal by means of sodium formate. Rhenish lignite yields 7 per cent of tar by destructive distillation, but if mixed with four times its weight of sodium formate the yield is 23 to 27 per cent, and greater if the pressure of gaseous decomposition and steam is kept constant. Thus 45 per cent of tar was obtained from a mixture of one part lignite and two parts sodium formate and 48 per cent from a mixture of one part fuel and eight parts of the salt. The increased production is attributed to the influence of nascent hydrogen from the decomposition of the sodium formate. Molecular hydrogen is said to have very little effect. Fischer and Schrader further say (*Brennstoff Chemie*, 1921, vol. 2, p. 257) that the presence of carbon monoxide at increased temperature such as 500 deg. C. and under pressure gives better yields than hydrogen as in the Bergius process, but that it is less successful than when sodium formate is employed.

Recent Chemical & Metallurgical Patents

American Patents

Complete specifications of any United States patent may be obtained by remitting 10c. to the Commissioner of Patents, Washington, D. C.

Production of Ferrozirconium.—Ralph H. McKee, of New York City, patents a method for making ferrozirconium, substantially free of Al, not more than 3 per cent Si and containing 20 to 40 per cent Zr, and 0.5 per cent C, by fusing a mixture of 500 parts granular zircon with 300 parts cast iron, 250 parts CaO and 25 parts fluorspar in a resistance furnace. (1,401,265. Dec. 27, 1921.)

Zirconium Steel.—Ralph H. McKee, of New York City, claims to be able to make zirconium steels by merely adding zirconium oxide or silicate minerals to the molten iron or steel, without fluxes or other reagents. About one-quarter of the metal in the added mineral is reduced and enters the alloy; in this way irons containing as high as 20 per cent Zr may be made. (1,401,266 and 1,401,267. Dec. 27, 1921.)

Heat-Treatment of Aluminum Alloys.—Earl Blough, of Parnasus, Pa., finds that a great variety of Al:Cu alloys may have their tensile strength greatly increased by a proper double heat-treatment, combining a thorough anneal at about 520 deg. C. and a quench in boiling water, in which it is permitted to remain for several hours. The high temperature should be maintained for a sufficient time to relieve strains, allow recrystallization and uniform diffusion of soluble constituents. Accelerated aging of the quenched specimen is effected by the bath of boiling water. (1,394,534; assigned to Aluminum Co. of America. Oct. 25, 1921.)

Recovery of Chromium From Iron Ore.—F. A. Eustis of Milton, Mass., proposes to leach finely divided soft Cuban iron ores with weak HCl with or without H_2SO_4, extracting

therefrom Fe, Al, Ni and Mn, and leaving behind SiO_2 and the chromium minerals in such enriched form that the latter can be easily recovered by smelting, (1,403,237; partially assigned to C. P. Perin. Jan. 10, 1922.).

Molybdenum From Molybenite.—G. W. Sargent and J. W. Weitzenkorn, of Washington, Pa., have discovered an exothermic reaction between molybdenite and manganese oxide:

$$MoS_2 + 2MnO_2 + 4C = Mo + 2MnS + 4CO$$

The powdered reagents (with or without iron filings) are mixed, heated to 2,000 deg. F., whereupon a button of substantially pure Mo (or ferromolybdenum) forms, containing less than 0.10 per cent sulphur, overlain by a clean, fluid slag. If carbon is not added to the mix, the end product is a reducible Mn:Mo:S compound. Or the complete reaction may be effected during steel-making operations, with the resultant formation of excellent alloy steel. (1,401,924. Dec. 27, 1921.)

Primary Detonating Compound.—This invention refers to the use of diazodinitrophenol (4.6-dinitro-2-diazophenol) as a substitute for the fulminates, azides, etc., used in primary detonating charges. Non-metallic primers have met with little use for reasons of high cost, low brisance, unfavorable temperatures of melting and ignition and undependable sensitiveness to shock. It is claimed that diazodinitrophenol is free from these objections and can be used for general primary detonating charges and for special charges designed to avoid fouling and amalgamating the metals of ordnance. It is not hygroscopic and is stable in the presence of acids, hence is not decomposed by decomposition products of explosives during storage. When mixed with potassuim chlorate it is claimed to reveal greater power than the most efficient mixtures of potassium chlorate and mercury fulminate. (1,404,687. W. H. Dehn, Seattle. Jan. 24, 1922.)

Book Reviews

A LIFE OF GEORGE WESTINGHOUSE. By *Henry G. Prout, C.E., A.M., LL.D.* New York: Charles Scribner's Sons. 1922. Price, $2.50.

This is an interesting book about a remarkable man who was one of the great American inventors. The name Westinghouse, now known all over the world, appears to have been originally Wistinghausen until on the immigration of the pioneer to New Hampshire in 1755, when it was changed to the present style. Genealogy is seldom illuminating, because many of the factors are illusive, but the Westinghouse strain seems to have held true to form. There was the original John of 1755 who came over with his widowed mother when he was fifteen years old. On the ship he made for his mother an inlaid wooden work-box which is still in existence. John cleared the land, built a log cabin and raised a large family. That inlaid work-box indicates a mechanical knack. John was 6 ft. 4 in. tall. One of his sons was John Ferdinand, who had twelve children, the fifth of whom was George, Sr. He settled in Central Bridge, N. Y., married Emmeline Vedder, a cousin of the famous artist, Elihu Vedder, whose illustrations of the Rubaiyat of Omar Khayyam will be familiar to most of our readers. They had ten children, of whom George, Jr., was the eighth. George, Jr., was born in 1846. Ten years later George, Sr., established himself at Schenectady as G. Westinghouse & Co., makers of agricultural and mill machinery and small steam engines, on the site of the entrance to the General Electric Co.'s present great works.

There were three sons of the Schenectady master mechanic who served in the civil war: John, Albert and George, Jr. The tradition is that Albert, who was singularly gifted in mind and character, was the most promising of all the sons. He was killed while leading a cavalry charge in 1864. John served as an engineer officer in the navy and then returned to his father's business in Schenectady. There he established a night school and a mission, and he gave all his available time to helping the unfortunate. He died when George was forty-four years old.

If we were considering a baseball hero or a race horse we should be very diligent in noting qualities of inheritance, but we are less addicted to this in considering men who achieve greatness. We present the data, together with a reminder of his younger brother, Henry Herman Westinghouse, of Pittsburgh, and the fact that a considerable number of the Wistinghausen family in Westphalia have received patents of nobility, to indicate the strong rather than a weak biological strain that was the inheritance of George Westinghouse, Jr.

When George returned from the war, having enlisted at sixteen and been mustered out under nineteen, he entered Union College as a sophomore, but 3 months later he returned to the shop. The old "Hands Book" of the shop also shows that back in 1860 when he was thirteen and one-half years old he worked there for 50 cents a day, and that in 1863 he was getting $1.12½ a day. It appears therefore that after George was thirteen years old he had but 1½ years of school and college. Nevertheless he wrote and spoke English uncommonly well.

His first patent invention was a rotary steam engine, recorded in 1865. The foundation of his fame and fortune was the air brake, on which his first patent was granted in 1869. By 1873, when he had moved to Pittsburgh, he had taken out twenty or more patents on details of brake apparatus. Then followed at various times friction draft gear and the immense electric activities in which Westinghouse had the vision and the energy to press the development and application of alternating currents. This was a herculean task that we can only mention. In like manner we can only mention the development of the induction motor and meter, the rotary converter, turbo-generators, signaling and interlocking, and a vast number of other activitities.

His most outstanding quality today is the fact that while he was not scientifically trained (and all his life he felt his defect in higher mathematics and physics) he had the scientific spirit. He gathered men of sound scientific training about him and worked with them. He was on terms of intimate friendship with the leading scientific minds of the world. Unlike some chemical manufacturers of today, he respected science, revered it, had it in his blood, recognized its intricacies and did not suffer from the illusion that he could carry it on his pocket-book.

He blazed the trail for the introduction of science into industry. It would be gratuitous to say that he was alone in this, but the number of these pioneers is small. Look at the number of great engineers of today who have been through the course as graduates with the Westinghouse Co. and the General Electric Co.! Can the chemical industry of this country point to such a number of able, courageous and commanding men as the electrical industry has turned out? Everybody knows it cannot. And everybody ought to know why.

He was an idealist all the time and an optimist when others were lost in darkness. The panic of 1907 swamped him, and receivers were appointed for the Electric company. It would be difficult to make a correct analysis of the causes of this. Whether the single-phase electrification of the New Haven Railroad had much to do with it or not would probably be debated. Many lenders ask high discounts when money is scarce, and he may have held off too long. He made many mistakes among his efforts, and without doubt he made them in his financial planning. But when the crash came, he put what he had back in the works and so did his employees. And while he died in moderate circumstances, the works continue to do what he planned for them to do, and the name leads on, unsullied by failure.

ELLWOOD HENDRICK.

CHEMICAL REACTIONS AND THEIR EQUATIONS. A Guide and Reference Book for Students of Chemistry. By *I. W. D. Hackh*, professor of biochemistry, College of Physicians and Surgeons of San Francisco. Philadelphia: P. Blakison's Son & Co. Price, $1.75.

This convenient and helpful book was reviewed in our issue of Dec. 7, 1921. In that review the price was stated to be $1.25 and some readers have sent in orders with only that amount inclosed. The correct price, as stated above, is $1.75.

Outlining the Legitimate Activities of Trade Associations

ONE of the disturbing factors in the present business situation has been the uncertainty regarding the definition and scope of the activities of legitimate trade associations. Ever since the Supreme Court's decision in the case of the Hardwood Manufacturers' Association, business has anxiously awaited the anouncement of the government's attitude toward trade associations. It had been hoped that through the services of Secretary of Commerce Hoover, the Attorney-General might be induced to prepare a formal statement in the nature of an interpretation of the Supreme Court's decision. Following a number of conferences between officials of the Justice and Commerce Departments it was finally decided, however, that the government's statement should take the shape of "an informal interdepartmental inquiry regarding the present status of the law relating to legitimate trade associations and the extent that they may engage in legitimate co-operative activities."

The Hoover Inquiries

In the interdepartmental correspondence, which has recently been made public, Secretary Hoover has outlined a vigorous defense of the legitimate trade association as an essential service to industry. He made the following statement in the first of his letters to the Attorney-General:

> It is with much earnestness that I claim there is propriety, generally speaking, in trade associations. Their lawful field of endeavor is large, and their activities work for promotion and advancement of the public welfare and for progressive economic organization. In making this statement, I am not unmindful of the fact that the impression exists with a small minority that individual prohibited acts may be accomplished by organization under the disguise of a trade association. However, to make my position clear regarding the trade associations the existence of which I advocate, I desire to say that I have always taken the view that no body of men could combine in the form of a trade organization and do any act or thing forbidden by law if they were undertaken by them outside of a trade organization. The character of trade organization the existence of which should be preserved is one that carries only lawful purposes in its articles of association; its activities must be in harmony with its declared purposes. The articles of association, with their lawful, declared purposes, must not be used as a mask to hide unlawful purposes. In other words, the organization cannot be used to conceal or disguise any contract, combination, conspiracy, agreement or understanding, secret or otherwise, on the part of the officers of the organization or on the part of the membership or any part thereof to engage in activities in restraint of trade or otherwise in violation of the anti-trust laws.

The Attorney-General was asked by Secretary Hoover for an informal expression of his views as to the following activities of trade associations and their members, it being assumed, of course, that neither the form of the association nor the activity which appears perfectly fair and lawful on the surface is used to hide or conceal some contract, combination, conspiracy, agreement or understanding, secret or otherwise, on the part of the association, the membership or any part thereof actually to restrain trade or otherwise violate the Sherman act:

Uniform Costs and Industrial Standardization

(1) May a trade association provide for its members a standard or uniform system of cost accounting and recommend its use, provided that the costs so arrived at by the uniform method are not furnished by the members to each other or by the members to the association and by the latter to the individual members?

(2) May a trade association advocate and provide for uniformity in the use of trade phrases and trade names by its respective members for the purpose of ending confusion in trade expressions and for harmony of construction as to the meaning of trade phrases, names and terms?

(3) May a trade association, in co-operation with its members, advocate and provide for the standardization of quality and grades of product of such members, to the end that the buying public may know what it is to receive when a particular grade or quality is specified; and may such association, after standardizing quality and grade, provide standard form of contract for the purpose of correctly designating the standards of quality and grades of product; and may it standardize technical and scientific terms, its processes in production and its machinery; and may the association co-operate with its members in determining means for the elimination of waste processes in production and distribution and for the raising of ethical standards in trade for the prevention of dishonest practices?

Credit, Insurance and Co-operative Advertising

(4) May a trade association collect credit information as to the financial responsibility, business reputation and standing of those using the products of the industry; and may the association furnish such information to individual members upon request therefor, provided such information is not used by the association or the members for the purpose of unlawfully establishing so-called "blacklists"?

(5) May a trade association arrange for the handling of the insurance of its members, including fire, industrial, indemnity or group insurance? In other words, can the members of an industry, through the agency of a trade association, arrange for or place all of the insurance of the members?

(6) May a trade association, in co-operation with its members, engage in co-operative advertising for the promotion of trade of the members of that association engaged in the particular industry; and may the association engage in such form of promotion by furnishing trade labels, designs and trade marks for the use of its individual members?

Industrial Relations, Legislation and Governmental Co-operation

(7) May a trade association, for and in behalf of its members, engage in the promotion of welfare work in the plants or organizations of its members, which welfare work includes sick benefits and unemployment insurance for employees, uniform arrangements for apprenticeship in trade education, the prevention of accident and the establishment of an employment department or bureau for co-operation with employees?

(8) May a trade association, in co-operation with its members and acting for and in behalf of its members, handle all legislative questions that may affect the particular industry, regarding factories, trades, tariff, taxes, transportation, employers' liability and workmen's compensation, as well as the handling of rate litigation and railroad transportation questions?

(9) May a trade association, in co-operation with its members and acting for and in their behalf, undertake the promotion of closer relations between the particular industry and the federal and the state departments of government which may have administration of laws affecting the particular industry in any form?

Statistics of Production, Distribution and Prices

(10) *A.* May a trade association collect statistics from each member showing his volume of production, his capacity to produce, the wages paid, the consumption of his product in domestic or foreign trade, and his distribution thereof, specifying the volume of distribution by districts, together with his stock, wholesale or retail?

B. And may such trade association, on receipt of the individual reports of each member, compile the information in each report into a consolidated statement which shows the total volume of production of the membership, its capacity to produce by districts of production, which, in some instances, include a state or less area, the wages by districts of production, the consumption in foreign or domestic trade by districts, the volume of distribution by districts and the stocks on hand, wholesale and retail, by districts?

C. And if, after compiling the information as aforesaid, the information received from the members as well as the combined information is not given by the association to any other person, may it then file the combined statement with the Secretary of Commerce for distribution by him to the

members of the association through the public press or otherwise and to the public generally and to all persons who may be in any way interested in the product of the industry, it being understood that the individual reports for the members should cover either weekly, monthly, quarterly or longer periods as may be deemed desirable by the members, and, when a period is adopted, the report for each member shall cover that period, and the combined report shall be for that period?

(11) *A.* May a trade association, at the time it collects the production and distribution statistics above outlined, at the same time have its members report the prices they have received for the products they have sold during the period taken, specifying the volume of each grade, brand, size, style or quality, as the case may be, and the price received for the volume so sold in each of the respective districts where the product is sold?

B. And may the association, without making known to any person the individual price reports of any member, consolidate all of the reports into one, and show the average price received for the total volume of each grade, brand, size, style or quality, as the case may be, distributed in each district covered by the distribution statistics for the period covered by each individual report?

C. And may the association, after making such compilation, send the compiled report as to average price, as aforesaid, to the Secretary of Commerce, to be by him distributed to the public and to any or all persons who may be interested in the particular industry making the reports?

The Attorney-General's Reply

Mr. Daugherty's answers to these questions are contained in his letter to the Secretary of Commerce dated Feb. 8, 1922. The Attorney-General laid particular stress on the subjects of uniform cost accounting and standard trade marking and labeling especially when used as a means of restraining trade and competition. His statement is, in part, as follows:

Suspicious of Uniform Costs

With reference to the first paragraph, there is no apparent objection to a standard system of cost accounting, but I think associations should be warned to guard against uniform cost as to any item of expense. For illustration, a strong effort has been made by some lumber associations to take as a basis for estimating costs of production a uniform charge for stumpage. Of course the cost of the timber in the tree to the different manufacturers who own their timber in the woods varies greatly; and as to each it should be charged at its actual cost. It is as clearly a violation of the law to agree upon the cost of an item that constitutes a substantial part of the total cost price, when its cost actually varies, as to agree upon the sales price, because the sales price is substantially affected by such agreement. It has been ascertained that the members of one association go so far as to fix a uniform cost price, leaving to each member to determine what per cent profit he will add, thus eliminating competition entirely in so far as affected by the cost of production.

Uniform Labels Destroy Competition

Furthermore, I have serious doubts about the advisability of the latter part of the sixth paragraph. I can see no objection to co-operative advertising designed to extend the markets of the particular article produced or handled by the members of an association, but when the several producers or dealers use uniform trade labels, designs and trade marks it seems to me the inevitable result would be a uniformity of price. Where two competing articles are advertised in precisely the same way and bear exactly the same label or trade mark, it certainly would be difficult for one to be sold at a higher price than the other, although its quality may be superior. In a way this is illustrated in the cement industry. There a standard of quality has been adopted—that is, it is necessary for all cement to comply with a certain standard—but in practice no manufacturer undertakes to make, or at least no one advertises that he does make, a grade of cement superior to that standard. The result is that there is no competition in the sale of cement so far as quality is concerned. It seems to me therefore that it would be well to eliminate the latter clause in paragraph 6—to wit, "and may the association engage in such form of promotion by furnishing trade labels, designs and trade marks for the use of its individual members?"

I can now see nothing illegal in the exercise of the other activities mentioned, *provided always* that whatever is done is not used as a scheme or device to curtail production or enhance prices, and does not have the effect of suppressing competition. It is impossible to determine in advance just just what the effect of a plan put into actual operation may be This is especially true with reference to trade associations whose members are vitally interested in advancing or, as they term it, stabilizing prices, and who through the medium of the associations are brought into personal contact with each other. Therefore the expression of the view that the things enumerated by you, with the exceptions stated, may be done lawfully is only tentative; and if in the actual practice of any of them it shall develop that competition is suppressed or prices are materially enhanced, this department must treat such a practice as it treats any other one which is violative of the anti-trust act.

Community Trade Slogans and Not Trade Marks

Mr. Hoover in a second communication offers a further explanation of paragraph 6, which had been questioned by the Attorney-General. It was intended that the question should really relate to trade promotion through the use of trade slogans, such as "Made in Grand Rapids," and not to the use of the same trademark by every member of an association. Since this is primarily the sort of co-operative advertising to which Mr. Daugherty referred—i. e., "designed to extend the markets of the particular article produced or handled by the members of an association," it is apparent that the views of the two departments are in complete accord.

A List of Trade Association Activities

The fabricated production department of the U. S. Chamber of Commerce has prepared a tentative list of trade association activities which is based upon returns received from many association secretaries. It will be noted that in addition to those discussed in the Hoover-Daugherty correspondence there are numerous activities which have had the attention of the various trade associations. The listing by the Chamber of Commerce is not, however, an indication of the legal character of the different activities and no effort has been made to comment on their relative importance to business. The list of seventy-eight trade association activities is as follows:

Adjustments.
Advertising.
Arbitration.
"Association Spirit" and "Acquaintanceship."
Bulletins.
Classifications.
Collections.
Compensation.
Compilation of Trade Information.
Conservation.
Co-operation.
Co-operative Advertising.
Co-operative Buying.
Co-operative Selling.
Co-operation With Other Trade Organizations.
Cost Accounting and Cost Finding.
Credit Bureau.
Demonstrations.
"Distribution and New Markets."
Educational.
Eliminations of Excess Variety.
Elimination of Abuses (Trade Practices).
Employment Bureau.
Ethics of Business.
Exchange of Surplus Materials.
Exhibits.
Financial Statement Consolidated, Yearly.
Foreign Trade Service.
Freight Classification.
Group Meetings.
Hand Books.
House Organs.
Industrial Bureau.
Inspection Service.
Insurance.
Investigations. Technical (Testing, etc.).
Labor Problem.
Legal Advice.
Legal Aid.
Legislative Work.
Litigation.
Market Reports.
Materials, Raw.
Methods.
Open Price Bureau.
Open Shop.
Organization.
Patents and Trade Marks.
Price Data Exchange.
Production.
Publicity, General.
Purchasing.
Price Lists and Classified Buyers' Guides.
Relation Between Own Industry and Allied Industries.
Research.
Restriction of Production.
Sales Promotion.
Social Contact of Competitors.
Standardization.
Statistics (1. Production, 2. Shipments, 3. Orders).
Statistics, Production.
Statistics, Wage Rates, Volume of Orders on Hand, Cost of Manufacture, Overhead Expense.
Style Bureau.
Tariff Work.
Taxation.
Technical Education.
Technical Information.
Trade Extension Work.
Trade Information.
Trade Marks and Copyrights.
Trade Practices (Co-ordination).
Trade Promotion (or Stimulation).
Traffic Department.
"Unfair Competition Bureau."
Wage Rates Compilation.
Wage Schedules, Detailed.
Washington Representation.
Welfare.

Technical News of the Week

Current Events in the Chemical, Metallurgical and Allied Industrial Fields—Legislative Developments—Activities of Government Bureaus, Technical Societies and Trade Associations

Chemical Research for Army and Navy Threatened by Abolition of Gas

If the treaty among the United States, Great Britain, France, Italy and Japan dealing with the use of submarines and gases in warfare is ratified, there is reason to believe that an attempt will be made not only to abolish the Chemical Warfare Service as such but to stop practically all of the research work being done on war gases. A good deal of money is being expended at Edgewood Arsenal and in view of the way expenses are being lopped off, it is regarded in Washington as highly probable that executives will not overlook this chance to reduce expenditures.

The Chemical Warfare Service brought to the military and naval establishments the first chemical research of any proportion ever undertaken in these large and important government departments. Every effort has been made at Edgewood Arsenal to be helpful to all branches of the Army and the Navy when a matter of chemistry was involved. Unless a very determined protest is made, the chances favor the wiping out of this service.

It will be recalled that Congress has been more alive to the chemical warfare situation than have the General Staff or secretaries of war. Due to the fact that Congress now has under consideration the War Department appropriation bill, it will have an opportunity to present its own interpretation of the gas treaty. Hearings on this bill are now in progress before the Appropriations Committee of the House. Every effort will be made to convince the committee that gas research should continue as a necessary measure toward national defense with which can be combined such other chemical research as is required by the Army and Navy.

E. F. Smith to Deliver Chandler Foundation Lecture at Columbia University

Friends of Professor Chandler presented in 1910 to the trustees of Columbia University a sum of money which constitutes the Charles Frederick Chandler Foundation. The income from this fund is used to provide a lecture by an eminent chemist and to purchase a medal to be presented to the lecturer in further recognition of his achievements in science. Previous lecturers on this foundation were L. H. Baekeland, Sc.D., W. F. Hillebrand, Ph.D., W. R. Whitney, Ph.D., and F. Gowland Hopkins, Ph.D.

The lecturer this year will be Edgar Fahs Smith, formerly professor of chemistry at the University of Pennsylvania, now president of the American Chemical Society. Dr. Smith's subject will be "Samuel Latham Mitchill—A Father in American Chemistry." Samuel Latham Mitchill was the first professor of chemistry at Columbia College and the first Senator from the State of New York. The lecture will be in Havemeyer Hall, Columbia University, on March 2, 1922, at 8:15 p.m.

Revised Patent Office Relief Bill Passes Senate Without Opposition

Not even the most optimistic friend of the Patent Office relief bill expected that measure to go through the Senate without considerable debate. The greatest surprise of all was that no roll call was demanded. Senator Johnson simply pointed out that the Senate is entirely familiar with this measure, which had been passed at the last session but which failed due to differences in conference over a proposal to handle government employee patents on a preferred basis, which is not a part of the present measure.

The bill provides for an increased salary schedule for technical employees in the Patent Office and authorizes the reorganization of that important bureau.

Discussion Aroused by Superpower Report Paves Way for Further Action

Now that ample time has been given to obtain the reactions of the electrical industry to the superpower report, the members of the advisory board are to be called together in the near future for further discussion of the project.

Dr. George Otis Smith, director of the U. S. Geological Survey, under whose direction the superpower report was prepared, believes that the showing of economies presented in the report has stimulated interconnection between existing systems throughout the country. The nationwide interest that has been taken in the report is indicated by the fact that the entire edition of 10,000 copies of the report has been exhausted. Thousands of inquiries have been received in regard to various phases of the problems involved and a large amount of discussion has been incited in technical societies and the technical press.

Secretary of Commerce Hoover states that the superpower report has stimulated the desire for similar studies in the Pittsburgh-Chicago area and in other sections.

Appointment of A. B. Houghton as Ambassador to Germany Confirmed

The choice of a manufacturer as Ambassador to Germany is of general interest to American industry and in this case, of particular interest to the chemical industry. In selecting Alanson B. Houghton for that post, the President has picked a practical man who is thoroughly familiar with the chemical industries and who has made research one of the important features of his great glass-making enterprise at Corning, N. Y. The laboratory that he maintains in connection with his glass works is said to be the most complete of its kind in the world.

Mr. Houghton was born in Cambridge, Mass., in 1863. His preliminary education was obtained at St. Paul's School at Concord. He specialized in economics at Harvard and was graduated from that institution in 1886. Shortly after his graduation he continued his study of economics in Europe. Three years of that time were spent in Germany. On his return to the United States he entered the glass works in one of the most humble capacities and learned the business in the plant of which he finally became the head. In 1918 he was elected to Congress. For 2 years he served on the Foreign Affairs Committee, after which he was chosen for membership on the Ways and Means Committee. He took an active part in the framing of the Fordney tariff bill. His intimate knowledge of the industrial situation in Germany made it possible for him to interpret to the committee many phases of the German situation which had a bearing on tariff making.

New Jersey Chemical Society Hears Prof. Hill and R. H. McCready

An interesting discussion of some of the peculiar properties of silver perchlorate was presented before the New Jersey Chemical Society in Newark, N. J., Feb. 13, by Arthur E. Hill, professor of physical chemistry at New York University. Besides a description of this and other little-known salts related to it, the speaker pointed out some of the possible practical applications of these properties. He suggested the possibility of using the salt in the determination of water in gasoline and for the quantitative estimation of aniline.

Robert H. McCready, publisher of *Chemical Age*, New York, described some of the features of his recent trip to Germany, emphasizing the apparently prosperous condition of the population.

Interest in Power Company's Offer Overshadows Ford Proposal

With the submission of a bid for Muscle Shoals by the Alabama Power Co., the discussion of the project has taken on a new interest. The hearings in progress before the House Committee on Military Affairs had excited very great interest since their inception on Feb. 9. Apparently, nine members of the committee have not been convinced that the Ford proposition should be accepted. Seven members are avowedly for the acceptance of the offer, while the five remaining members can be classed as doubtful.

From a chemical standpoint, most interest centers around the testimony of Richard C. Tolman, director of the Fixed Nitrogen Research Laboratory of the Department of Agriculture. Dr. Tolman made a clear and complete statement concerning the kinds of material that can now be manufactured at the nitrate plant and the possible future development of other materials such as fertilizer, urea and nitroguanidine. He described the changes that would be necessary in the plant to produce these different products and expressed the opinion of the laboratory that the plant could not be made to pay expenses if run to produce ammonium sulphate at its present market price.

Offer by Alabama Power Co.

The Alabama Power Co., Birmingham, Ala., has submitted an offer to the secretary of war which seems to offer advantages not presented in previous offers. The company proposes to take out a license under the federal water-power act under which it will complete the construction of Wilson dam and power house at its own expense. The company offers to furnish free to the government or anyone it may designate, from the hydro power plant, 100,000 hp. as required for the production of fertilizers and munitions of war.

It is proposed that the company purchase the government's interest in the Warrior extension of the steam plant, substations, transmission line and the steam plant at Nitrate Plant No. 2, with the necessary rights of way, and to pay therefor the sum of $5,000,000, less an amount to be agreed upon to cover the cost of the locks and navigation structures at Wilson dam. Under the terms of the proposal, the government is to transfer to the licensee the Wilson dam property represented by its investment and commitments to date, free of liabilities and unencumbered. The locks and navigation structures would be conveyed to the government in fee on completion of construction. In accordance with the water-power law, the project covered by the license would be subject to recapture by the government at the end of 50 years and would be turned over to the government for the production of munitions at any time as may be judged necessary by the President.

House Considering Several Proposals Regarding Project

Senator Norris of Nebraska, chairman of the Senate Agriculture Committee, which will consider the Muscle Shoals lease project, proposes that the committee shall visit Muscle Shoals to take evidence and make a personal investigation as to the advisability of completion of the government improvement either by the government or by lease. He has introduced a resolution authorizing this investigation, which has been referred to the committee controlling Senate expenses.

Representative Jones of Texas has introduced in the House a bill to accept the Ford proposal to lease the plant.

The Association of Practical Inventors of New York has petitioned Congress asking that the War Department retain the nitrate plant for the establishment of national instruction, training, experimenting and testing bureau for explosive chemicals, instructors, testers, etc., in preparing chemicals used for explosive chemical purposes.

General Williams Before Military Affairs Committee

While no new points of great significance have been brought out during the Muscle Shoals hearing before the Military Affairs Committee of the House, the testimony has had the effect of concentrating attention on the more important phases of an intricate negotiation.

General C. C. Williams, Chief of Ordnance, emphasized that the Ordnance Department feels a very vital interest in fixation of nitrogen, and that it must use every endeavor to see it brought about. The guarantee embodied in the Ford offer to keep the plant in operation during the term of the lease was held by General Williams to be of greatest importance. To pay $11,000,000 for nitrogen preparedness is a very moderate sum, he said.

Will Not Reduce Fertilizer Cost

When Representative Parker of New Jersey stated that he was not impressed with the arguments to the effect that fertilizer could be made cheaper by the operation of these plants, General Williams stated that his estimates on the cost of ammonium sulphate produced at Muscle Shoals does not lead him to believe that the cost of fertilizer can be cheapened materially. He pointed out, however, that the fixation of nitrogen is in its infancy. In that connection he said: "Fixation of nitrogen is being studied constantly in all of the scientific countries. It is something all recognize as essential. The supplies in Chile are being exhausted and it probably will not be a great many years before that country no longer will be able to supply the needs of the world. Just which will be the successful synthetic method no one can say. Those who have studied the question differ as to the best process. They all agree that in the not far distant future the fixation of nitrogen will be on a commercial basis, just as the production of pig iron."

General Beach Favors Ford Offer

General Lansing H. Beach, Chief of Engineers of the Army, told the committee that one of the great difficulties in handling the Muscle Shoals proposition was the fact that no definite assurance could be given prospective bidders. He said Mr. Ford is the only one who would make a definite response under those conditions.

With regard to the 50-year limit on water-power leases, General Beach said it is not always advisable to apply a general rule. In the case of Muscle Shoals there are arguments for an exception. The territory tributary to Muscle Shoals, he pointed out, is not yet a thickly settled portion of the country. Manufacturing is not highly developed and the length of time that would be required to develop a market for the power must receive careful consideration. He said that it had taken 20 years to utilize all of the power at Niagara Falls in spite of the fact that it is in the heart of a great industrial section. Continuing, General Beach said: "I understand that Mr. Ford intends to utilize this secondary power in a way that we would have considerable difficulty in developing a customer. I believe he proposes to install electric furnaces. They would be used whenever the power is available and he could utilize the secondary power in that way to great advantage and do it immediately."

Secretary Weeks Repeats Former Views

The testimony of Secretary of War Weeks before the committee was practically a reiteration of points made in his statement in transmitting the offer to Congress, published in Chemical & Metallurgical Engineering for Feb. 8, 1922.

"I believe there will be in 20 years a large number of plants in the United States producing nitrates," he said. "It is going to be a very common process. Within a limited number of years there will be a great amount of nitrogen recovered from the atmosphere, so that the question of the government maintaining a plant for this purpose may not be vital.

"The whole essence of Mr. Ford's offer, in my judgment, is whether people are going to get fertilizer at lower cost than heretofore. If that phase of the offer were eliminated, I think quite as advantageous disposition could be made of this property."

Interior Department Research Appropriation

The Interior Department appropriation bill as reported to the House provides $40,000 for chemical and physical researches by the Geological Survey, which is the same appropriation as for the current year.

International Conference on Water Pollution by Vessels at Sea Proposed

Hearings were held Feb. 15 by the House Foreign Affairs Committee on a resolution of Representative Appleby to call an international conference to amend the maritime laws to prevent discharge of oil by vessels at sea, which is said to contaminate shore waters. This is a companion measure of the Appleby bill to regulate discharge of oil, chemicals, etc., in American waters. Government officials were heard by the committee, including legal authorities of the Departments of State and Commerce.

A.C.S. Plans Trip to Southern Plants as Preliminary to Convention

The Washington Section of the American Chemical Society is arranging for a special train to leave Washington Friday evening, March 31, to enable members to visit Kingsport, Tenn., and the Clinchfield region, Chattanooga, Tenn., and Muscle Shoals, Ala., and arrive in Birmingham, Ala., on April 3 for the annual convention of the society. Detailed plans have not yet been made for the entertainment at Kingsport, Tenn., and at Muscle Shoals.

Saturday will be spent either at Knoxville or at Chattanooga, probably at the latter city. The region around Kingsport, Tenn., has become an interesting industrial center and large plants, such as the Clinchfield Portland Cement plant, the extract plant and tannery of the Grant Leather Corporation, a large facebrick plant and the wood-distillation plant of the Tennessee Eastman Corporation, are in operation. An immense leather-working plant of the Simmons Hardware Co. and the new plant of the Corning Glass Co. are ready for operation, but are at present closed down. The Union Dye & Chemical plant has ceased operations. The plants which are in operation, however, are sufficient to give a very interesting day for members and it may be possible to extend the trip to South Clinchfield to view the Carbocoal process of the International Coal Products Co., which is the only going concern making use of processes of low-temperature distillation of coal combined with the production of briquetted solid fuel. The possibility of visiting this plant appears to be entirely a question of time. If visited, there will be a slight addition to the railroad fare. At Chattanooga there are important industrial plants, such as byproduct coke plants, electric furnace manufacture of ferro-alloys, cottonseed and peanut oil refining, hydrogenation of oils, alum plant, etc.

Permission has been obtained to visit the nitrate plant and water-power development at Muscle Shoals. This permission is limited to American citizens and to those who have no personal connection with or financial interest in the manufacture of cyanamide. Ladies and personal guests may accompany members.

The train is contingent upon 125 guaranteed fares. Early application should be made to secure accommodations desired. Tickets should be bought from point of departure, via Washington over the Southern and Norfolk & Western railroads, direct to Birmingham. If 350 people purchasing tickets by certificate plan are present in Birmingham at the meeting, a return ticket via same route may be purchased at one-half the regular fare. Extra tickets for side trips and for Pullman accommodations must be purchased in advance and check for same, made out to Charles L. Parsons, chairman of the committee, must accompany application. No application for space will be considered unless accompanied by remittance.

Extra railroad charges for side trips Johnson City to Kingsport and return and Chattanooga to Muscle Shoals will be $10.87. The Pullman fares for all four days will be $13.20 for upper berth, $16.50 for lower and $58 for drawing rooms. These charges for Pullman are made to cover necessary guarantees. If Pullman cars are filled, there will be rebate of any excess fare paid. Application for space must be made on or before March 20. If 125 applications accompanied by full remittance for extra fare and Pullman are not received by that date, the train will be abandoned and all remittances returned. If the train runs, no remittances will be returned for any cause, as they are part of the guarantee.

Industrial Developments of the Week Marked by Production Increases

Paper.—The Riverside Paper Co., Glastonbury, Conn., has increased production to a full-time operating schedule at its local mill. Orders on hand are said to insure capacity operation for at least 2 months.

The United Paper Board Co., Whippany, N. J., is arranging for the immediate resumption of operations at its Hanover mill, which has been shut down for about a year past. A large working force is being recruited.

The Eastern Manufacturing Co., Bangor, Me., is operating its paper mills at capacity, and reports that incoming orders are running at about 110 per cent of rated production. The pulp department of the company is operating at about 65 per cent of normal.

Leather.—The Dietz Leather Co., Lynn, Mass., is completing a new beam house at its tannery and plans to place the structure in service at once. The capacity will be increased by about 300 dozen skins a day.

Every leather plant at Wilmington, Del., is now in operation and a new tannery at South Wilmington will commence operations at an early date. One of the largest local plants is now soaking 1,400 to 1,600 skins per day, or more than double the average daily amount during the year past.

The Greiss-Pfleger Tanning Co., is operating its two plants at Chicago, Ill., and Waukegan, Ill., at full capacity.

The Widen-Lord Tanning Co., Danversport, Mass., is operating its plant at capacity, with daily production totaling about 3,500 hides.

The Northwestern Leather Co., Boston, Mass., is operating at all of its tanneries at full capacity, including the plants at Portville, N. Y., Sault Ste. Marie and Manistique, Mich.

Ceramic.—The Maddock Pottery Co., Trenton, N. J., manufacturer of chinaware, is operating at full capacity, and has orders ahead to maintain operations indefinitely.

The Glen-Gery Shale Brick Co., Reading, Pa., has made a number of extensions and improvements in its plant to increase the production to more than 210,000 bricks per day. Capacity operations will be maintained.

Glass.—The Greensburg Glass Co., Greensburg, Pa., has resumed production at its plant after a shut-down of several months. Capacity operations are planned throughout the summer.

Six general glass plants in the Charleston, W. Va., district have resumed operations, giving employment to about 1,500 men. Three window glass plants have also started up, employing approximately 850 men.

Tin.—The McKeesport Tin Plate Co., McKeesport, Pa., began operations under a full-time schedule on Feb. 12, for the first time in several weeks. The plant is giving employment to about 3,500 men.

The American Sheet & Tin Plate Co. is operating at thirty of the forty hot mills at its Shenango, Pa., works. At the Newcastle, Pa., plant, twelve of the twenty hot mills are in active service.

Iron and Steel.—The Gulf States Steel Co. has resumed operations at its blast furnace at Birmingham, Ala. The unit was blown in Feb. 7.

The British Empire Steel Corp., Glace Bay, Nova Scotia, has resumed operations at its local plant on a full-time schedule.

The Wheeling Steel Corporation, Wheeling, W. Va., has resumed operations at three mills at Yorkville, Ohio, effective Feb. 7. The plant has been closed since last June.

The Trumbull Steel Co., Youngstown, Ohio, is working at 90 per cent capacity at its different plants. The entire battery of ten tinplate mills at the Liberty plant is in operation.

The Inland Steel Co., Chicago, Ill., is planning to start its new rail mill at the East Chicago, Ind., works, on March 1, with initial production on a 70 per cent basis. The mill will have a capacity of about 15,000 tons of finished rails per day.

Copper.—The Phelps-Dodge Corporation has placed three copper furnaces in operation at its Copper Queen smelter, Douglas, Ariz.

The Calumet & Arizona Mining Co. has resumed operations at two reverberatory furnaces at its smelter at Douglas, Ariz.

Engineering Foundation Board Considers Steps to Encourage Research

At the meeting of the Engineering Foundation Board on Feb. 9, a communication from Byron E. Eldred, well-known mechanical engineer and inventor, was presented proposing the establishment of an organization for the encouragement and development of meritorious research and invention. It is proposed to establish a department under the direction of an experienced engineer to furnish to inventors information, advice and financial assistance, to examine suggestions and inventions offered, to develop ideas believed to be of value and to obtain patents for and commercialize inventions which have passed thorough examination. The proposal includes the formation of a board of review composed of eminent engineers, scientists and patent attorneys and a board on commercialization of inventions to be composed of business men, industrialists and bankers. It also suggests the formation of a large endowment fund, the income of which would support the work and which would be increased by participation in the emoluments of successful inventions.

The board referred Dr. Eldred's suggestion to a committee of four consisting of Bancroft Gherardi, H. Hobart Porter, E. D. Adams and John H. Barr.

Sectional Meeting American Society for Steel Treating

Members of the New England and Seaboard Chapters of the American Society for Steel Treating will hold a sectional meeting at the Hotel McAlpin, New York City, on Friday, March 3. Technical sessions will be held at 2 and 8 p. m., and an informal dinner will be served at 6 o'clock. Papers on "Cold-Headed Bolts," "Influence of Mass in Heat-Treatment," "Magnetic Testing of Chain," "Stainless Steel," "A New Heat-Treating Alloy," "Perfecting a Drop Forging" and "The Manufacture of Steel" will be read and discussed.

All those interested in metallurgy and heat-treatment of steel are cordially invited to attend, whether members of the society or not.

Personal

E. T. Allen of the Geophysical Laboratory, Washington, D. C., addressed the Chemical Society of Washington on "Chemical Aspects of Volcanism" at the regular meeting of the section on Feb. 9.

S. E. Beach has been re-elected president of the Sun Oil Co. of California, Los Angeles, Cal.

F. E. Carroll, former representative of the Goodyear Tire & Rubber Co. in San Francisco, has been appointed Pacific Coast manager for the New York Lubricating Oil Co., with headquarters in San Francisco.

Dr. H. S. Davis has resigned his industrial fellowship at the Mellon Institute of Industrial Research, Pittsburgh, Pa., to accept a position on the research staff of Arthur D. Little, Inc., of Cambridge, Mass.

Arnold M. Eastman is now in charge of all chemical work at the plant of the Upson Co., Lockport, N. Y.

Charles H. Eldridge is now with the non-ferrous metallurgy section of the Bureau of Mines, Pittsburgh, Pa. For the past 4 years he was associated with Dr. C. G. Fink in the development of an insoluble anode now used by the Chile Exploration Co.

G. V. Geisler, export manager for the American Vulcanized Fiber Co., Wilmington, Del., has been appointed chairman of the Southern States committee of the Export Managers Club of New York.

Grosvenor M. Jones, who before 1913 was engaged in a special investigation in Washington in behalf of the American Paper and Pulp Association and since then has been with the Bureau of Foreign and Domestic Commerce, has taken charge of the latter's new paper division. He was assistant director of the Bureau of Foreign and Domestic Commerce from February, 1918, to August, 1919.

Warren A. King, president of the King Chemical Co., Bound Brook, N. J., has been re-elected president of the Manufacturers' Council of the State of New Jersey.

Eric A. Lof, industrial engineer and specialist of the power and mining engineering department of the General Electric Co., had the Royal Order of Vasa conferred on him by the King of Sweden, in recognition of meritorious service to his government.

Prof. J. H. Mathews, chairman of the department of chemistry, University of Wisconsin, addressed the Purdue Section of the American Chemical Society, Feb. 9, on the subject "Some of the Research Methods and Research Problems of Photochemistry."

Herman C. Mueller, head of the Mueller Mosaic Co., Trenton, N. J., gave an interesting address before students of the local Industrial Art School and other guests in the auditorium at the institution, Feb. 8, on the subject of "Industrial Training From the Standpoint of the Manufacturer and the Workman."

C. W. Sutton has been re-elected president of the American Vulcanized Fiber Co., Wilmington, Del.

Herbert Talley, chief engineer of the Hercules Powder Co., has resigned his position to become the operating head of the United States Powder Co. of Terre Haute, Ind.

H. G. Thiele, formerly with the Oliver Continuous Filter Co., is now connected with the Engineering Structures Co., Call Building, San Francisco, specializing on structural erection.

Dr. J. C. Witt, of Chicago, has been called into consultation by the Bureau of Mines to co-operate in research on portland cement-manufacturing processes.

Obituary

William A. Barstow, president of the Union Tank Car Co., New York, died recently at his home in West Orange, N. J., of pneumonia.

William James Comstock, for many years instructor in organic chemistry at the Sheffield Scientific School of Yale University, died Jan. 24, at St. Raphael's Hospital, New Haven, Conn., after an illness of 5 weeks. He was born at Toledo, Ohio, June 15, 1860; was graduated from Sheffield Scientific School in the Class of '79, was a Fellow in Chemistry at Johns Hopkins in 1881, and from 1882 to 1887 studied in Germany at the University of Munich. On his return to the United States he became an instructor at Yale, where he spent most of the active portion of his life.

William H. Gould, president of the Hoboken Paper Mill Co., Hoboken, N. J., died Feb. 4, following an illness of many months. He was sixty-eight years of age.

William C. Sargent, for 22 years secretary and also a director of Chain Belt Co., Milwaukee, Wis., died suddenly on Feb. 5 as the result of heart failure. He was seventy-three years of age and had been in ill health for several years. Mr. Sargent, prominent in industrial circles of Milwaukee and St. Paul, had a wide national acquaintanceship. He was born at Troy, N. Y., Feb. 2, 1849. In 1871 he moved west, locating at St. Paul, where he organized the De Cou, Corliss & Sargent Co., manufacturer of sash and doors. He later became affiliated with the St. Paul Harvester Co., and met C. W. Le Valley, who later founded the Chain Belt Co. of Milwaukee. This meeting was the beginning of a long business association, for in 1900 Mr. Sargent went to Milwaukee to become secretary and later a director of the Chain Belt Co. He was also a director of the Federal Malleable Co., West Allis, Wis. His father was one of the founders of the Terre Haute, Alton & St. Louis R.R. Mr. Sargent established many of the early business connections of the Chain Belt Co., a large number of which are still among the company's jobbers.

Market Conditions

IN CHEMICAL, METALLURGICAL AND ALLIED INDUSTRIES

A Survey of the Economic and Commercial Factors That Influence Trade in Chemicals and Related Commodities—Prevailing Prices and Market Letters From Principal Industrial Centers

Annual Reports and Financial Statements

We are now in the midst of the season of annual reports. The columns of the business papers are crowded with figures from financial statements and consolidated balance sheets. Such compilations of profit and loss and assets and liabilities in themselves mean but little to the uninitiated, but to the stockholder, banker or investor for whom they are intended they offer a ready means for appraising the stability of a company's finances. To the average engineer they may be almost void of meaning, but the financier familiar with the companies' policies uses them as an accurate check upon efficiency in operation and management.

At this time, perhaps more than any other, is the layman finding it difficult intelligently to interpret business statistics. The terrific decline in commodity prices has often necessitated radical revision of company policies. Inventories have had to be written down to replacement values. Stocks of finished goods have had to be carried at current manufacturing costs. Properties have had to be evaluated at a time when actual market values are probably nonexistent.

The condensed income statement derives its principal value as an index of general tendencies. However, in these days of business depression, comparison with previous years has lost much of its significance. Some sort of mental correction has to be made for relative values. The same thing that applies to inventories is equally applicable to reserves and to accounts payable and receivable. Furthermore, shutdown expenses, excessive depreciation and many other unusual items figure prominently in this year's balance sheets.

According to the policy pursued by some companies, it is customary to furnish stockholders and the general public with summarized reports of the year's activities in production and distribution. These are usually of real value to those interested in the general study of business conditions in the different industries.

During the past week a number of prominent chemical and metallurgical firms have made public the reports of their operations during 1921. Statements taken from some of these of more general interest are summarized in the following paragraphs.

The Hercules Powder Co.

The Hercules Powder Co. is one of the companies whose annual financial statement is accompanied by an illuminating explanatory report. Thus at the close of its ninth year, President R. H. Dunham of the Hercules company has presented a consolidated report showing the 1921 operations of that company, together with its subsidiaries, the Yaryan Rosin & Turpentine Co. and the Hercules Explosives Corporation of New York. The last-named corporation represents the entire assets and business of the former Aetna Explosives Co., Inc.

New Facilities Established

"This purchase," says President Dunham, "brought to the Hercules company manufacturing facilities and established business equal to approximately one-half its own in dynamite and one-quarter in black blasting powder. Also new facilities were obtained for the manufacture of blasting caps sufficient to supply not only the business acquired from the Aetna company but also all such requirements formerly purchased from other manufacturers." Furthermore, these manufacturing facilities are now so favorably located that it is possible to compete in the markets of practically every state in which there is a substantial consumption of explosive materials.

Naval Stores Division

In referring to the manufacture of naval stores—rosin, turpentine and pine oil—President Dunham reported that the company's plants were shut down early in 1921 with stocks sufficient to supply customers' reduced requirements for several months. During September the plant at Brunswick, Ga., was put into operation and this branch of the company's business is now operating without loss notwithstanding the very low prevailing prices, which are generally conceded to be below the cost of production by the ordinary method of obtaining rosin and turpentine from the living trees.

The Year's Profits

"Largely as a result of such economies," says the report, "as well as reductions in salaries and wages, the quarterly statements have shown steady improvement from a net deficit before the preferred dividend in the first quarter to the earning in the last quarter of a slight excess over the quarterly common dividend paid in December."

The Hercules company still retains at the close of 1921 a profit and loss surplus double its outstanding common capital stock, notwithstanding that the common dividends for the first three quarters were paid out of previously accumulated surplus. Because of the conservative dividend policy in the period of large earnings during the early war years and the accumulation of this large surplus equity belonging to the common stock the directors have felt that the common dividend should be continued while the company's financial position permitted, even though, for a reasonable time, the current net earnings should fail to equal such dividends.

Annual Earnings and Dividends

The amounts available for dividends and those paid on common stock, together with the net earnings on the investments, are shown in the following table adapted from the company's financial statement:

Year	Available for Dividend Equivalent to Annual Rate on Common Stock, Per Cent	Dividends Paid During Period on Common Stock, Per Cent	Net Earnings From All Sources Equivalent to Annual Rate on Total Investment, Per Cent
1913	15.65	3.00	9.52
1914	14.32	8.00	8.55
1915	63.18	16.00	13.97
1916	227.75	95.00	46.54
1917	76.19	70.00	17.88
1918	27.15	17.00	5.43
1919	16.86	16.00	5.09
1920	1.02	16.00	1.57
1921	3.48	12.00	2.19

CHEMICAL & METALLURGICAL ENGINEERING'S WEIGHTED INDEX OF CHEMICAL PRICES

Base=100 for the year July 1, 1913, to June 30, 1914

This week	149.05
Last week	147.46
February, 1921	166
February, 1920	252
April, 1918 (high)	286
April, 1921 (low)	140

The phenomenal increase in the price of linseed oil from 78c. to 86c. per gal. and a lesser rise in cottonseed oil are directly responsible for this week's higher index number. Slightly lower prices were reported for methanol, formaldehyde, caustic soda and crude potassium carbonate.

International Nickel Co.

The International Nickel Co. reported a deficit, after charges and federal taxes, of $641,678.11 for the 9 months ended with the calendar year. This is to be compared with net profits of $2,620,873 earned on the $41,834,600 of common stock in the corresponding period in 1920. Earnings were $143,714, as against $4,415,774 in the preceding year. Accounts payable, including tax reserves, amounted to $1,122,977, compared with $1,786,674.

The consolidated general profit and loss statement for the 9 months ended Dec. 31, 1921, follows:

Earnings		$143,713.96
Other income		220,560.73
Total income		$364,274.69
Administration and general expense	$311,874.17	
Reserved for United States and foreign taxes	70,128.01	382,002.18
Net income (deficit)		$17,727.49
Maintenance and shutdown expense of plants not operating	$228,266.09	
Depreciation and mineral exhaustion	395,684.53	623,950.62
Deficit		$641,678.11
Dividends		$401,067.00
Balance (deficit)		$1,042,745.11

Armour Leather Co.

The annual report of the Armour Leather Co. shows a deficit of $7,564,196 for the year 1921. This compares with a deficit of $4,313,653 in the previous year.

In his report to the stockholders, President Henry W. Boyd calls attention to the company's conservative policy in the purchasing of hides during the period of highly inflated prices. In this connection he continues: "We made the largest purchases of hides in our history in April, 1921, at the lowest prices prevailing in 15 years, and have been in the market often since.

"Our Sheboygan plant, which was destroyed in January, 1920, was rebuilt last year and resumed operations during 1921, its output meeting excellent demand.

"With our hides inventoried at cost and leather at the market, we made an operating profit during the last quarter of $869,000. The first quarter of this year will also show an operating profit. We are of the opinion that the hide and leather markets are sound and the remaining three-quarters of 1922 will show profits."

United States Rubber Co.

In a letter to the stockholders of the United States Rubber Co., C. B. Seger, chairman of the board of directors, declared that the annual report of the company will show a net profit of $470,817. This is in spite of a decrease of approximately $18,000,000 in the income from sales, caused by the drastic reduction in prices made after Jan. 1, 1921.

Mr. Seger stated that the volume of the company's business during 1921, expressed in tonnage rather than in dollars, was entirely satisfactory in view of the general business depression.

"The company closed the year in a strong financial condition," he continued. "Substantial liquidation having been effected, overhead expenses having been reduced to the minimum consistent with efficient operations, the company is in a strong position to meet the future."

Foreign Trade of the United Kingdom in 1921

The value of imports and exports of chemicals and allied products for Great Britain during 1920 and 1921 are shown in the following table taken from the *Official Board of Trade Journal* of Jan. 19, 1922.

Classification	Imports c.i.f. Value £1,000 Sterling 1920	1921	Exports of British Manufacture f.o.b. Value £1,000 Sterling 1920	1921
Chemicals, drugs, dyes and colors	34,329.5	12,682.2	40,535.7	19,057.3
Oils, fats and resins	76,853.3	56,589.2	13,626.4	5,230.4
Leather, and manufactures of	20,445.1	8,666.5	11,664.9	4,760.5
Paper and cardboard	30,243.7	11,601.3	12,810.4	7,736.4
Rubber goods	7,102.5	4,919.7	11,520.2	4,662.4
Earthenware, glass and abrasives	11,113.2	7,014.3	18,290.7	12,080
Iron and steel and manufactures of	29,016.7	22,887.4	128,907.4	63,772.4
Non-ferrous metals and manufactures of	39,132.6	18,467.6	25,781.8	11,733.7

The New York Market

NEW YORK, Feb. 20, 1922.

Interest in the chemical market during the past week has been limited to special items. Foreign buying has featured these commodity markets and there has been an appreciable increase in the aggregate volume of export sales. Dealers in caustic soda have been successful in obtaining a considerable portion of this business and sales were reported to Japan, Italy and South American countries. The advancing exchange has apparently broadened the field for export business. Copper sulphate is another item that has been sold in quantities sufficient to tax the capacities of leading producers. Italy and Greece are large buyers at present. Some small transactions were recorded to South America and are very significant because these countries have practically ignored American blue vitriol during the past year.

GENERAL CHEMICALS

Arsenic—Dealers report odd-lot sales in this item at 7@7¼c. per lb. on spot. Producers are not very anxious to shade 7½c. and report moderate orders at this figure. The present market, as a whole, is in a very healthy position, owing to the scant supplies and higher prices abroad.

Bleaching Powder—Producers quote the market at 2@2¼c. per lb. for large drums f.o.b. works. The demand has shown some improvement and the general market is firmer.

Bichromate of Potash—Leading factors are lower in their views and quote the market at 10½@10¾c. per lb.

Bichromate of Soda—Dealers were not anxious to quote below 7¾c. per lb. for spot material at the close of trading, with the general range around 7¾@8c. per lb. A fairly active call was noted to the consuming trades.

Carbonate of Potash—While some importers are quoting the 80-85 per cent material at 4@4½c. per lb., others are shading this figure and are offering spot goods as low as 3½c. Activity in this item has been very dull since the beginning of the year and keener competition has arisen.

Caustic Soda—Export inquiries continue to reach the market and sales are going through, but the majority of these are for small quantities. Leading dealers quote $3.25 per 100 lb. f.a.s. New York and in some quarters it was intimated that a shade under this figure might be done on business of a sizable proportion. Prices remain unchanged at the works.

Copper Sulphate—The demand for this chemical has improved during the past week. Export inquiries have reached the market and some of the larger producers have booked considerable business with Greece and Italy. American producers have been able to procure this business only through very close bidding. The domestic inquiry has not been very active, although the farmers are expected to come into the market in the near future. The general tone is firm with prices unchanged.

Nitrite of Soda — This chemical has been one of the leading features of the week's activities. Absorption of spot supplies has strengthened the market and some of the largest sellers have withdrawn from the market. While odd lots could possibly be purchased in a limited way at 7¼c. per lb., producers are firm at 7½c. The demand has shown considerable activity.

Prussiate of Soda—The limited spot supplies and improved demand have created a stronger market for this product and it is very doubtful if better than 18½c. per lb. could be done at present. February shipment was quoted at 17¼c. and March shipment at 17c. per lb. c.i.f. New York.

Soda Ash—Dealers report few inquiries on spot. Light ash in bags is offered in carload lots at $1.65 per 100 lb. and in barrels at $7.90. Smaller quantities demand a higher price. Producers quote light ash at $1.27½ per 100 lb. in single bags, basis 48 per cent, f.o.b. works.

Linseed Oil—Owing to the strengthened position of flaxseed, linseed oil took a sensational rise during the past few days and advanced during the week from 78c. to 86c. per gal. Imported material has been difficult to locate at any reasonable figure and as a result buyers were not inclined to purchase either domestic or foreign goods at the high prices.

The St. Louis Market

ST. LOUIS, Feb. 16, 1922.

There are no developments of great importance to mention at this time. Conditions in this market continue on the road to improvement. Confidence is gradually being restored, and buyers are more liberally inclined in covering their requirements. There have been very few price changes during the last period, and the general trend of the market is upward.

Alkalis—There is a slight decline on caustic soda. Carloads, 76 per cent, solid, are quoted at $3.40 per 100 lb., f.o.b. point of production, but 1- to 10-drum lots can be had for $4@$4.10 f.o.b. consumer's door. Flake, 76 per cent, in carloads is $3.75, f.o.b. point of production, with the 1- to 10-drum lots at $4.40@$4.50 per 100 lb., f.o.b. consumer's door. Light soda ash, 58 per cent, is still to be had at the previous price $2.40@$2.75 in less than carlots, carloads at about $1.85 f.o.b. point of production. Sal soda shows no change either in demand or price, and is quoted at $2@$2.25 per 100 lb. Bicarbonate of soda is moving slowly at the same price of $2.75 per 100 lb. in barrels.

General and Special Chemicals—While the demand for citric acid since the decline has not shown any great improvement, the season for this material is opening and larger stock should be carried. Acid gallic and pyrogallic continue to be quite active. Acid tartaric is again coming to life with prices firm. White arsenic is being quoted in carlots at 7c. St. Louis with one producer sold up. The increase in the demand for bromides is noticeable and orders of larger volume are passing. Ammonia water, 26 deg. U.S.P. is moving through regular channels. Carbon bisulphide prices are very firm with a brisk demand. The decline in prices on carbon tetrachloride about 2 weeks ago has not stimulated buying to a great extent, the demand being routine. The market on copperas remains the same, and the demand is still beyond manufacturers' output. Glycerine continues firm and in good demand at 16½c. in drums for spot goods; practically nothing is being done in the way of contracts. Owing to the continued increase in the sterling exchange, manufacturers advanced their prices yesterday on all iodide salts, with demand very good. Zinc sulphate is still being quoted at 3@3½c. per lb., f.o.b. point of production, with a fair demand.

Vegetable Oils and Naval Stores—The vegetable oil market shows a very firm condition with no declines, and stiff advances in linseed oil, which is now being held at 89c. basis raw oil, no futures accepted. Castor oil continues firm and in good demand at 13c. per lb. in drums. Turpentine is quoted at 96½c. in single barrels for pure gum spirits, the lowest price since our last report having been 93½c.

Paint Materials—Conditions in the barytes market remain practically as they were, so far as price is concerned, but there is improvement in the demand. Prices are quoted at $23@$25, cooperage included, f.o.b. St. Louis, for highest grade water-floated material. Domestic lithopone is apparently coming into its own again. Local producers report that they are practically out of stock, while a year ago stocks on hand were considerable. Zinc oxide is improving slightly, with demand fair and no price changes reported.

The Iron and Steel Market

PITTSBURGH, Feb. 17, 1922.

A particularly sharp increase in steel production occurred this week, the present rate being certainly well above 26,000,000 tons a year, and possibly as much as 28,000,000 tons. Our last report indicated that the average rate during January was about 22,750,000 tons.

There has been a very moderate increase in demand for practically all steel products since the first of the year. The particular jump in production this week seems to be due in part to the scheduling of rail mills in the Pittsburgh and Chicago districts to a good rate, caused not by strictly new buying but rather by specifying against contracts placed several months ago. There is also increased production of steel against orders for cars placed in 1921.

A point in analysis of the steel situation, as pointed out last week, is that in general the buying of steel is for very prompt shipment, and hence the best measure of market activity is the rate of steel mill operation. This can be estimated as a total, while the synthesis of market activity in different steel products, among different classes of consumers and in different parts of the country, is naturally not very precise. Technically, a disturbing element is this production of railroad material, since it does not represent hand-to-mouth buying as is the case with other steel products, hence cannot be counted upon with the same certainty.

Were it not for this element, the fact that steel ingot production has probably reached a rate of close to 28,000,000 tons a year would be of transcending importance. Production was at 11,000,000 tons a year last July, and rose, with the autumn demand, to 23,000,000 tons in October and November. A jump to a point so much higher, when spring is still several weeks distant, would indicate an extremely promising pace of improvement. No such continued rapid increase can be expected. With last autumn's demand measured by a 23,000,000-ton rate of ingot production, the industry may well be satisfied if it maintains an average rate, February to June inclusive, between 25,000,000 and 30,000,000 tons. The summer, no doubt, will be dull. Next autumn should bring a still higher tide.

STEEL PRICES

As indicated in previous reports, competition between mills became much keener just after the first of the year. The price competition did not consist, to any great extent, in naming new extremes for large orders, but was rather along the line of making concessions from regular prices for smaller orders. In bars, shapes and plates the regular or open market has been 1.50c. for more than 2 months, while the average price of all sales has been falling. Concessions have now extended to such small orders that the general market is more properly quotable at 1.40c. than at 1.50c., a price now reserved for small orders. Concessions below 1.40c. are altogether exceptional, but using the price as a general Pittsburgh basis there are departures in various sections, representing really a departure from Pittsburgh basing. The seller realizes, f.o.b. his mill, more than the Pittsburgh price, but does not get the full advantage of his location as he did when selling on the "Pittsburgh plus" system. Thus some Eastern mills have sold at above 1.50c. f.o.b. mill, when the same delivered price would have netted the Pittsburgh mill less than 1.40c.

Sheet prices are very well maintained at 2.25c. for blue annealed except in case of the heaviest gages, 3c. for black and 4c. for galvanized. This price steadiness has been one of the market phenomena for more than two months. Nails continue to be shaded to $2.40 in the case of large buyers, but mills insist that $2.50 is being obtained from the smaller buyers. Standard steel pipe is being shaded by 2½ to 5 per cent by most independents, this being to an extent a sort of trade custom.

PIG IRON

Despite a resale of basic pig iron on the basis of $17.75 valley recently, the producers seem strongly committed to maintaining the old price of $18. Bessemer remains at $19.50 valley, and is quite inactive. Foundry iron is not over-steady at its price of $19 valley. Jackson county furnaces have reduced bessemer ferrosilicon and silvery irons $2 a ton. These irons do not come to the Pittsburgh district to any extent, the preference being for the 50 per cent electrolytic, one advantage of which is that the buyer does not need to pay freight on a large percentage of iron.

Connellsville coke, reported a week ago as stiffening, has undergone a sharp advance, due to an actual demand developing in a situation which had secured a firm foundation. It is reported that a purchase of 75 carloads of prompt furnace coke has been made at $3.25 and another of 50 carloads at $3.50, the buyers, of course, being furnaces, while the market previously had been depending on the small-lot buying of miscellaneous consumers. Foundry coke is quotable at $4@$4.25, against $3.75@$4.25 formerly quoted. Dover furnace, Dover, Ohio, which blew in yesterday, contracted for its coke to July 1 at $3.25.

Industrial

Financial, Construction and Manufacturers' News

Construction and Operation

Alabama

BIRMINGHAM—V. L. Smith, 208 North 54th St., and associates are organizing a new company to construct and operate an oil-refining plant in this vicinity, with reclaiming department for byproducts manufacture. Plans will be prepared at an early date.

BESSEMER—The W. L. Lemly Foundry Co. is planning for enlargements and improvements in its plant. The company recently acquired the Columbus Foundry Co., Columbus, Ga., and its plant will be removed to the Bessemer site.

California

LONG BEACH—Hancock Bros., 620 East Anaheim Ave., operating a local metal works, are planning for the erection of a 2-story addition, 50 x 60 ft., to be equipped as an enameling and electroplating plant. The new building will adjoin the present plant structures.

FILLMORE—The California Asbestos & Kieselguhr Co., Los Angeles, recently incorporated with a capital of $1,000,000, is planning for the erection of a new plant in the vicinity of Fillmore for the manufacture of mineral insulation products. The company is headed by O. P. Posey, Pasadena, Cal.

LOS ANGELES—The Los Angeles Fertilizer Co. has awarded a contract to the Ralph E. Homann Co., 3720 South Park Ave., for the erection of a new 1-story building at 2643 Edwin St., 45 x 100 ft.

Connecticut

WALLINGFORD—The Wallingford Steel Co., recently organized with a capital of $200,000, is perfecting plans for the erection of its proposed new steel works on property acquired at the terminus of Valley St., to comprise three 1-story buildings, 100 x 130 ft., 50 x 110 ft. and 25 x 100 ft., respectively. F. A. Wallace and C. W. Leavenworth, both of Wallingford, head the company.

Delaware

LEWES—The Lewes Fertilizer Co. has awarded a contract to the Austin Co., Bulletin Bldg., Philadelphia, Pa., for the erection of a new 1-story plant, estimated to cost about $65,000. Work will be commenced at once.

Florida

CLERMONT—The Board of Trade is perfecting plans for the organization of a new local company to operate a glass-manufacturing plant, and has selected a site for the erection of a 1-story plant, 150 x 200 ft., to be equipped for the production of bottles, preserving jars, etc. The machinery is estimated to cost about $20,000.

Illinois

CHICAGO—The National Card, Mat & Board Co., 218 West Superior St., manufacturer of cardboard, paper products, etc., has awarded a contract to the Holton Seelye & Co., 140 South Dearborn St., for the erection of a 1-story plant at 4318-36 Carroll Ave., 100 x 140 ft., estimated to cost about $35,000. C. H. Crysler is president.

Indiana

MARION—The Indiana Fiber Co. has work under way on a number of extensions and improvements in its plant to double, approximately, the present capacity.

EDINBURG—The Union Starch & Refining Co. is considering tentative plans for the establishment of a soy bean oil-extraction plant in connection with its present works. A byproducts extension will also be erected.

Kansas

HUTCHINSON—The Carey Fiber Products Co., is planning for the rebuilding of the portion of its plant, destroyed by fire, Feb. 1, with loss estimated to be in the neighborhood of $35,000.

Kentucky

PAINTSVILLE—The Big Sandy Refining Co., recently organized, is planning for the erection of a new oil refinery on local site, with initial capacity of about 100 bbl. per day. The plant will utilize crude oil from the Berea field, Johnson County. Ralph Stafford is president; and Earl Stafford, secretary and treasurer.

Maryland

BALTIMORE—The Commercial Chemical Co. has leased space in the building at 23 Light St., and will establish a plant for the manufacture of denatured alcohol products and derivitives. Edward S. Tyler is president.

BALTIMORE—The American Concrete Tile & Products Co., 305 Gaither Bldg., will take bids early in March for the erection of its proposed new local plant, to be 1-story, 60 x 200 ft., and estimated to cost about $70,000, including equipment. John E. Springer is president, and John W. Ritter, secretary and treasurer.

BALTIMORE—The White Co., 206 Water St., manufacturer of paints and varnishes, is planning for the erection of a new 3-story plant, to be equipped primarily for the manufacture of paint products. It is proposed to commence construction at an early date. C. M. Stengle is president.

HAVRE DE GRACE—Norman Marritt and associates have acquired the property of the Maryland Flint & Feldspar Co., at Kalmia, near Havre de Grace, and plan for extensive operations.

BALTIMORE—Hynson, Westcott & Dunning, Charles and Franklin Sts., manufacturers of drugs, chemicals, compounds, etc., have awarded a contract to Hicks, Tase & Norris, 106 West Madison St., for the erection of a new 3-story plant, 50 x 150 ft., estimated to cost about $175,000, including equipment. Howard Sill, 11 East Pleasant St., is architect.

Massachusetts

CANTON—The George Grow Tire Co., 323 Columbus Ave., Boston, Mass., has awarded a contract to Coleman Bros., 49 Medford St., Charlestown, Mass., for the erection of a new addition to its rubber factory on Jackson St., Canton, 40 x 100 ft., estimated to cost close to $60,000. Work will be commenced at once.

Michigan

ESCANABA—B. C. Chatfield, Escanaba, is organizing a company to construct and operate a new local foundry for the manufacture of iron, brass and other metal castings. It will be located in the Iron Mountain district. Plans will be prepared at an early date.

Missouri

LEEDS—The Wilson Slaughtering Device Co., 511 American Bank Bldg., Kansas City, Mo., has commenced excavations for a new plant near Leeds, to be equipped for the manufacture of serums. It will consist of four units, each about 30 x 40 ft., and is estimated to cost about $50,000.

New York

BROOKLYN—The Perfect Brick & Hollow Tile Co., care of Silverman & Infanger, architects, 188 Montague St., is taking bids for the erection of its proposed new 1-story plant, 100 x 100 ft., on Grand St., estimated to cost about $50,000.

NEW YORK—The Fleischmann Co., 701 Washington St., manufacturer of yeast, has taken title to property on Mott Ave. near 157th St., 210 x 257 ft., for a consideration said to be $125,000, and will use the site for its proposed new 3-story laboratory building, 52 x 165 ft., estimated to cost about $250,000, instead of $150,000, as previously announced. Contract for erection has been let to the George A. Fuller Co., Flatiron Bldg., New York.

NEW YORK—Fire, Feb. 10, destroyed a portion of the plant of the Goldberger Plate Glass Co., 457-61 First Ave., with loss estimated at about $75,000.

POUGHKEEPSIE—The Corrugated Rubber Co., care of W. J. Beardsley, architect, 49 Market St., Poughkeepsie, is completing plans and will soon take bids for the erection of a new plant in the Fairview section, to be 1-story, 60 x 200 ft., and estimated to cost about $90,000.

NORTH TONAWANDA—The Board of City Commissioners will have plans prepared at once for a new filtration plant at the city waterworks, to cost about $250,000, including equipment. J. N. Chester, Pittsburgh, Pa., is engineer. The Board of Public Works is in charge.

Oklahoma

MUSKOGEE—The Muskogee Oil Refining Co., South Cherokee St., is planning for extensions and improvements in its oil-refining plant to cost about $200,000, including equipment.

Pennsylvania

PHILADELPHIA—The Bath Portland Cement Co., Finance Bldg., has completed plans and will call for bids immediately for the erection of a new cement-manufacturing plant at Sandts Eddy, Pa., utilizing a site acquired by the company a number of months ago. The plant will comprise a number of buildings and is estimated to cost about $1,750,000, including machinery. It will be electrically operated in all departments. The company has arranged a fund of $300,000 for extensions and improvements to its mill at Bath, Pa., including the complete electrification of this works. Louis Rafetto is president; and P. H. Hahneman, treasurer.

PHILADELPHIA — The Pennsylvania Synthetic Gas & Chemical Co., Witherspoon Bldg., has leased space in the building at Broad and Spring Garden Sts., for a local works.

LOCH HAVEN—The Queens Run Refractories Co., Inc., has been organized to take over and consolidate the Queens Run Fire Brick Co., North Bend Fire Brick Co. and the West Branch Fire Brick Co. The new organization will continue the operation of the different plants, and has plans under consideration for expansion. William Sleicher is president, and John F. Marshall, secretary.

Tennessee

JOHNSON CITY—The Crab Tree Corporation, Johnson City, is planning for extensive operations on feldspar, mica and kaolin properties in Mitchell and Yancey Counties, N. C. The company has a tract of about 2,500 acres of land and will erect a new grinding mill and other plant buildings. Equipment to cost in excess of $150,000, a portion of which has been ordered, will be installed. A housing development for operatives will also be established. Frank R. Scott is president.

Texas

MEXIA—The Humphreys-Pure Oil Co. is perfecting plans for the erection of its proposed new refinery at Port Neches, Tex., and plans to commence work early in the spring. It will have an initial capacity of about 40,000 bbl. of crude oil per day. A pipe line will be constructed from the Mexia fields to the plant. The refinery will cost close to $1,000,000. Col. E. A. Humphreys is president. The company is erecting a 3-story office building on Belknap St., Mexia.

SNYDER—Smith & Hamer, Snyder, have acquired a local site and plan for the immediate erection of a new leather tannery.

Utah

PARK CITY—The Silver King Coalition Co. has construction under way on a new concentrating plant and proposes to begin operations late in March. The machinery installation has been commenced.

Virginia

NORFOLK — The Robertson Chemical Corp. is planning for the rebuilding of its plant unit, recently destroyed by fire. Walter H. Roberston is president.

West Virginia

PARKERSBURG—Fire, Feb. 2, destroyed the local branch plant of the Biddle Concrete Co., Clarksburg, W. Va., manufacturer of sewer pipe, blocks, etc., with loss estimated at about $30,000, including equipment. John C. Biddle is general manager.

New Companies

THE DODGE CHEMICAL CO., Boston, Mass., has been incorporated with a capital of $50,000, to manufacture chemicals and chemical byproducts. Albert N. Lockhart is president; and C. F. Dodge, 20 Weban St., Boston, treasurer.

THE AMERICAN CELLO GLASS CO., New York, N. Y., has been incorporated with a capital of $100,000, to manufacture paper products, artificial silk and kindred specialties. The incorporators are R. Harris, T. T. Curran and C. W. Mitchell, 2 Rector St., New York.

THE JOHNSTON PAINT & GLASS CO., 8727 Grand River Ave., Detroit, Mich., has been incorporated with a capital of $25,000, to manufacture paints, oils, varnishes, etc. The incorporators are R. Fee Johnston, William C. and John L. Shepard.

THE GRANT CHEMICAL CO., Newark, N. J., has been incorporated with a capital of $25,000, to manufacture chemicals and chemical byproducts. The incorporators are Nathan Gelb, William M. and Lovett A. Grant, 790 Broad St., Newark.

JAMES C. DEERY, INC., New York, N. Y., has been incorporated with a capital of $10,000, to manufacture pulp products. The incorporators are J. C. and L. E. Deery, and J. A. F. Newton. The company is represented by A. Warshow, 464 Broome St., New York.

JEFFERY & SON LUBRICANTS CO., Greenleaf and Hartrey Aves., Evanston, Ill., has been incorporated with a capital of $500,000, to manufacture lubricating oils. The incorporators are E. R. and W. O. Jeffery, Sr. and Jr.

SAMUEL KIDDER & CO., INC., Boston, Mass., has been incorporated with a capital of $27,000, to manufacture chemicals and chemical compounds. George A. Spear is president; and George P. Nason, Medford, Mass., treasurer.

THE PENN-BEDFORD OIL CO., Johnstown, Pa., has been incorporated with a capital of $100,000, to manufacture petroleum products. Thomas H. Watt, Johnstown, is treasurer.

LEVIN & CO., INC., San Antonio, Tex., has been incorporated with a capital of $10,000, to manufacture greases, lubricants, etc. The incorporators are William Levin and W. P. Gee, both of San Antonio.

THE CHEMICAL INK CO., Brooklyn, N. Y., has been incorporated with a capital of $100,000, to manufacture chemicals, inks and affiliated products. The incorporators are J. A. Seixas, K. Dyer and W. H. Stieglitz. The company is represented by M. J. Moore, 141 Broadway, New York.

THE CHOLORO CHEMICAL CORP., New York, N. Y., has been incorporated under Delaware laws with capital of $200,000, to manufacture chemicals and chemical byproducts. The company is represented by the United States Corporation Co., 65 Cedar St., New York.

THE BIRMINGHAM METAL CO., 231 South Exeter St., Baltimore, Md., has been incorporated with a capital of $200,000, to operate a metal-refining plant and ore-reduction works. The incorporators are Charles H. Birmingham, Joseph C. Rintelen and John P. Simon.

THE S. L. AGOOS TANNING CO., INC., Boston, Mass., has been incorporated with a capital of $75,000, to manufacture leather. Samuel L. Agoos, 60 Amory St. Brookline, Mass., is president and treasurer; Norman D. Nepon is vice-president.

THE ESTATE OF JAMES R. SAYRE, JR., INC., Newark, N. J., has been incorporated with a capital of $728,000, to manufacture bricks and other burned clay products. The incorporators are M. H. Barker, E. M. Burbank and H. T. Brooks. The company is represented by Edward M. and Runyon Colie, 763 Broad St., Newark.

THE WESCO PRODUCTS CO., 39 South La Salle St., Chicago, Ill., has been incorporated with a capital of $25,000, to manufacture paints, cement preparations, etc. The incorporators are Thomas H. Maddock, Jacob H. Jaffe and Vincent J. Green.

THE LION OIL & REFINING CO., El Dorado, Ark., has been incorporated with a capital of $150,000, to manufacture refined petroleum products. The incorporators are F. H. Thwing, E. D. Ellison and George A. Todd, El Dorado. The last noted represents the company.

SNELL & PIERCE, INC., Syracuse, N. Y., has been incorporated with a capital of $100,000, to manufacture chemicals and chemical byproducts. The incorporators are A. W. Snell, H. O. Pierce and D. E. Alvord. The company is represented by Alvord & Brewster, attorneys, Syracuse.

THE ARIZON TRIPLE MOUNTAIN COPPER CO., Franklin, Tenn., has been incorporated under Delaware laws with a capital of $5,000,000, to operate a metal-refining plant for copper production. The incorporators are P. V. Channel, Franklin, Tenn.; J. C. Askew and C. F. Matthews, Nashville, Tenn. The company is represented by the Colonial Charter Co., Ford Bldg., Wilmington, Del.

THE PLYMOUTH PAPER PRODUCTS CO., Mount Vernon, N. Y., has been incorporated with a capital of $100,000, to manufacture paper goods. The incorporators are L. C. Smith, H. Moak and M. J. White. Holden & Cavanaugh, attorneys, Mount Vernon, represent the company.

THE DETROIT ELECTRO-METALS CO., Detroit, Mich., has been chartered under state laws to manufacture aluminum and other metal products, metal alloys and chemical specialties. The incorporators are Dennis Boyle, Clarence E. Lehr and Thomas F. Murphy, 217 Philip Ave., Detroit.

THE SHELL-UNION OIL CO., New York, has been incorporated under Delaware laws with a capital of $1,000,000, to form a merger between the Union Oil Co. of Delaware, 17 East 42d St., New York, and the Shell Transport & Trading Co., San Francisco, Cal., to operate oil refineries in California and other districts, and manufacture refined petroleum products of various kinds. Headquarters will be at the New York address noted.

THE NIAGARA INK CO., Albany, N. Y., has been incorporated with a capital of $500,000, to manufacture inks and affiliated products. The incorporators are E. W. Ladd, J. B. Condon and T. A. Brown. The company is represented by H. J. Crawford, attorney, Albany.

THE INDUSTRIAL DYESTUFF CO., East Providence, R. I., has been incorporated with a capital of $50,000, to manufacture dyes, chemicals, etc. The incorporators are Herbert L. Tobey, Simon Norman and John H. Caton, Jr., 96 Arnold Ave., Edgewood, R. I.

THE SOUTHWEST PULP & PAPER CO., Wilmington, Del., has been incorporated under state laws with capital of $2,500,000, to manufacture pulp and paper products. The company is represented by the Corporat'on Trust Co. of America, du Pont Bldg., Wilmington.

THE GLOBE PETROLEUM CO., Richmond, Va., has been incorporated with a capital of $5,000,000, to manufacture petroleum products. Sherwood E. Hall is president; and Frederic G. Bastian, secretary, both of Richmond.

THE STERLING-WELD CO., New York, N. Y., has been incorporated with a capital of $5,000, to manufacture aluminum and other metal products. The incorporators are W. H. Sterling, V. A. Whitla and E. F. Degruchy. The company is represented by C. M. Russell, 50 Church St., New York.

THE GOULD FIRE PREVENTION PRODUCTS CO., Wilmington, Del., has been incorporated under state laws with a capital of $500,000, to manufacture fireproof paints and other fire-resisting compounds. The company is represented by the Delaware Charter Co., 904 Market St., Wilmington.

POMEROY & FISHER, INC., New York, N. Y., has been incorporated with a capital of $250,000, to manufacture chemicals, paints and kindred products. The incorporators are A. P. Demarmon, S. Steinkamp and C. B. Grimes. The company is represented by Salter & Steinkamp, 140 Nassau St., New York.

THE BARIUM PRODUCTS CORP., Carbondale, Ill., has been incorporated with a capital of $40,000, to manufacture chemicals and metallurgical specialties. The incorporators are Robert Forsyth, J. H. Mitchell and R. A. Taylor. The company is represented by Herbert A. Hays, Carbondale.

THE RUSSELL CLAY MFG. CO., Wilmington, Del., has been incorporated under state laws with a capital of $600,000, to manufacture ceramic and burned clay products. The company is represented by the Corporation Service Co., Wilmington.

THE RED CIRCLE RUBBER CO., Wilmington, Del., has been incorporated under state laws with capital of $1,000,000, to manufacture automobile tires and tubes, and other rubber products. The company is represented by the Corporation Trust Co. of America, du Pont Bldg., Wilmington.

THE MORRIS TANNING CO., Peabody, Mass., has been incorporated with a capital of $100,000, to manufacture leather. Charles D. C. Moore is president; and Abraham Cohen, Beachmont, Mass., treasurer.

THE HAINES SHELLAC WORKS, INC., New York, N. Y., has been incorporated with a capital of $10,000, to manufacture shellac and kindred products. The incorporators are S. J. and J. Haines, and H. Maas. The company is represented by David Sobel, 136 William St., New York.

Capital Increases

THE DETROIT SOLUBLE OIL CO., Detroit, Mich., has filed notice of increase in capital from $50,000 to $150,000.

THE OSWEGO FALLS CORP., Fulton, N. Y., recently incorporated with a capital of $2,500,000, to manufacture pulp and paper products, comprising a merger of a number of mills in this section, has arranged for a bond issue of $2,100,000, for general operations, financing and expansion. H. L. Paddock is president.

LOUIS SACKS, INC., Wilson Ave., Newark, N. J., manufacturer of iron and other metal castings, has filed notice of increase in capital from $500,000 to $600,000.

THE ASBESTOS & MINERAL CORP., 1819 Broadway, New York, N. Y., has filed notice of a reduction in capital from $500,000 to $135,000.

THE RABE PIPE & FOUNDRY CO., Chattanooga, Tenn., has filed notice of increase in capital from $200,000 to $350,000. R. R. Rabe is president.

THE BARCO PETROLEUM CORP., 149 Broadway, New York, N. Y., a Delaware corporation, has filed notice of increase in capital from $3,000,000 to $12,000,000.

THE AJAX ENAMELING & FOUNDRY CO., Battle Creek, Mich., has filed notice of dissolution under state laws.

John S. Dickerson, trustee in bankruptcy for the AMERICAN TIN SMELTERIES, INC., has arranged for the sale of the company's smelting plant at Matawan, N. J.

THE WANDER & SONS CHEMICAL CO., Albany, N. Y., has field a petition in bankruptcy, with liabilities stated at $594,078 and assets $183,588. Frank M. Wright has been appointed receiver.

Coming Meetings and Events

AMERICAN CERAMIC SOCIETY will hold its twenty-fourth annual meeting at St. Louis, Feb. 27 to March 3, 1922.

AMERICAN CHEMICAL SOCIETY will hold its spring meeting at Birmingham, Ala., April 4 to 7, 1922.

AMERICAN ELECTROCHEMICAL SOCIETY will hold its spring meeting in Baltimore, April 27, 28 and 29, 1922. Headquarters will be at the Emerson Hotel.

AMERICAN FOUNDRYMEN'S ASSOCIATION will hold its next convention and exhibit at Rochester, N. Y., during the week of June 5, 1922. Meetings will be held in the spring instead of in the fall as heretofore

AMERICAN SOCIETY FOR STEEL TREATING will hold a sectional meeting, Friday, March 3, at the Hotel McAlpin, New York City. A sectional meeting will also be held at the Bureau of Mines auditorium, Pittsburgh, Pa., on May 25 and 26. The International Steel Exposition and Convention of the society will be held in the General Motors Bldg., Detroit, Mich., Oct. 2 to 7.

AMERICAN SOCIETY FOR TESTING MATERIALS will hold its twenty-fifth annual meeting June 26 to July 1, at Atlantic City, N. J. Headquarters will be at the Chalfonte-Haddon Hall Hotel.

INTERNATIONAL UNION OF PURE AND APPLIED CHEMISTRY will hold a meeting at Lyons, France, June 27 to 30.

IRON AND STEEL INSTITUTE (British) will hold its annual meeting on May 4 and 5 at the House of the Institution of Civil Engineers, Great George St., S. W., 1, London.

NEW JERSEY CHEMICAL SOCIETY holds a meeting at Stetters Restaurant, 842 Broad St., Newark, N. J., the second Monday of every month.

STAMFORD CHEMICAL SOCIETY, Stamford, Conn., holds a meeting in the lecture room of the local high school on the fourth Monday of each month, except June, July, August and September.

The following meetings are scheduled to be held in Rumford Hall, the Chemists' Club, New York: March 10—American Chemical Society, Nichols Medal; March 24—Society of Chemical Industry, regular meeting; April 21—Society of Chemical Industry (in charge), American Electrochemical Society, Société de Chimie Industrielle, American Chemical Society, joint meeting; May 5—American Chemical Society, regular meeting; May 12—Société de Chimie Industrielle (in charge), American Chemical Society, Society of Chemical Industry, American Electrochemical Society, joint meeting; May 19—Society of Chemical Industry, regular meeting; June 9—American Chemical Society, regular meeting.

Patent Legislation Will Benefit Industry

INDUSTRY will receive many direct benefits as a result of the passing and signing of the bill to relieve conditions in the Patent Office. As soon as the necessary appropriations can be made it will be possible to increase the force by 10 per cent and salaries by 45 per cent. As much as $450,000 per annum will be added to the payroll. These figures are not mentioned in a spirit of elation, because Congress has long been niggardly with the Patent Office and has neglected a self-supporting institution to the detriment of the country's business. The new salaries authorized are still inadequate, but they will afford sufficient relief to prevent a complete disintegration of the Patent Office staff.

When the full force of the new bill is in effect it will be possible to get prompter action on applications for patents. And with promptness will come a higher degree of efficiency that should reduce the amount of litigation that arises from hurried consideration of patent claims. Inventors will not be discouraged by interminable delay that has characterized Patent Office procedure for the past few years. This was coming to be a very serious matter, even threatening the acknowledged supremacy of the United States in stimulating the inventive genius of its people.

An important feature of the bill is an amendment enabling a patentee to recover cash damages for infringement of his patent. Hitherto it has been exceedingly difficult to obtain such damages, but the present bill provides for a means of accounting that simplifies matters and makes reasonable compensation a certainty.

All in all we may feel encouraged over the consummation of this legislation, but we should be constantly on guard to see that the Patent Office does not again fall into such dire straits.

Mr. Ford As a Catalyst

IT WOULD BE ironical if the sequence of events in the final disposition of Muscle Shoals should prove that HENRY FORD and his offer for the power and nitrate plants served merely to stimulate others to bring more acceptable proposals before the government. Such is likely to be the case, however, if we may judge from the terms on which the Alabama Power Co. has already proposed to buy the power plants and complete the Wilson dam under the federal water-power act.

We hold no brief for the Alabama Power Co. or for any other individual or corporation that may bid on these government properties, but it is gratifying to see in the power company's proposal a vindication of our contention that Muscle Shoals should be looked upon as two separate and unrelated projects, one a water-power development and the other a chemical-manufacturing plant. The power company in its bid proposes to complete the Wilson dam and hydro-electric power plants at its own expense and offers a fixed quantity of power per annum for government use. No reference is made to the nitrate plants. They would still be left at the disposal of the government either to be kept in standby condition for the Ordnance Department of the Army or sold to some private concern. In other words, the offer of the Alabama Power Co. is more attractive than that of Mr. FORD.

We may contrast the two in their vital points: Mr. FORD would have the government finance the completion of the power project; the Alabama Power Co. will finance its own operations. Mr. FORD asks a 100-year lease, with further prior rights on power at the end of that period; the power company asks only a 50-year lease, with provision for recapture of the project by the government at the end of that period. Mr. FORD offers $5,000,000 for the nitrate plants, the Gorgas-Warrior steam plant, the lime quarry and other accessories; the power company will pay an equal amount for the same accessories omitting the nitrate plants. In addition the power company offers to furnish free to the government, or to anyone it may designate, 100,000 hp. as required for the production of fertilizers and munitions of war and for research in connection therewith. In our judgment the contrast is sufficiently impressive to warrant the belief that the Ford offer will not be acceptable to the government.

A Final Word On the Bonus

IT HAD NOT been our intention to comment again on the soldier bonus, but letters from subscribers, published elsewhere in this issue, led us to give final consideration to the subject. It is evident now that Congress gave quite as much heed to the wave of opposition as it did originally to the supposed demand for the bonus, and the prospect of legislation is very remote. That the country will have none of it is apparent even to those who are not accustomed to keeping their political ears to the ground. In Congress, what was first supposed might prove a strong political weapon has assumed the properties of a boomerang.

Those who disagreed with our stand on this question have not refuted our principal argument, which is that legislation for a cash bonus will be an economic blunder. It is beside the point to refer to the action of individual states that have already passed bonus legislation. There are others that have not and will not. Doubtless those that have will wish they had not if a federal tax is now laid to pay a national bonus. Some of our critics cite the compensation that was paid to those who lost on war contracts and to others who were financially disabled by the war, and argue that the ex-service

man should be similarly compensated for loss of money and position. It would not be difficult to cite many instances of civilians to whom the war brought financial loss and for whom there is no hope of compensation. War brings its fortunes and misfortunes that cannot possibly be equalized or balanced. The country is sympathetic with the disabled soldier and feels that everything should be done to relieve his sufferings and rehabilitate him, but it is not moved by the same sort of sentiment for the able-bodied survivor.

Nor do we share the assurance of our correspondent who asserts that "business was not in the trenches." We can imagine some business men waxing eloquent in response to that challenge! But granting that business wasn't in the trenches during the war, it is today knee deep in the mire of economic readjustment that will only be made deeper and stickier by a bonus award.

If the general idea of a bonus of $500 or $600 were acceptable, we still think that the proposed method of distribution would be inefficient. As the plan now stands, it is about as fine a scheme as can be devised for dissipating hundreds of millions of dollars by paying it out in such small doles and at such intervals that the most of it will be squandered.

Three of our critics raise a point which, while it has no bearing on the bonus, ought not to pass without comment. They question the independence of thought and action on the part of members of our editorial staff. The only reply that need be made is that the editor is not subservient to higher authority in determining the policy of CHEM. & MET., nor are members of the staff under the slightest coercion to agree with the editor's views. If, as in the present instance, the entire staff is in accord, its members have sacrificed none of their independence, nor have they bowed submissively to a tyrannical authority. Editorial independence is one of the first requisites of a virile magazine.

Royal Houses In Chemistry

IT CERTAINLY is a pleasure to see the young fellows coming along. Somebody with great imagination "binds time" in science by adding his contributions to the records of human progress and then passes them on for future generations. The subjects endure, but the names change. Occasionally, however, there is a strain among families of men in which the gift for research perseveres and when we see it manifest itself in successive generations, it gives us an agreeable thrill.

Research seldom provides riches or palaces or even the appearance of luxury or ease. The truly great look like other men, and with a few curious exceptions they are modest and kindly and generous; inspired, as are all good men, with a sense of their obligations to contribute as much as they can. Despite the apparent democracy, however, they are aristocrats of the first rank, and their spiritual abode is in the temple of fame.

There is, for instance, ARRHENIUS—SVANTE ARRHENIUS. He has already done a giant's work. His fame is secure. And we wish him many years of continued research and the abundant joys of discovery. The name itself has a classic tang, and it does not surprise the student when he finds electrolytic dissociation and even a happy suggestion on the origin of life on earth coupled with it. It looms above the boundaries of nations. He is ARRHENIUS the First!

We call him the First, because there appears above the horizon of the great domain of Science a second of the line, OLOF ARRHENIUS, the son of SVANTE, and OLOF has lately been at work with THEODORE W. RICHARDS in the Wolcott Gibbs Memorial Laboratory at Cambridge. He presents a very acceptable contribution in the January number of the *Journal of the American Chemical Society* on "Quantitative Analysis by Centrifuge." The method has been used for special purposes and now he makes it more general for the rapid determination of calcium, magnesium and phosphoric, sulphuric and nitric acids.

> The precipitate obtained in the usual way is shaken with the mother solution and then transferred to tubes 2.5 cm. in diameter at the top, and provided with a steep funnel below leading to a capillary tube about 4 cm. long (and for compact precipitates only 1 mm. in bore). The precipitate is allowed to settle in the capillary stem. Many of these tubes are then centrifuged together, until the precipitate in each has attained a constant height, which is usually the case in less than half an hour. This column is read with a mirror scale to avoid parallax in reading. These columns are reduced to a weight standard by comparison with a precipitate similarly obtained from a known weight of the substance similarly treated.

Only a modest contribution, to be sure, and there have been others before it, but this one is potent for the convenience of chemists. It is likely to find its way into many laboratories, and to stay there. We can imagine, 'way off in the next century, some chemist coming home from his laboratory earlier than usual, and a greeting awaiting him the more ardent and agreeable because he came before he was expected. "Who helped you through with your work so soon?" is a question that may be put. And an answer that may be given is "ARRHENIUS the Second!"

Import and Export Of Nitrogen

CROSS-HAULING of commodities to satisfy unnecessary and unwarranted individual preference is a demonstrated economic waste. A similar economic extravagance occurs in simultaneous import and export of equivalent material. It is, therefore, of importance to the nitrogen-producing and the nitrogen-using industries of America to determine whether there is not now going on some such international movement of ammonia and nitrate compounds.

During 1921 there was imported into the United States approximately 370,000 tons of Chilean nitrate, valued at $18,000,000. During the same year about 103,000 tons of ammonium sulphate, valued at $6,100,000, was exported. These two items represent the major transactions in international movement of inorganic nitrogen compounds in which the United States is interested. In the imported nitrate there was about 55,000 tons of nitrogen. In the exported sulphate there was about 20,000 tons of nitrogen. In other words, about 36 per cent of the nitrogen that is imported is represented by equivalent exports of nitrogen in other forms.

There is no doubt that not all of the nitrate can be replaced by ammonium sulphate, for there is a real function to be served in fertilizers as elsewhere by the nitrate nitrogen which is not so well served by ammonia nitrogen. Nevertheless it is time to take account of stock and determine whether we are, to the maximum practical extent, using ammonia nitrogen for the replacement of nitrate nitrogen. If we are not, then it would be better to use some of this domestic production of ammonium sulphate and import somewhat less of Chilean nitrate for this purpose.

The Inevitable Economic Reaction

THOSE who have studied internal conditions in Germany have for some time prophesied that it would be wholly impossible to continue there much longer upon the system of subsidizing labor and industry by government budgets. Apparently the reaction from that false economic system is coming now. In any event, certain evidence which is accumulating tends to show that a new basis of industrial relation with Germany will develop within the next few weeks, or at the longest within the next few months.

Industrial costs depend largely upon the cost to the manufacturer of money, men and material. Definite information from German sources indicates that forced loans to the government are tending radically to reduce existing reserves and to enhance money costs to industry. Freight rates advanced about 33 per cent on Feb. 1, and the tax upon coal was increased to 40 per cent at the same date, so it is reported. The wage index of the *Frankfurter-Zeitung* shows increase from July, 1921, to January, 1922, of surprising percentages for labor in various industries. Some of those which are quoted from that source are: Chemical industries, 46 per cent increase; metallurgical industry, 78; shoe and leather industry, 50; woodworking, 60; building, 85; foodstuffs industry, 67.

The internal purchasing power of the mark is quoted as having decreased from 5.35 in January, 1920, to 1.76 in October, 1921. The "all-commodity" index of wholesale prices in German marks stood at 3,814 on Feb. 5, 1922, as compared with 3,467 in the preceding month, 3,233 in December, 1921, 1,484 a year ago and 100 in the middle of 1914. This decrease in purchasing power of the mark for domestic transactions is quite believable when one learns of the decree that was to take effect Feb. 16, that bread should cost 75 per cent more after that date than before it. It is not surprising, in view of these facts and the multitude of others like them, that the wage problems of German industries are by no means easily solved.

Germany tried a system in industry quite as fallacious in its economic groundwork as the Soviet economics of Russia. It was reasoned that by large units of industry such efficiency could be gained that the government might properly subsidize the formation of such industry and might by indirection keep the nominal wage and the market price of commodities below the level which normal influences of trade would have caused them to reach. It has been amply demonstrated, however, that the government cannot thus long subsidize business. The budget of the government by any such system becomes so badly unbalanced as soon to be unstable; and with the removal of the subsidy the readjustment which follows is likely to be much more disastrous than the normal and gradual adjustment that results in consequence of unrestricted movement of wage and price levels.

American industry, which must inevitably in many lines compete with German production, can find some measure of comfort in these tendencies. But it is too much to hope that these economic laws will altogether do away with the difference in costs in Germany and in this country. To assume such a result as that is to assume that the German nation is capable of providing for itself as high a standard of living for its working classes as American conditions have provided for the American wage earner.

Quantitative Economics And Invention

ONE of the slogans during the war was: "Produce more, consume less." That was quantitative economics. Our production and consumption had been approximately equal, but to find the things necessary for prosecuting war it was necessary that total production be increased and consumption, apart from the prosecution of war, be decreased. This relatively new science of quantitative economics promises to be interesting, which the old science of political economy was not. It is a science made possible by the fact that we now have much statistical matter measuring the industrial activity of the country, when in the old days we did not have such information.

One of the applications of quantitative economics is to determine whether we can do things we are trying to do or hope to do. There is the application to this question of the "living standard" which the labor leaders have been insisting on. In this department of CHEMICAL & METALLURGICAL ENGINEERING of Dec. 14, 1921, reference was made to the very interesting findings of the National Bureau of Economic Research, showing the national income for a period of years, expressed in dollars, converted into income per capita and adjusted to the 1913 dollar, whereby the income was expressed in its commodity purchasing power. This showed that on an average the individual income would purchase but little more than before the war, hence a raising of the "living standard" of any large number of people was impossible.

Another application of quantitative economics is to the growth of individual industries. Many industries have grown in the past half century at remarkably great rates, showing practically a geometrical ratio of progression. For instance, for a long time the production of pig iron substantially doubled every 10 years, while the freight ton-mileage of the railroads doubled every 12 years. For a time the production of coal increased at a more rapid rate still. The production and use of passenger automobiles, pleasure vehicles, increased very rapidly for a time. Men interested particularly in any one industry wish to see it grow and continue to grow, but quantitative economics informs us that everything cannot grow rapidly unless there are new developments to make it possible. Men cannot be taken from iron ore mines to operate railroad trains, and from railroad trains to make automobiles and from automobile factories to dig coal.

Quantitative economics shows that as a nation we cannot take out more than we put in, yet that is what we want to do. The only way out is to produce more per capita, and that means inventions. Since 1913 inventions along this line have been much less important than formerly.

We are looking forward to a great improvement in industrial conditions in the next few years, but we cannot compass that simply by doubling up on everything. Undoubtedly a great many men could be found whose idea is that the industry in which they are particularly interested should, as a new normal, operate at one-half greater pace than in 1913. Obviously that cannot be done without improvements, without a corresponding increase in efficiency. We cannot have 50 per cent more men engaged in mining coal, consuming coal, moving freight, producing iron, consuming iron, and so on all along the line. The individual workers must produce more, then they can consume more.

Readers' Views and Comments

On the Heat-Treatment of Aluminum Bronze

To the Editor of Chemical & Metallurgical Engineering

SIR:—A. A. Blue's paper "On the Heat-Treatment of Aluminum Bronze" in your issue of Dec. 7, 1921, gives a good introduction to the subject. Unfortunately, he ceased his own efforts to heat-treat and test these interesting alloys before be succeeded in obtaining satisfactory results. As he admits that the results given in Table IV were obtained by an inferior method of testing and in part on unsound bars, it would seem that the paper would have been of more value and less misleading had this table been omitted. However, it has some value in pointing out the reason for the author's astonishing conclusion that "heat-treatment produces little or no effect on yield point," for when a bar of this alloy containing 10.39 per cent aluminum is quenched in water from 1,780 deg. F., and then gives 9 per cent elongation in a tensile test, it is positive proof that the heating or quenching operation was improperly performed. A proper quenching of this material would lower the elongation to not over 2 per cent at the maximum, and if not properly quenched, the yield point cannot be expected to be raised either in the quenched or in the quenched-and-tempered bars.

The present writer had been all through this stage of the game with aluminum bronze before he finally learned the various causes of poor results and how to avoid them. It is a simple matter to do some hasty work on almost any material, getting poor results, and then to write a paper about them condemning the material.

It is entirely possible to obtain strengths of 100,000 lb. per sq.in. even with cast aluminum bronze of proper composition, properly treated, in spite of Mr. Blue's failure to reach this figure. The writer has obtained this result, not merely from one test, but from an average of several tests of different heats. All conditions must be right, of course, to reach this figure in a casting, or some little defect will creep in somewhere and lower the result, but with forged material it should be a simpler proposition. It is also possible to double the yield point and proportional limit of 10 per cent aluminum bronze by proper heat-treatment, as the writer knows from personal experience with numerous tests over a period of years, some of the tests having been checked and corroborated by the Bureau of Standards. Such treatment results in elongations between 8 and 15 per cent and also gives a decided increase in tensile strength.

The conclusion that aluminum bronze is difficult to handle in the foundry is entirely correct, though the bearing of the paper on this point is hard to find. Still there are foundries where this alloy can be produced consistently.

One other point is open to criticism in this paper, and that is the author's indefinite use of the term "annealing," which he confuses with tempering or drawing after quenching. The structures shown by Figs. 12, 13 and 14, for instance, are evidently of quenched and tempered alloys, and could scarcely be the result of simple annealing, as might be understood from the title. There is, moreover, no mention in the paper of the important fact that simple annealing of this cast alloy, unquenched, increases its hardness slightly and spoils its tensile properties, decreasing both strength and ductility.

GEORGE F. COMSTOCK,
Niagara Falls, N. Y. Metallurgical Engineer.

To the Editor of Chemical & Metallurgical Engineering

SIR:—In the article written by A. A. Blue, "On Heat-Treatment of Aluminum Bronze," and published in your issue of Dec. 7, 1921, there are a few points and conclusions with which no one who knows aluminum bronze can agree.

The writer agrees with Mr. Blue's conclusion 2, that heat-treatment produces marked and consistent changes in Brinell and scleroscope hardness, but conclusion 3 is the opposite of what my experience and that of others show.

In Table II Mr. Blue tabulates hardness tests after various heat-treatments which are not readily comparable on account of variation in composition. Variation of 0.5 per cent Al is not tolerable in this region of Al-Cu alloys for comparative tests.

Table IV of his article gives puzzling results of physical tests after various heat-treatments. Most if not all of the figures in this table do not check with those obtained by other investigators—for instance, with results of H. C. H. Carpenter and C. A. Edwards. They are not consistent—e.g., test 158 gives tensile strength 61,000, yield point 19,000 and elongation 20.5 per cent for material as cast, and for the same material after quenching, test 161 reports tensile strength 69,500, yield point 20,000 and elongation 3 per cent.

Another anomaly can be seen on page 1048, where Mr. Blue gives the following properties for a bar quenched from 1,700 deg. F., drawn at 1,000 deg. F. and cooled in lime: Tensile strength 79,480 to 81,495, yield point 20,000 to 32,500 and elongation 20 to 22.5 per cent. From numerous tests I have found it impossible to obtain 20 per cent elongation by drawing aluminum bronze of this composition at this low temperature; 2 to 5 per cent is all that can be expected and the yield point would be correspondingly higher, 50,000 to 60,000 lb. per sq.in.

The theory of heat-treatment of aluminum bronze is simply this: By heating to proper temperature all of the alpha phase is absorbed; by quenching, this condition is retained, resulting in high tensile strength, yield point and hardness, and low elongation. By drawing at proper temperature above the transformation point, a desired amount of alpha phase is restored, resulting in an alloy of lower tensile strength, yield point and hardness than the quenched alloy, but higher in elongation. The higher the drawing temperature the lower the tensile strength, yield point and hardness, and the higher the elongation. The proper temperature for quenching is evident even from Mr. Blue's photomicrographs, Figs. 15 to 20. The proper temperature for drawing must be always above the transformation point, and the temperature of 1,000 deg. F. used by Mr. Blue cannot result in restoring any alpha phase and increasing the ductility; on the contrary, it may cause decomposition of beta phase into eutectoid, resulting in a still harder alloy. This increase in brittleness and hardness at low draws was noticed

by Mr. Blue is his impact, compression and hardness tests. Therefore, obtaining 20 per cent elongation after quenching from 1,700 deg. F. and cooling slowly from 1,000 deg. F., is an anomaly which alone would tell the investigator not to be satisfied with his tests.

In our experience there has been no exception to the fact that sound aluminum bronze of 90:10, or 89:10:1 (Fe) responds to the proper heat-treatment, and our representative figures for aluminum bronze as cast, and after heat-treatment, are as follows:

	Tensile Strength	Yield Point	Elongation	Brinell
As cast.....	65,000 to 70,000	25,000 to 30,000	20 to 25	90 to 100
Quenched.....	85,000 to 95,000	60,000 to 70,000	1 to 2	220 to 240
Quenched and drawn	80,000 to 93,000	50,000 to 60,000	4 to 10	187 to 200

From these figures it is evident that the heat-treatment does produce a considerable change in tensile strength and yield point, as well as in hardness and elongation. It is also evident that Brinell hardness and tensile strength correlate, which is not in accordance with Mr. Blue's findings. In our practice of heat-treatment of castings we use Brinell test for checking the heat-treatment and for judging the tensile strength and elongation of the material after heat-treatment. This practice, of course, was preceded by exhaustive tests proving that Brinell hardness and the other physical properties correlate sufficiently. Here it may be mentioned also that the results obtained on aluminum bronze test-bars cast to shape (1 in. diameter), and test-bars cut out of a casting, give approximately the same result —unlike other bronzes.

Mr. Blue's forging experiments are also insufficient and the forging is followed by erroneous method of heat-treatment. But even those, as well as our own experiments, indicate that by forging it is possible to combine a high tensile strength with high elongation. Mr. Blue states, "The results show some improvement in tensile properties, but an increase in brittleness in the heat-treated specimens." But this increase in brittleness is due not to forging, but to the faulty heat-treatment—viz., drawing at 1,000 deg. F. and cooling in lime. This treatment will result in brittle metal independent from previous treatment, and this Mr. Blue could have seen from the equilibrium diagram which he included in his paper.

BRUNO WOYSKI,
Chief Metallurgist.
Lumen Bearing Co.,
Buffalo, N. Y.

To the Editor of Chemical & Metallurgical Engineering

SIR:—In reply to criticisms by Messrs. Comstock and Woyski, I would say in the first place, the material used in the majority of the tests recited in this paper, including all of the tensile, impact and compression tests, was purchased from the Lumen Bearing Co. and a number of actual castings which were tested and failed in practical tests were treated by the Lumen Bearing Co. and another lot by Mr. Comstock personally. These castings behaved in the same manner as those treated in our furnaces and failed at the same loads. In order to indicate that these tests were not unreasonable, another type of bronze was later obtained which has stood up satisfactorily under the same tests.

Concerning the criticisms of testing methods, it may be mentioned that all of the tensile, impact and compression tests were carried out in the laboratory of the Carnegie Institute of Technology, under the personal supervision of Prof. F. M. McCollough, the head of the department, which leaves no doubt as to the fact that the figures reported represent the properties of the material tested.

It was the purpose of the paper in question, as pointed out in the first paragraph, to be of value to those interested "in what results they may expect to obtain from it under actual conditions of its everyday practical manufacture and treatment." Without, therefore, going into a detailed discussion of metallurgical considerations involved, the following should be mentioned:

In the last paragraph of Mr. Comstock's letter, unwarranted liberty has been taken with the original paper as regards Figs. 12, 13 and 14. The structures shown in these photographs were obtained, as noted in the caption attached, by "annealing," and not by "tempering or drawing after quenching," as Mr. Comstock supposes. The samples were heated to the temperatures indicated, and permitted to cool as noted, no quenching whatever being involved. Included in the same paragraph, Mr. Comstock states that no mention has been made of "the important fact that simple annealing of this cast alloy, unquenched, increases its hardness slightly and spoils its tensile properties." As a matter of fact, Figs. 22 and 23 show that simple annealing *decreased* the hardness, both Brinell and scleroscope, which was brought out in the text on page 1045, last paragraph.

Referring to Mr. Woyski's communication, the chief point of this criticism hinges upon the heat-treatments given, especially exception being taken to the use of a drawing temperature of 1,000 deg. F. We understood that a number of the castings treated by Mr. Comstock to make them suitable for our purposes were drawn back to this same temperature—i.e., 1,000 deg. F. Our understanding is that this also applies to similar castings treated and furnished by Mr. Woyski's company.

In conclusion, the matter is, of course, simply the old one of buyer and seller. We are interested not in what *may possibly* be done with aluminum bronze, but in what *can always* be done with it day after day, so that we may rely upon it in insuring our own customers in using our product. It failed to meet these requirements, first, when tried out in actual service tests; second, in the tests described in the paper in question, and, third, after the personal efforts of other metallurgists to make it do so. In view of the large amount of money and time expended in these tests, covering nearly a year's time, the results were distinctly disappointing. Therefore we were forced to the conclusion, as mentioned, that a number of the published figures concerning this material were unreliable as an indication of what it would do in a practical way. We know of no reason for changing this conclusion. Aluminum bronze has many novel features, and is an interesting material in the laboratory, which has, no doubt, led its enthusiastic adherents to make claims for it which actual practice will hardly justify. On the other hand, it possesses many features of technical importance, prominent among which should be mentioned its excellent bearing qualities. In fact, we use it regularly in a number of parts where only moderate stresses are involved, with complete satisfaction. However, for heavy duty work, as mentioned above, we have found another bronze to be more satisfactory and to be in better accord with the figures claimed for it, the following being an example: Tensile strength, 101,990 lb.; yield point, 62,250 lb.; 14.5 per cent elongation; 17.4 per cent contraction.

Pittsburgh, Pa.

The Soldier Bonus

To the Editor of Chemical & Metallurgical Engineering

SIR:—Just a word about the soldier bonus to describe how the situation strikes one of that great mass of ex-soldiers who have so far said nothing but have quietly watched the agitation for and against.

Visualize the following, if you can:

The fair daughter of a corpulent, well-dressed individual, radiating prosperity, has just been rescued from a watery grave by the noble efforts of one of the corpulent gentleman's workmen at the risk of his life. The corpulent individual is moved to tears, and is loud in his praise of the hero. But wait! The corpulent gentleman, having given profuse thanks, now attempts to depart. The hero, however, demands a reward. The face of the corpulent individual changes immediately. No, he is too poor; it would ruin him; must he not buy his daughter more clothes for the ones that are spoiled?

Picture now the corpulent individual hounded by the hero for his gratuity. Is it not laughable, ridiculous, even painful to consider? Both have lost the last shred of the spectators' respect. From the sublime to the ridiculous!

It is difficult to conceive of anyone consoling either of these figures. However, of the two I must admit that my sympathies are decidedly with the unsatisfied hero.

To begin with, it was certainly bad taste for the "hero" to demand a reward, but was it not worse taste, on the business man's part, not to offer one?

The whole situation is disgusting in the extreme in that it has not only to a large extent debased the gratitude due ex-soldiers, but has shown American business in the light that European nations have viewed it for years, but to which true Americans have long tried to blind themselves.

Down with honor! Up with the DOLLAR $!

Philadelphia, Pa. N. F. WILSON, JR.

SAYS BUSINESS WAS NOT IN THE TRENCHES

To the Editor of Chemical & Metallurgical Engineering

SIR:—The reason our government is not more representative is because most of us are not interested enough to take the trouble to raise our voices in defense of legislation we favor or to protest when we are not in favor.

To be sure, business does not want the soldier bonus, but business was not in the trenches or the camps. I was not sent overseas and therefore do not feel entitled to the bonus. No sum of money would be enough to be considered "in full for services rendered." The men who helped build Hog Island were not paid the same wages as the men who "fought their way through the Argonne."

It is not for the members of the American Legion as such to make suggestions to solve this problem, for the country did not ask the soldiers how to carry on the war; it asked them only to fight. RICHARD RIMBACH.

Butler, Pa.

SAY EX-SERVICE MAN ASKS ONLY JUSTICE

To the Editor of Chemical & Metallurgical Engineering

SIR:—As readers of your magazine, we wish to take exception to certain statements made with reference to the soldier bonus. We do not believe that we are in the minority in supporting this measure, as public sentiment, wherever taken, has proved that the compensation of ex-service men is very popular. Ohio recently approved a state bonus by a 3½ to 1 vote. Several of the chambers of commerce, notably the Cleveland Chamber of Commerce, have approved the measure.

Speaking as one "having experience, if not authority," you mention that five members of your staff are opposed to the bonus. After your first editorial, it is doubtful if they would come out openly in favor of the measure and still hope to retain their positions.

The principal argument, and one which we have not seen satisfactorily answered, is that compensation was paid to those who lost on war contracts, to the railroads and to civilian employees of the government. The ex-service man, who lost not only money but also the advancement which came to those who remained in civil life, asks only for justice. JAMES C. WEBSTER,
V. M. BURROWS,
EDMUND WENDEL.

Cleveland, Ohio.

Colloidal State in Metals and Alloys

To the Editor of Chemical & Metallurgical Engineering

SIR:—I have read with much interest Mr. Alexander's contribution and should like to congratulate you upon the very interesting manner in which he is dealing with this subject. The matter is one of great industrial importance and while being much interested in the colloidal aspect which the author introduces, I suggest that, as regards the experimental evidence which he considers, he should be more precise, when considering the work of other investigators, in dissociating between facts discovered by them and hypotheses put forward in explanation. On page 120, second paragraph, the author states that Dr. Jeffries "has shown that with metals in general the cohesion of the amorphous phase equals that of the crystalline phase," etc. Much as I admire the work of Dr. Jeffries, it is a fact that he has not shown experimentally that the amorphous phase exists, neither has he shown any dissimilarity in the properties of the two phases. What Dr. Jeffries has done is simply to postulate, along with other thinkers, that the amorphous phase exists and then, by further hypotheses, to deduce a dissimilarity in the properties of the two phases.

I write this in no hypercritical spirit, but simply with the desire to emphasize that little progress can be made in our attempt to put this subject on a sound basis unless we do dissociate facts from theories. This particular aspect of matters becomes very important indeed when one contemplates the very important new facts concerning metals, particularly aluminum, brought out in a paper by Dr. H. C. H. Carpenter, F.R.S., and Miss Elam, given in July before the Royal Society in London. They have been able to make tensile test-pieces consisting of single crystals and to explore their properties to a considerable extent. This new evidence, in the writer's opinion, indicates that the amorphous theory, so ably handled by many of our metallurgists and physicists, must be reconsidered—at any rate, many of the minor hypotheses concerning the properties of crystals and amorphous films upon which the amorphous theory was based are now shown to be untenable.

This subject, as I have said above, is of great industrial importance, and it is to be hoped that the author and other investigators will not let the matter rest until we have actually provided sufficient data for a really satisfactory visualization of the mechanism and effect of cold work upon metals. W. H. HATFIELD.

Sheffield, England.

Midwinter Meeting American Institute of Mining and Metallurgical Engineers

Dr. Bancroft Presents the First Institute of Metals Lecture—Important Papers and Animated Discussions on Manufacture of Fine Steel—Quality of Steel in Its Relation to Subsequent Use Also Considered—Arthur S. Dwight the New President

IN ACCORDANCE with custom, the American Institute of Mining and Metallurgical Engineers met Feb. 20 at the Engineering Societies Building in New York City for the midwinter meeting. Technical sessions occupied the mornings and afternoons of the first three days of the week, simultaneous meetings of various sections being the rule rather than the exception. Thursday was spent in a very enjoyable, well-directed and all too brief tour of various industrial plants at Harrison, Carteret, Chrome and Perth Amboy, N. J.

Arthur S. Dwight, widely known throughout the Rocky Mountain region as a lead metallurgist and in late years as the "man behind" a successful sintering machine, made his début as president of the Institute at the banquet held Wednesday evening, Feb. 22. As a measure of the interest manifested at all the meetings, it may be stated that the banquet attendance fell but a little short of the record number. Other social functions —smoker, dances, receptions and excursions—filled the time of the members to overflowing.

Institute of Metals Lecture

To our readers, perhaps the most interesting event was Dr. Wilder D. Bancroft's lecture on "Colloid Chemistry and Metallurgy." It was the first of a proposed series of annual lectures. Judging from the attendance and the enthusiasm displayed, the directors of the Institute of Metals Section have embarked upon a program which will have important and far-reaching effects.

Critical Commentary on Amorphous Theory

Defining colloid chemistry as the chemistry of bubbles, drops, grains, filaments and films, Dr. Bancroft immediately passed to a critical examination of Beilby's theory of films of amorphous metal. In fact, throughout the discourse the lecturer took the attitude of a skeptic and pointed out that many of the things of which metallurgists and metallographers talk rather glibly are things which may have been postulated to account for certain experimental results, and with actual proof either non-existent or at best very meager. He took the view that the advocates of Beilby's amorphous metal hypothesis have made an extraordinarily good case with no facts behind them, while the dissenters have never challenged their opponents' premises. Even though it may be true that direct proof of amorphous metal at crystalline boundaries may never be had, there is no reason for accepting it without question in view of the fact that amorphous metal is difficult to form, and being an unstable phase, it will easily revert to the crystalline and stable condition.

Beilby advanced his theory to explain the strengthening of metal by cold-work, but high strength electrolytic copper can be deposited with high current density, and it certainly is not amorphous. Beilby's reasoning seems to be this: "Glass is amorphous and brittle; therefore an amorphous material is always harder and more brittle than the corresponding crystalline aggregate," of course an absolute *non sequitur*. Cold-work is supposed to produce fragments of crystals too small to be crystals. However, it has been found long ago that electroplated copper 3 to 5 millionths of a millimeter thick has the properties of massive copper, and Dr. Bancroft doubts whether cold-work could produce fragments of this size. In fact, the lecturer feels that the properties ascribed to amorphous metal are more likely to be properties of an aggregate of extremely fine crystals.

As an instance of the metallographer's tendency to take things for granted Dr. Bancroft cited the belief in two diagrams for steel. The conclusion that cementite is the metastable state at room temperature is derived from bad reasoning from inadequate examination. The evidence is this: (*a*) Graphite is the stable phase above 1,000 deg. C.; (*b*) quenched gamma iron containing carbon produces graphite on annealing. Now (*a*) says nothing about the stable phase below 1,000 deg. C.; and as to (*b*), it is possible that graphite is intermediate to the final stable compound Fe_3C.

Solid Solutions

Jeffries and Archer's writings on hardening by slip interference appeal to Dr. Bancroft as the "best formulation of the causes of hardness we have ever had" and a distinct step forward. He expressed himself as being personally much delighted by their explanation of the hardening of duralumin and martensite. They were also on sound ground in insisting that Fe_3C does not dissolve in austenite as such—it is not necessary that it should. Bearing on this point, it should be remembered that the copper-tin equilibrium diagram indicates a series of solid solutions passing through the compound Cu_3Sn, and it is orthodox to say that some of these solutions contain the compound. However, it is possible to produce the compound Cu_3Sn, and it will not go into solution in bronzes; are there two different kinds of Cu_3Sn? As a matter of fact, modern metallographists play fast and loose with compounds and solutions, postulating them everywhere. There are six of them already in brass, and maybe there will be more if we do not own up to our ignorance of the essential structure of many things we see under the microscope.

However, it is very necessary that we should know more about the state of aggregation of alloy components. Take the familiar case of thoria and tungsten. If a fine thoria powder be shaken up with coarser tungsten particles, the fines coat the grains rather than accumulate in the voids and a composite briquet is therefore a poor conductor. Alloys between two metals, *A* a conductor and *B* a non-conductor, will naturally have electrical characteristics depending upon whether *A* is dispersed

in *B*, *B* is dispersed in *A*, or whether both metals are continuous and interlace. Yet discussions of conductivity of a series seldom mention this essential point.

State of aggregation of inclusions in steel is apparently of great importance to its endurance under alternating stress. Now is this generally true for other alloys? An increased endurance in metal would be a tremendous advance in metallurgy, and it therefore behooves us to investigate whether it is possible to make clean metal, and whether it is possible to make it commercially.

Corrosion Resistance Due to Surface Films

Colloid chemistry should throw much light upon the corrosion riddle. It is doubtless a hopeless task to produce an absolutely non-corrodible metal—even platinum is probably covered with an oxide—but it is necessary to make metals which corrode only to a limited extent. From its chemical behavior, metallic aluminum would be predicted to be perfectly useless, yet when exposed to ordinary service conditions it becomes covered with a coherent protective film which effectively slows down subsequent action. Nickel also forms a protective film; iron does not. What is the reason for the difference? Measurements of electromotive force are not very informing, since they give only the "tendency" for corrosion and since actual occurrence is the essential point. Thus all the bronzes have e.m.f.'s which lie between tin and copper and have a "tendency to corrode" more than copper but less than tin. As a matter of fact, if a certain group of brittle bronzes, containing 40 to 80 per cent tin, are made anodic in salt solutions, they stand up in a surprising manner, simply and solely because they immediately build up a film of stannic oxide which is coherent and protective. If we knew more about this film we might be able to put metallic tin into such a condition that it, too, would acquire it, whereupon a great boon would be conferred upon the canning industry. Similar studies would tell why copper-bearing steel corrodes less than copper-free steel in the atmosphere, but more rapidly in ground waters.

Electrometallurgy and colloid chemistry have many points of contact. If the electrolyte contains some substance which is absorbed by the metallic deposit, crystals of the latter cannot grow. For this reason, glue has made possible electrolytic lead refining; without glue, the lead is deposited as lovely but useless lead crystals; with it, a dense coherent deposit occurs. Similarly in electroplating. A burnished copper deposit can be taken directly from the tank; unfortunately it costs a little more than to do it the old way. Again, colloidal solutions, or, rather, peptized suspensions, are good things to avoid in electrometallurgy. As instances, the operating temperatures in sodium or aluminum furnaces must be above the melting point of the metal, yet below the temperature where the metal is peptized in the bath, a range which is extremely narrow. If the bath overheats, the metal "fogs," goes to the anode and burns.

Fine Steel From the Acid Open-Hearth

A series of very important papers relating to quality metal were presented before the Iron and Steel Section meetings, drawing forth an animated discussion skillfully directed by the chairman, Mr. Stoughton. Principal among these was "Acid Open-Hearth Process for Manufacture of Gun Steels and Fine Steels," by W. P. Barba and Henry M. Howe, the long-awaited report of work done during the war by the committee on steel ingots, National Research Council.

In summarizing the paper, Colonel Barba said that while the paper is complete in its discussion of principles, many of the almost numberless details of application have not been mentioned. Indeed, many of these details could with extreme difficulty be described—they must be acquired by personal attendance and constant observation on the furnace and pouring platforms. Roughly, half the paper is given over to a description of an adequate furnace and its manipulation, and the remainder to correct pouring practice. It is of first importance to have an adequate furnace—a furnace which will produce and withstand the high temperatures necessary for the reactions going on in the bath. Given this essential implement, one should select the raw materials carefully (having in view the uses for the final product), he should melt hot, refine hot and pour cold into ingots of proper size and shape (again having in view the uses to which the final product is to be put).

If the word "dirt" be used to denote various impurities and inclusions in steel which adversely affect quality steel, "dirt" occurs in two forms—"chemical dirt," the uniformly distributed reaction products, and "mechanical dirt," the occasional and fortuitous particles of foreign materials acquired from the containers. It is very easy to distinguish between these two kinds of dirt. Many American steelmakers have the necessary knowledge, skill and will to reduce all dirt to a minimum, but these same producers must educate the American purchaser to the point where he will appreciate the actual economy in paying the necessary high price for clean steel for special uses. Many consumers do not know that their rejections on final inspection would cease to worry them if they started with the proper metal. Others who want especially good steel for certain purposes do not know it can be had.

Pouring Practice

A visiting English metallurgist, Harry Brearley, was given a warm welcome when he commented upon this paper—especially as regards pouring practice. He emphasized that the temperature in the mold, rather than the temperature in the ladle, was that which was responsible for crystal growth and the physical excellence of the ingot. Thus it is easily possible to "pour cold" with a thin slow stream of very hot metal. Furthermore, it is easiest to judge the temperature by observing the top surface of the metal rising in the mold: it should freeze into a distinct crust and appear like a broken film of cream floating on milk. In Mr. Brearley's opinion, one of the important advantages of bottom casting was the ease with which conditions in the mold could be observed. Somewhat counteracting this was the undoubted fact that bottom-cast ingots ordinarily contained more dirt picked up from the runners. His firm minimized this by extreme care in preparation of molds and by cleaning them with a powerful vacuum cleaner immediately before pouring.

Another advantage of bottom-casting is that the method permits the mold to shape the ingot. When top-casting, the impact of the stream of hot metal always produces more or less commotion in the upper surface. If the flow of metal were stopped at any time and the top surface be examined, it would be found that there would be a thin fringe of metal ("swirl envelope") heaped up and chilled against the side of the mold. This continually formed swirl envelope is the real mold. It is always badly oxidized; the carbon in the advanc-

ing hot steel reduces the oxide partially, forming small quantities of gas bubbles close to the surface. These are later filled with rather impure mother liquor, squeezed into them by the solidifying primary crystals of purer metal, and can be strikingly shown by a sulphur print of a split ingot.

Flakes and Woody Fracture of Nickel Steel

Since the paper by Barba and Howe described the correct manufacture of nickel steel, Haakon Styri recalled the war-time trouble with flakes. In some plants it was observed that their first heats, made by addition of shot nickel shortly before tapping, were accepted. Only when they began using nickel scrap did flakes appear, and one explanation of the cause of flakes was that nickel steel was so much more viscous than carbon steel that its refinement was correspondingly difficult. Colonel Barba pointed out, however, that if the temperature of the furnace in the refining stage is as high as it should be, carbon steel and nickel steel act exactly alike; any difference of viscosity at this temperature is unworthy of mention. In his experience it was entirely immaterial when and how nickel was added—economy and convenience were the only considerations; indeed, for many years most acceptable gun steels were made by adding nickel oxide to the charge. Brearley also denied that nickel steel was necessarily full of slag inclusions, despite wide belief in the myth. To be clean it must be made right. Furthermore, its inherent toughness caused the inclusions which were contained to become very evident in a fracture. It ought to be axiomatic that an inclusion is a discontinuity in steel, and that discontinuities do not show until the metal is deformed. A metal which is brittle, for instance, will show a sharp break despite an actual fibrous or laminated structure. If wrought iron could be made brittle, it doubtless would lose its characteristic fracture. On the other hand, nickel steel, like normal wrought iron, is so tough that it must deform very considerably before fracture, and any discontinuities are sure to be sought out and much magnified into the appearance of fibers before ultimate rupture.

When introducing his paper on "Effect of Sulphur and Oxides in Ordnance Steel" W. J. Priestley of the U. S. Naval Ordnance Plant wished to distinguish between true flakes occurring in nickel steel made in the electric furnace and similar defects in open-hearth metal. The latter always contain slag inclusions, while a true flake has none. In his experience the microscope can indicate whether a gun steel is likely to develop woody fractures; forged open-hearth steels containing perhaps 0.04 per cent sulphur when examined in longitudinal section will show small round inclusions and much larger particles, elongated and drawn out in forging. It will also show woody fracture and lower ductility (elongation 18 per cent, contraction 40 per cent) when tested tangentially. Electric-furnace steels, properly refined under a carbide slag and with sulphur reduced below 0.015 per cent, show only the tiny round inclusions, tangential specimens will break with silky fracture and show higher ductility (elongation 24 per cent; contraction 53 per cent), results which would be looked upon as very remarkable indeed 10 years ago. Such steels, however, will develop true flakes if cast too rapidly at too high a temperature, chilled below a certain point in the mold, or even cooled too far in forging. Minute radial cracks will then appear near the center of the ingot or forging.

Degree of Reduction in Ingots

Ordnance makers at the outbreak of the war were still working to specifications framed 30 years ago when all heavy forgings were shaped under the hammer. On account of the somewhat superficial effect of a quick blow a reduction of 4 to 1 was required for gun tubes. Meantime the hydraulic press was introduced, so during the war the specification was modified to allow only 2½ to 1 reduction. Colonel Barba expressed the opinion that a ratio of 1¾ to 1 would be quite safe for 6-in. forgings made of best steel and with heavy presses; penetrative effect was not well known, so a greater reduction would be justified for larger pieces.

Degree of reduction has a considerable bearing upon the quality of the finished piece, and correspondingly upon the physical properties of test-bars. There are really three main dimensions to a forging; in a gun tube they might be called longitudinal, tangential and transverse to the direction of extension by forging. Tangential tests are most useful in studying quality of gun tubes, first, because they parallel service stresses, and second, because they best show defects and foreign inclusions. However, Priestley remarked that a tangential test-bar from a tube which had been reduced 7 to 1 would give a percentage contraction little over half that from the same steel reduced only 2½ to 1. To avoid this weakness, the forging should apparently be just sufficient to allow ingot structure to be broken up by subsequent heat-treatment, and yet not so great as to range the inclusions along definite planes. Thus it is that while commercial consideration might dictate that big ingots be used to make small articles, it was not always desirable from a metallurgical standpoint. One might infer from Colonel Barba's remarks, however, that heavy reduction of not too clean steel was most desirable for armor plate, since he observed that he would be suspicious of a plate if a bar cut from face to back would give more than 1 or 2 per cent elongation. He said that to be tough enough to keep shots out, a plate had to be laminated parallel to its face. Priestley, however, observed that there was room for difference of opinion on that point; armor plate made from deoxidized and desulphurized electric furnace steel would possess considerable ductility if tested transversely (from face to back). Such plate, when pierced by a shell, opened at one spot and segments curled back like an orange peel. If plates such as Colonel Barba described were penetrated, the shell seemed to punch out a clean button.

Test for Dirt in Steel

Such considerations led Brearley to propose a test for dirt in steel based upon the ratio of impact strength of longitudinal and transverse bars. If, for instance, an ingot be rolled under controlled conditions into a 5 x 1-in. bar and test-specimens be cut at varying angles to the direction of rolling, it would be noted that the tensile strength was substantially the same in all directions. Figures for ductility were also constant until the angle passed 40 deg., when they would show a drop. Notched bar impact, however, would be highest in a bar cut in a longitudinal direction, but progressively less as the angle increased up to 90. In his opinion the two impact values (at 0 deg. and at 90 deg.) never could be equal; in most commercial steels the ratio is not over one-tenth. However, in fine steel, such as for ball races, it should be at least one-half. He recommended this ratio as a measure of "dirt in steel."

Industrial Research and Patents

A Competent Patent Department Can Aid the Research Laboratory in Examinations Into the Literature and State of the Art, in Charting Lines of Inquiry Not Blocked by Patent Barriers, and in Protecting Embryonic Ideas Pending Their Commercial Development

By CLAYTON L. JENKS
Patent Attorney, Norton Company, Worcester, Mass.

BUSINESS MEN are ordinarily quick to recognize a new order, but have they grasped the present opportunities offered by research? How many managers of manufacturing corporations know the value of systematic investigations along commercial lines? How many have definite plans for experimental development?

The Factory Laboratory

The man down in the plant as a rule must lower costs and handle the everyday problems of keeping the plant going. What he most wants to hear is the smooth hum of well-oiled machinery, to know that his work is being done on time and well. The very nature of his work tends to make him conservative; but it also shortens his perspective. He perhaps recalls some earlier financial loss due to misplaced confidence in an invention alleged to be valuable and looks suspiciously upon all inventors and researchers.

Nevertheless, because of the difficulties of maintaining quality and standards in the face of growing competition, and knowing somewhat of the investigations of the more progressive companies, the successful factory manager ultimately establishes an engineering department for developing new machinery and later a laboratory for handling the more scientific problems of the factory. Since the main problems in the factory manager's mind are cost, speed of production, quality and works control, a laboratory developed under factory supervision and representing the gradual outgrowth of the necessity for scientific plant control will reflect mainly the practical side of the work in equipment and personnel. The inventing business is viewed in the light of money returns, and the laboratory men become limited in their activities largely to the problems of correcting factory troubles. Spare time only is spent on research.

The works problems may be of no mean order and require the services of highly technical students, as well as skilled artisans. These laboratory men occasionally hit upon new ideas in the course of their investigations, but for lack of time and resources must carry on their experiments according to some haphazard method. Such investigations must be sandwiched in with routine tasks, and soon the edge wears off of the workers' enthusiasm. Ever-insistent foremen waiting to be shown how to correct their errors keep the research notebook in the desk drawer and the problem is laid aside for less crowded days. Still, if lucky, something good may be developed and the state of the art advanced to the glory of the haphazard inventor and the welfare of his employer, if the half-thought-out invention survives competition and the tests of time.

But such sporadic attempts are not research. Thoroughbred racers cannot do the work of draft horses, nor do the latter win many races. Research must be conducted by research men in proper surroundings and with research equipment. Patent the basic ideas of such laboratory work? It may never be thought of!

The Old-Fashioned Engineering Department

In the engineering department, the chief engineer dominates the inventing business. He is an inventor, made conservative by years of hard knocks. His new machines are eagerly sought, for his work is good. What are his methods? Being an inventor, he is possibly jealous of his pet schemes, intolerant of others' ideas. Surrounding him are embryonic mechanical engineers fresh from college or enthusiastic draftsmen, full of ideas, imaginative, perhaps intolerant too of the "old man's" conservatism. They suggest inventions to the chief, which as originally sketched out are probably poorly designed and not commercially feasible. With a hasty glance over the drawings, the chief turns them down. After a number of such rebuffs the youthful inventor concludes that imagination and vision are unwanted. Yet within some poorly thought out scheme may have been a germ of value, capable of development by the older and more practical engineer; but the scheme is dropped and forgotten. Years later, the engineer, perhaps subconsciously recalling the old idea, reinvents it and finds it worthy of development. He builds his machine for the market and then finds it patented by a rival.

It is almost axiomatic in the patent business that if one man does not invent a certain improvement today, another will tomorrow. The different workers in an art read the same literature, see the same machines on the market and learn of the same requirements of the trade. Is it any wonder that they invent the same things? The man first to the Patent Office is likely to win the field.

When that young man's suggestion was offered, the chief engineer, disregarding the patent situation, refused the idea merely because it was *impractical as then clothed*. A preliminary patent search might have shown that the idea was unprotected by patents, that it in fact found the weak spot in a competitor's armor, that it provided a passage to the market free from patent dominance. A little experimental work, sometimes a mere "paper patent," would have reduced the idea to practice and saved a valuable monopoly.

The amount of property, the wealth of ideas lost by such old methods, is large. With the same organization, the same brains around him, that engineer, by judicially investigating the new ideas, experimenting and modifying, selecting the wheat from the chaff, could produce far greater results. His fairness would bring around him a group of loyal enthusiasts. He, the older practical man, would serve as a balance wheel, the others would furnish the fuel.

"Of what use are these theorizing dreamers, these impractical scientists?" says the practical shop man. That question has probably been asked since Adam and Newton observed the different phenomena connected with the apple. Such a business man would not understand how Kekule's benzene ring formula could be of any practical use, yet most dyemakers do. But the dreamers keep on theorizing in spite of ridicule; they need no defence. Not only will their contributions to science be remembered, but they are fundamental to our modern civilization with its luxuries and comforts.

It must be obvious that real commercial progress calls for systematic research effort, but how make it pay? The answer lies in the solution of the further question: Is the laboratory merely doing the necessary routine factory analyses, solving the problems of quality and production, occasionally hitting upon some new method or product, partly accidentally or because there is a temperamental man in the laboratory who cannot be held down, or is the laboratory working within a well-defined channel, studying its problems from theoretical aspects, and yet keeping practical minded, with its weather eye on the patent situation in every move?

Essentials of a Laboratory[1]

From the experiences of various large laboratories it may be concluded that the company management needs to do but four essential things: Decide upon a research policy, equip a laboratory, appoint a director and give him a definite yearly appropriation. Then—back the research with dollars and patience. The director should not be required to produce remunerative ideas at first, perhaps for several years. The value of his work is cumulative and will increase rapidly as time goes on. It is of absolute importance that the laboratory should be entirely dissociated from the factory departments, yet be kept posted on manufacturing activities. To insure these conditions the director of research should report only to the management and have complete control of his work and expenditures within the stipulated limitations. Above all, he should not have to explain beforehand how a given investigation may lead to commercial results. There is no surer way to kill inventive progress than by requiring such proof. In fact, purely theoretical research, with no practical goal in sight, often leads to the greatest achievements. The original workers with vacuum tubes or high-frequency electric currents surely did not realize the wonderful commercial possibilities in their theoretical studies.

The laboratory should be divided into two divisions: (*a*) for manufacturing control and (*b*) for science, and the men for the two branches carefully selected according to their leanings toward practical or theoretical problems. If the laboratory is housed apart and equipped with a complete manufacturing outfit, its tests may be conducted on a manufacturing scale where necessary without interfering with the production department, which ordinarily has no enthusiasm for the notions of "impractical dreamers."

It is generally impossible to staff a laboratory with a large number of geniuses, but one must obtain well-trained men who have a taste for research. They must be men of imagination, inventors, with enough enthusiasm to keep buoyed up under the criticisms of the shop men. It is also considered a fact that the yield per man increases with the number of men who can co-operate. Most problems are so large as to require the combined efforts of men who are specialized in different fields. Hence each man should be encouraged to be frank and helpful in analyzing his co-workers' problems and in giving the best of his own inventive ideas as suggestions for the others' use. A properly worked out system of awards and recognition will do away with the jealousy and secretiveness so frequently associated with the inventive mind.

Since only a small percentage of the investigations started are likely to be successful, the director should be capable of properly organizing his department and the work, and strive to reduce to a minimum the proportion of unsuccessful cases. Generally the deeper the investigation goes into fundamental facts the greater the chance for success. The choice of research work must be determined by the laboratory men's ideas, and not by the too practical considerations of the management, but of course such work should all fall within certain well-defined lines laid down by the directors of the company.

Interrelations of Patents and Research

Assuming that such a research laboratory has been organized, where is it likely to fail? Often in spending large effort, money and time on ideas already appropriated by others' patents.

Not understanding the nature of patents, with their repetitions, their fine shades of meaning and their ambiguities—all legal problems—many researchers ignore the patents and do not consult this remarkable collection of literature. Yet where could one find a better story of any particular art than in the U. S. Patent Office archives? Others perhaps think of patents as legal barriers tending to prevent research. A patent is a barrier, however, to but a small field. Obviously one of those million and a third U. S. patents cannot stop investigations.

Other laboratory men, like true Americans, naturally abhor monopolies and keenly feel that research should be open, co-operative and always in the interest of the progress of the sciences. Hence, while loyal to his company's welfare, such a man may instinctively object to his ideas being patented.

There are several reasons for taking out patents. From the point of view of the owners of the company, these patents are to serve as defenses in keeping competitors from copying their products, or as offensive weapons to aid in holding a commercial field which the company developed. The laboratory worker surely need waste little sympathy on the leech in business who does no experimental work but spies out the accomplishments of his more progressive competitors and copies their products as closely as he dares. The researcher certainly would not like to feel that his work has gone for naught; that when he has finished his experiments a lazy competitor may appropriate his idea and use it to defeat the end for which he has been working. Patents to prevent such unfair competition are certainly justified. It has always been recognized in civilized countries that one has a right to his discoveries for a limited period of time, provided he keeps his bargain with the public by giving the latter a full disclosure of the invention in return for a short-term monopoly.

On the other hand, one need feel no apprehension

[1]For a clear discussion of this phase of the subject the reader should consult the book "Organization of Industrial Scientific Research," written by Dr. C. E. K. Mees, director of research for the Eastman Kodak Co., published by the McGraw-Hill Book Co., New York.

that the patent covering his particular accomplishment will prevent the progress of the science, since any progressive company which stands on its own feet, does its own experimenting and builds up a business on its own good will and prestige is never seriously handicapped by patents taken out on the other man's work. A patent validly covers only what is new. All that is old belongs to the public. Hence, in view of the large amount of known information preceding that particular piece of laboratory investigation, the patent obtained will not ordinarily be of large scope, but will serve merely to protect the particular field within which the investigation has been made. The competitor obviously is not prevented from developing other fields.

The laboratory worker might better look upon a patent as a written disclosure of a piece of research accomplished and leave the question of legal barriers for the patent attorney to decide. From a more personal viewpoint, the patent stands somewhat as an official certificate of the government that a given person has developed something new, that he has added to the sum total of scientific knowledge, that he is wide awake, progressive, a leader and not a follower.

What Is Patentable?

"What is patentable?" is a question which the research investigator should not attempt to answer. That is one weakness in the average laboratory. A scientist is likely to be overmodest and belittle the results of his work, or, rarely, the man in charge may not be enthusiastic for ideas which he did not personally develop. Again, many ideas when first suggested seem impractical. They probably are, as first thought out, and cannot be made workable without a certain amount of investigation and study. Nevertheless such embryonic ideas may be basically valuable as patent rights. If the laboratory director does not take up the suggested idea, it may lie dormant for years and then perhaps be forced to the front through some change in the commercial field. By this time one's competitors have reached the same stage of commercial development and it is more than likely that the idea will be developed and patented by an outsider.

It is the same with questions of interpretation of a patent. The laboratory man, not being skilled in patent matters, either considers a patent as a barrier to further work or ignores its fine points and may conduct his own work along lines which are prohibited. A patent expert, having a general survey of the whole patent field and knowing the commercial value of patent rights, is in far better position than the laboratory head to decide as to the patentable merit of the laboratory work.

Patent Department

In order that the laboratory may make the most of its opportunities, it must be alive to the patent situation; hence it must have a specialist on its staff or at its call who knows the value and scope of patents, who can advise on questions of infringement and obtain protection for the new ideas. In no way can this be better accomplished than by establishing a patent department. The scope and nature of this department obviously will depend on the size of the company, its research program and questions of finance. Let it be said here, however, that a company large enough to carry on research is too large to neglect its patent protection. This department may be headed, and preferably, by a patent attorney of experience and vision, who is located at the plant. For the smaller company, the department may be run by a younger man, but only under the supervision of an older attorney who is acquainted with corporate problems and who can develop an adequate system. Essentially, the department head must have intimate contact with the inventors and know their work and their problems. He should have full access to the laboratory files, attend laboratory conferences and otherwise be in position to follow closely not only what is being done but, perhaps more important, know what it is proposed to do. In addition, a thorough understanding of the company's program, its sales activities, its manufacturing problems, are all essential to his success in helping the laboratory's work.

Such a department head, or his supervising attorney, must not merely do what he is told to do, as must the outside attorney who has no personal interest in the company and is only called in when some one at the plant, unskilled in such matters, happens to think of the patent situation. The corporation attorney, on the contrary, shoulders the full responsibility of protecting the company's patent interests. For example, the department head may have to rewrite a piece of advertising to correct an improper use of a trade mark; he censors the printing of new labels; he studies competitors' catalogs and their advertising and otherwise keeps a systematic watch for infringements; he collects old records and proofs and establishes a model room showing the historical and inventive progress of the company, which may be invaluable as legal evidence in some future controversy; he is ready with advice to aid the engineer or the research director in choosing his lines of development; he may establish a suggestion system or other method of rewarding employees for their ideas; in fact, he must keep in touch with every phase of the company's business which spells progress.

Other Functions of a Patent Department

Other functions of the patent department involve blazing the trail and finding new paths for development. This requires vision and knowledge of company methods and policies, as well as the public's wants and competitors' activities. Perhaps some basic patent in a new field may be obtained. Every company is being constantly importuned to buy patents. This may in fact be such a large problem as to take much of the department's time. For example, one large corporation receives perhaps a thousand such letters in a year. It requires judgment of patent values as well as of commercial and manufacturing problems to know when not to turn down such offers. Again, the corporation attorney may see the possibilities in obtaining a license under some basic patent held by a competitor, or, on the other hand, in expanding the commercial development of a new field which requires extensive advertising by granting licenses to competitors, as has been done with such basic patents as control the electric lighting field. Another duty of the department is to seek the loopholes in the claims of a competitor's patent and advise the laboratory how to get around the apparent barriers. Such a task needs a man acquainted with corporate methods, full of vision and inventive imagination, a lover of research as well as one versed in patent law and capable of understanding and using discriminating English with all its finer shades of meaning.

When a new research idea is proposed to the patent department, one of the first questions is, Whose field is it? A public common, or land fenced in and culti-

vated, or virgin country? A preliminary patent search tells. The specialist hunts out all the related patents, digs up pertinent scientific literature and reports to the research director on both patentability and infringement. If the scheme is broadly new, all is clear sailing. Usually patents and publications tell of others' efforts along the same line—perhaps failures, perhaps success. What is the situation? If no patent claims are found to be infringed, one is fortunate. Otherwise a path of research must be mapped out, carefully turning this way to avoid a line of patents and that way to meet practical considerations of manufacture and market. This can be done only by patient study by both research and patent departments combined.

Two courses are open for securing patent protection on the new idea: To file a paper patent or to develop the idea by experimentation. Both have their advantages, but the experimental work should not be delayed if the patent is filed first. The original inventive idea may be crude and not acceptable to the manufacturing department. Yet if it can be made to work, the attorney asks no more, if he decides to file an application without delay. (Incidentally, if there is no patent department, the laboratory seldom thinks to take up the basic idea with an outside attorney at this stage.) The draftsmen take the crude idea and with the inventor's help draw up a design sufficient for patent drawings. A patent application is filed and the important date, in the eyes of the Patent Office, of completion of the invention is established. The laboratory or engineering department may then, at its leisure, work out the details of the scheme, design an appliance, build it, test it and get it ready for the market. When practical and complete, if the final product is radically different from the one filed in the Patent Office, a new application may be filed on the details of novelty over the first crude scheme; or the old application, if it has not gone to patent, may be abandoned in favor of a new one. The point is that the application pending in the Patent Office during this period of experimentation has given a certain degree of protection ordinarily sufficient to preserve the monopoly.

Department Problems and Equipment

When a patent department is established for a corporation which has never had such facilities, the attorney first finds a degree of suspicion and lack of co-operation which is surprising. This is due largely to the fact that previously the plant has been run on the theory that secrecy was the best policy; but those methods are fast becoming obsolete. However, he must advertise the value of patents and of his services to the inventors and possibly to the company management. The attorney will also find that the value of his services to the laboratory is directly in proportion to the degree of contact which he maintains with the inventors, either personally or through a personal representative. Periodical intimate talks with the different inventors are necessary. He must attend the laboratory conferences. A conference between investigator and the attorney and a short search through the patents and literature to find the related art will put the former on the proper line of attack with the least waste of time and effort.

A necessary part of the patent department's equipment is a patent file containing all of the U. S. patents and the available foreign patents relating to the art, as well as an accessible and adequate library. The number of patents relating to a given field is sometimes surprising; for example, there are over 12,000 U. S. patents relating to the abrasive industry. Such a file is particularly necessary these days owing to the handicaps under which the U. S. patent examiners work and their inadequate resources. Furthermore, the U. S. Patent Office takes no responsibility in granting an improper patent; the patent department must therefore see that its patents actually protect. Hence the specification writer must have a full survey of the field before him when he draws his claims and when he reports on questions of infringement.

The patent file serves an equally useful purpose for preliminary patent searches to advise the laboratory of the related art before experiments are started. The expense of having such searches made in Washington would of course be far greater than the cost of such a file. Moreover, since but a small percentage of the patents granted ever get into commercial use, and yet many of them are not only practical but possess ideas of merit, it is desirable to go over the disclosed art occasionally to bring the old ideas to the attention of the experimental worker.

It will be found that the patent department handles much chaff when considering the laboratory inventions. One large corporation finds that about one-third of the ideas proposed are of patentable value. I have found that the percentage may run considerably lower. It it not wise to ignore the simpler ideas, since these may ultimately develop into practical schemes.

As to the practical application of the outlined system, the following facts may be of interest: One large corporation within my knowledge originally filed less than four patent applications per year. After a patent department had been established it was found that the same body of workers produced seventeen patentably valuable ideas in three months' time. Another and larger corporation with a progressive research laboratory filed twenty-eight applications in one year before the patent department was established. After two years of patient work on the part of the patent attorney in studying the field and searching out the inventions, about fifteen applications were filed each month. Where such investigators had previously limited their activities largely to factory problems, the stimulus due to the patent department's activities helped to expand the laboratory's viewpoint and led to the development of commercial products which might never have been produced.

Vision

In conclusion, it might be well to state that one of the strongest patent monopolies in this country is held by a company which has in effect merged its engineering and patent departments and placed the research and inventive functions of the organization under the control of an executive committee for experimental work, made up of members of both departments. A member of this committee recently said of their new policy:

"It will not be possible to sell the old line of machines, as the users are supplied for years to come; hence it is now necessary to invent and design new machines so much better and cheaper than the old ones that it will be an economy for users to scrap the old and purchase the new."

With such vision, the engineers are eagerly pushing ahead to bigger fields and their company cannot help but succeed. Enthusiasm always wins.

A Study of the Saturated and Unsaturated Oils From Shale*

Results of Experimental Work on the Composition and Properties of the Lighter Fractions and Heavy Undecomposed Residues Resulting From the Pyrolytic Treatment of Crude Shale Oils

By C. W. BOTKIN
Research Chemist for the American Shale & Petroleum Co.

IN PREVIOUSLY published papers on saturated and unsaturated oils from shale[1,2] the author has presented data which indicated the following facts relative to the saturation and decomposition of certain crude shale oils: As obtained from plant and laboratory retorts, these oils consisted of 12 to 40 per cent of constituents (saturated compounds) unabsorbed by cold concentrated sulphuric acid and 60 to 88 per cent of materials removed by treatment with this acid. The crude oils decomposed readily on distillation at atmospheric pressure and formed coke, gas and lighter oils containing 15 to 83 per cent more saturates by volume than the original oil. The decomposition occurred during the distillation of the heavier fractions, was greatest for oil which had been retorted with steam, and was practically completed by one distillation. The lighter fractions were more highly saturated and the saturation diminished as the specific gravity of the fraction increased. Distillations with steam, with inert gases, and under diminished pressure tended to prevent the cracking, but the oil obtained in all cases contained a lower percentage of saturates. The statements which concern the decomposition of crude shale oils and the effect on saturation are based on experimental work with five different oils from Colorado, Utah, and Nevada shales.

Further Study on the Pyrogenetics of Shale Oils

The effects of the decomposition as shown by these oils may be looked upon with favor by the refiner, since cracking improves the quality of the oil and increases the quantity of gasoline, which is the most highly saturated portion; but new problems are presented to the oil chemist, since an increase in saturation as a result of decomposition at atmospheric pressure is at variance with the usual conception of the cracking of petroleum oils. In the former papers it was suggested that this strange phenomenon might be caused by the decomposition of heavy unstable unsaturated compounds, but that more experimental evidence as to the composition of these materials was desirable. From both practical and theoretical standpoints it appears of interest and importance to determine to what extent this behavior is true of other crude shale oils, and to study the lighter fractions obtained by cracking and the heavy undecomposed materials with the hope of ascertaining more regarding the cause of this unusual example of pyrogenetics and of increasing our knowledge concerning the composition and properties of the constituents involved in the decomposition. It is the purpose of this paper to present the results of additional experimental work along these lines.

Decomposition of Crude Shale Oils on Distillation

Crude shale oils from other fields (see Table I) than those studied in the former papers have been examined to determine the amount of decomposition on distillation and the effect of the cracking on the content of saturates and nitrogen. The Scottish oil was produced in the plant of the Oakbank Oil Co., Ltd., and the Norfolk oil in an experimental retort on the property of the English Oilfields, Ltd.[3] The other oils were obtained by distillation in laboratory retorts operated at moderate temperatures without steam using shales representative of localities in the fields mentioned in Table I.

A portion (50 or 100 c.c.) of each of the crude oils was distilled from a Pyrex distilling flask the capacity of which was double the volume of the oil used. The distillation was conducted at the rate of about one drop a second until the formation of a hard coke. The water was measured by volume. The weight of the coke was obtained as the difference between the weight of the empty flask and the weight of the flask and contents after the distillation. The crude and once-run oils were measured both by volume and by weight. The percentages of gas were calculated by difference.

Tests were made on the crude and once-run oils for gravity and saturation by the methods used for the oils previously studied.[4] Six of the oils of most varied nature were analyzed for nitrogen both before and after the distillation. In making the nitrogen determinations the oils were first washed five times with an equal volume of hot water to remove soluble nitrogen compounds. The oils were then kept warm for 24 hours to insure a rather complete separation of the water. The nitrogen analyses were made by the following modification of the Kjeldahl-Gunning method: A sample of the oil (2 to 3 g.) is digested in a 650-c.c. Kjeldahl flask with 10 g. potassium sulphate, 0.3 g. anhydrous copper sulphate and 45 c.c. of 96 per cent sulphuric acid. After the oil has been completely decomposed, the flask is cooled and 300 c.c. of water added. The flask is again cooled and a small piece of paraffine introduced to prevent foaming. The usual excess of sodium hydroxide solution is run gently down the inside of the flask, a few pieces of zinc shot are immediately dropped in and the distillation is then made in the usual manner. The ammonia is distilled into 0.1 *N* sulphuric acid and the excess titrated with 0.1 *N* sodium hydroxide, using

TABLE II—YIELD, GRAVITY AND SATURATION OF PRIMARY AND SECONDARY GASOLINE

	Colorado Crude — Retorted at Low Temperature Primary	Secondary	Colorado Crude — Steam Retorted Primary	Secondary	Colorado Crude — Retorted at High Temperature Primary	Secondary	Nevada Crude — Primary	Secondary	Wyoming Crude — Primary	Secondary
Yield, per cent	20.3	5.1	13.6	10.5	29.0	2.7	2.62	5.83	26.5	8.0
Gravity	0.783	0.779	....	....	....	....	0.820	0.785	0.787	0.790
Saturation, per cent	51.0	54.0	50.0	50.6	52.4	57.0	58.8	60.2	48.2	49.8

cochineal as indicator. These analyses were all made in duplicate and where the results did not agree within the limits of experimental error the determinations were repeated until the correct percentages were assured.

The results obtained by the distillation and analyses of these crude and once-run oils are given in Table I, which also contains for convenience similar data for four of the Colorado, Utah and Nevada oils previously studied (the first four oils in Table I). The "additional saturates" of Table I are the new saturates formed by cracking and are calculated from the volume of the saturates in a 100 c.c. of crude oil and the volume of saturates in the once-run oil obtained from 100 c.c. of this crude, by subtracting the first volume from the second. The percentage given is the amount of saturates formed by cracking expressed in percentage of the original crude oil. The "loss of oil" is the sum of the percentages of gas and coke, and does not include the water, since this was present in the crude oil and not formed by the decomposition. The "loss of nitrogen" is the total nitrogen lost in coke, gas and in the water-soluble compounds of the once-run oil, expressed in percentage of the nitrogen present in the crude oil.

Discussion of the Results in Table I

From the data in Table I it is evident that all the crude oils tested decomposed to some extent on distillation and that the decomposition was accompanied by an increase in saturation and a decrease in nitrogen content. There is, however, quite a wide range in the amount of these changes. The California oil, which in many ways resembles petroleum, is little changed in gravity, saturation or nitrogen content and forms but 5.5 per cent of gas and coke, while the Kimmeredge oil from the Blacktsone seam decreases 0.134 in gravity, has an increase of 40.8 per cent in "additional saturates" and forms 21 per cent of gas and coke. These two oils are probably extremes, while the others, which lose 5 to 19 per cent as gas and coke, decrease from 0.016 to 0.050 in gravity, yield 6 to 17 per cent of "additional saturates" and lose 8 to 35 per cent of the nitrogen, are probably more representative of shale oils as a class. However, crude shale oils from different strata in the same locality may vary in these respects, but at present no data are available on this question. It is also known that crude oils retorted from the same shale under different conditions vary considerably in degree of decomposition.[5]

[5]Chem. & Met. Eng., vol. 24, May 18, 1921, p. 878, Table III.

It is evident by a comparison of the results given in the last part of Table I that there is no quantitative relation between the "loss of oil" and the "additional saturates" or the "loss of oil" and the "loss of nitrogen." But where the percentage losses of nitrogen are high (17 per cent or more) there is a large yield of "additional saturates" (11 to 18 per cent) and where the nitrogen losses are low (8 per cent) the "additional saturates" are smaller (6 per cent or less). This suggests that the "additional saturates" may be formed by a decomposition of unstable nitrogen constituents. The rôle of the nitrogen compounds in the decomposition deserves consideration because 2 per cent of nitrogen in the heavy unstable materials, combined with carbon, hydrogen, and possibly some sulphur to make molecules as high in molecular weight as these materials probably are, would account for the greater portion of the unstable materials. Molecular weights such as $C_{31}H_{61}N$ require but 3 per cent of nitrogen. Many investigators have noted that petroleums high in nitrogen are easily decomposed by distillation at atmospheric pressure.[6] It is possible that this instability may be caused by the nitrogen constituents and that saturation tests before and after decomposition would show an increase in saturation similar to that of the shale oils. The stability of the once-run oils proves that they contain lighter nitrogen compounds not easily decomposed.

Light Oils Obtained by Cracking

Some information concerning the oils produced by cracking at atmospheric pressure can be gained by a study of the lighter fractions of both the crude and once-run oils, since the latter contain the light oils formed by the decomposition. For a number of the crude oils under investigation the percentage, gravity and saturation of the fractions to 410 deg. F. were determined. For the oils given in Table II these values were determined and then this fraction (primary gasoline) was excluded, the remaining fractions composited on distillation and this once-run composite distilled to 410 deg. F. The second light fraction thus obtained (secondary gasoline) consists of oils formed by cracking. The gravity, saturation and percentage of the secondary gasolines are tabulated in Table II with similar data for the primary gasolines. Table III gives similar data for other oils, but here the primary gasoline

[6]Mabery, *J. Soc. Chem. Ind.*, vol. 19, p. 504; *J. Am. Chem. Soc.*, vol. 41, p. 1691. Richardson, *J. Soc. Chem. Ind.*, vol. 19, pp. 122 and 123. Coates and Best, *J. Am. Chem. Soc.*, vol. 25, p. 1151. Peckham, *J. Frank. Inst.*, vol. 146, p. 45. Salathe, 13th Report Cal. State Mineralogist.

is included with the secondary as "total" gasoline and the distillation of one of the crude oils was made with steam. The yields are given in percentages by volume of the original crude oil.

Discussion of the Results in Tables II and III

The primary gasolines from the different shale oils vary in quantity (2.6 to 26.5 per cent) and saturation (42.4 to 60.0 per cent). For oils from the same sample of Colorado shale retorted under different conditions the quantity and saturation of the primary gasoline fraction are lowest for the steam retorted oil (13.6 per cent and 50.0 per cent respectively) and highest for the oil retorted at higher temperatures without steam (29 per cent and 52.4 per cent respectively). For the secondary gasoline the quantity and saturation vary with the field from which the shale was obtained and the quantity is also influenced by the method used in retorting. For the Colorado shale oil mentioned above this quantity was 2.7 per cent where the retorting decomposition was greatest and 10.5 per cent where the retorting decomposition had been diminished by the use of steam. For each shale oil tested the secondary gasoline fraction has a higher saturation (0.6 to 9.0 per cent) than the primary fraction. In other respects these light oils appear to be very similar in composition and properties. This might be expected, since both are decomposition products, the primary gasoline being produced by cracking in the retort and the secondary by decomposition in the still. Both are cracked gasolines and are about equal in quality. Since the prevention of cracking diminishes the yield and does not improve the quality of the gasoline, there is no reason as far as gasoline is concerned for the prevention of cracking either in the retorting of the shale or in the distillation of the oil.

TABLE III—YIELD, GRAVITY AND SATURATION OF PRIMARY AND TOTAL GASOLINE

Saturation, per cent	42.4	51.7	43.2	46.8	60.0	65.6

Unstable Materials of Crude Shale Oils

Since the decomposition which occurs during the distillation of crude shale oils is greatest for the heavy fractions and is diminished by distillations with steam, the unstable materials should be found in large quantities in the heavy residue remaining after the lighter oils have been removed from the crude by distillation with steam. Two samples of the heavy undecomposed materials were prepared in this manner. The first was obtained by distilling 4,000 c.c. of a crude Colorado shale oil to coke with steam and reserving the last fraction (200 c.c.) for the experimental work. The second was prepared by distilling 5,000 c.c. of the Utah crude No. 2 with steam but leaving a residue of 700 c.c. which was poured from the still while hot and is the "shale-oil residue" mentioned in the remaining portions of this paper.

The first sample, which for convenience will be designated as "cut ten," was a yellowish brown, sticky, semi-solid. It became much darker and slightly harder on exposure to air. When cooled slightly below room temperature the "shale-oil residue" was a black, lustrous solid, but very tenacious and sticky at higher temperatures. Tests were made on "cut ten" for specific gravity, saturation and solubility; and a portion was destructively distilled and the resulting oil examined. The results obtained with "cut ten" are given in Table IV. Solubility, saturation and fixed carbon determinations were made on the "shale-oil residue," using the methods for bitumens given in Richardson's "Modern Asphalt Pavement," 1910. A portion of this residue weighing 450 g. was destructively distilled at atmospheric pressure from a 1,000-c.c. Pyrex distilling flask. The yields of gas, coke and oil were measured and the oil fractionated into 10 per cent fractions, each of which was tested for gravity and saturation. The "shale-oil residue" and the oil obtained from it by distillation were analyzed for sulphur by the method of Waters[7] and for nitrogen by the Kjeldahl modification already described. The data obtained with the "shale-oil residue" and the oil produced from it by distillation are given in Table V.

Discussion of the Results in Tables IV and V

"Cut ten" and the "shale-oil residue" were found to contain 90 to 95 per cent of unsaturates and 83 to 88 per cent of malthenes; hence these heavy materials consist of a large proportion of unsaturated malthenes. The percentage of sulphur (0.37 per cent) in the "residue" is much lower and that of the nitrogen (2.05 per cent) higher than Richardson[8] gives for the malthenes of Trinidad asphalt (2.9 and 0.6 per cent respectively).

TABLE IV—DATA ON "CUT TEN" FROM STEAM DISTILLATION OF CRUDE SHALE OIL

Specific gravity	1.0216
Saturation, per cent	5.4
Solubility in carbon bisulphide, per cent	100.0
Malthenes, soluble in 84 deg., Bé. petroleum ether	88.0
Products of Distillation

Changes Produced by Distillation	Gravity	Saturation Per Cent
Before distillation	1.0216	5.4
After distillation	0.959	50.0
Additional saturates		27.8

Results of Fractionation	Per Cent	Saturation Per Cent
Water, by volume	0.28	..
Oil to 410 deg. F.	14.0	60.5
Oil to 572 deg. F.	21.1	49.5
Oil to 680 deg. F.	59.4	40.2
Gas and coke (by difference)	5.2	

On distillation at atmospheric pressure "cut ten" and the "shale-oil residue" exhibit a greater decomposition, increase in saturation and loss of nitrogen than the crude shale oils. The "residue" formed 46.6 per cent of gas and coke, lost 72.8 per cent of the original nitrogen and formed 23.3 per cent of "additional saturates," while the Utah crude No. 2, from which this "residue" was obtained, yielded 16.7 per cent of gas and coke, 16.7 per cent of "additional saturates" and lost 28.2 per cent of the original nitrogen. These differences are, of course, caused by the higher content of the unstable materials in the "shale-oil residue." It is probable that the saturates of the "residue" do not decompose on distillation owing to greater stability, but the other materials evidently undergo almost complete decomposition, since 46.6 per cent is transformed into gas and coke, 23.3 per cent into "additional saturates" and 3.2 per cent is present as new unsaturates in the light highly

* Determined by the method on p. 544, Richardson's "Modern Asphalt Pavement," 1910. This result is probably too high. This method is inaccurate for some bitumens the saturates from which are sticky, or hard and resinous, and certainly not paraffines but possibly neutral esters or polymers of unsaturates which are soluble in the petroleum ether and not removed by the treatment with acid and alkali. See Brooks and Humphrey, *J. Am. Chem. Soc.* vol. 40, pp. 847 and 856.
† The average of two determinations.

saturated fraction of the oil boiling below 346 deg. F. The oil obtained by the destructive distillation of the "residue" resembles the once-run Utah oil No. 2 in that it does not decompose on distillation and in the distribution of the saturates, but the boiling point and specific gravity of the fractions are lower and the saturation higher than in the fractions of the once-run oil. Since the once-run oil from the Utah crude No. 2 contains less than 46 per cent of saturates, while that from the "residue" obtained from this crude contains 54 per cent of saturates, and since the secondary gasolines have a higher saturation than the primary gasolines, it is probable that the materials escaping decomposition in the retort crack on distillation with a higher yield of saturates than the materials that decompose in the retort. The most remarkable property of the decomposition of the "shale-oil residue" is the large yield of saturates, the greater portion of which consists of lighter oils (72 per cent of the first 10 per cent fraction).

Crude shale oils are apparently composed of comparatively light stable oils of higher saturation produced by decomposition during retorting and of heavy unstable materials of lower saturation that have escaped decomposition in retorting because of rapid removal as vapor and fog by the gases and lighter oils. The decomposition from kerogen to once-run oil tends to occur in two stages—a primary decomposition in which the insoluble kerogen is changed, possibly by depolymerization, into soluble heavy unstable materials similar to the "shale-oil residue"; and a secondary decomposition (not depolymerization) in which these unstable materials are broken down into lighter oils of greater stability and higher saturation such as constitute the once-run oils. Since the secondary gasolines and the light fractions of the oil from the "shale-oil residue" have a higher saturation than the primary gasolines, the primary decomposition must also yield light oils which contain a larger proportion of unsaturates than the light oils formed by the secondary decomposition; or the primary decomposition produces unstable materials lighter than the "shale-oil residue" which yield on secondary decomposition a larger percentage of unsaturates than the heavy "residue" examined in this work. Retorting with steam and inert gases tends to prevent the secondary decomposition[9] by carrying over larger amounts of the bitumen produced by the primary decomposition, and as a result the crude oil contains a higher percentage of the unstable unsaturated materials. Destructive distillation of shale or distillation of crude shale oil at slower rates or under any conditions which tend to prevent the removal of the primary products in the form of fog (heavy non-gaseous vapor) causes a more complete secondary decomposition and produces an oil of the once-run type. Much of the so-called high-temperature retorting apparently evolves the products so rapidly that the gases and lighter oils carry large proportions of the primary products out of the hot zone before the slower secondary decomposition has progressed far, and the crude oil is consequently more highly unsaturated. It is evident that physical conditions during retorting can be so controlled as to obtain a maximum of the bituminous products of the primary decomposition or an oil similar in quality to the once-run oils in which the secondary decomposition is complete, and that consideration of these two stages of the decomposition is important in the construction and operation of retorts on a commercial scale. Since the heavy primary decomposition products of shale may prove to be of commercial importance, these materials should be thoroughly investigated.

Summary

1. Crude oils from shales of wide geographical distribution and of varied chemical composition have been examined and their heavy fractions found to decompose on distillation at atmospheric pressure. The decomposition is accompanied by the formation of coke, gas and lighter oils which contain considerably more saturates and less nitrogen than the original crude oil. The increase in saturates appears to be associated with the loss of nitrogen rather than with the loss of oil.

2. The light oils obtained by the decomposition of crude shale oil are a little higher in saturation than the light oils present in the crudes before the decomposition but in other respects these light oils are similar.

3. The undecomposed bitumen from a crude shale oil was found to consist largely of unsaturated malthenes, high in nitrogen and low in sulphur. A sample of this material decomposed almost completely on distillation at atmospheric pressure forming coke, gas and lighter stable oils which contained a larger proportion of saturates, but a similar percentage of nitrogen to that in the once-run oil from the same crude as this bitumen. This unstable material is a primary decomposition product of kerogen and is the parent material from which the lighter, more saturated stable oils are formed by a further secondary decomposition. Crude shale oils as usually obtained consist of both primary and secondary decomposition products.

The author wishes to express his indebtedness to R. W. Boyd, who did the experimental work with the shale oils from California, Kentucky and England.

Grain Growth and Recrystallization in Metals
II—Experimental Data and General Laws

Consideration of the Effect of Time and Temperature of Heating, Degree of Cold-Work, Original Grain Size and Obstructing Impurities on the Grain Growth of Metals and Solid Solution Alloys —Non-Uniform Conditions Have Powerful Effect on Results of Any Treatment*

By ZAY JEFFRIES and R. S. ARCHER
Research Bureau, Aluminum Co. of America

THE appearance of the grains of a cast metal on a plane surface cut through the metal usually gives no indication of the mechanism of their formation. Each grain appears uniform within its own boundaries and does not suggest that it has grown by a process of dendrite formation. That such is the case is revealed by examining an exterior surface of the metal which has been allowed to solidify freely and upon which the dendrites will usually be found in relief. An illustration was given in an article by the present authors entitled "The Crystalline Structure of Metals" (CHEM. & MET. ENG., May 4, 1921, p. 771). Fig. 1 is a micrograph of a cast brass containing 90 per cent copper and 10 per cent zinc. The structure approximates that of a pure metal, showing pohydedral grains uniform in appearance within themselves except for slight changes in etching tint due to concentration of the zinc near the grain boundaries. This effect is known as "coring" and regularly occurs during the solidification of alloys which in equilibrium consist of homogeneous solid solutions.

Cored Crystals

As the amount of impurity increases the coring effect becomes more marked. In Fig. 2 is shown a cast brass containing 70 per cent copper and 30 per cent zinc. Under equilibrium conditions about 35 per cent of zinc is soluble in copper in the solid state, but equilibrium is not attained during solidification and the structure shows marked coring with perhaps the separation of a second phase. The dendritic structure of the primary copper-rich grains is clearly shown. Fig. 3 shows a similar structure in cast Monel metal, which contains about 60 per cent nickel, 35 per cent copper and 5 per cent iron and manganese. Both this alloy and the 70:30 brass after working and annealing exhibit perfect solid solution structures, indistinguishable under the microscope from those of a pure metal. These illustrations show not only the tendency of metals to crystallize in the form of dendrites but also that the solid solution alloys are not homogeneous solid solutions in the cast state. This is important because the discussions below deal with grain growth in substantially pure metals and solid solution alloys which after a homogeneous structure is produced follow the same laws of grain growth as pure metals.

On solidification the amount of the added element in an alloy of the solid solution type influences the grain size. This is particularly true in case of sharp variations of temperature between different parts of the solidifying alloy. Whereas pure metals cast in iron molds or otherwise caused to solidify rapidly nearly always show smaller grains than when cast in sand molds or caused in any other way to solidify slowly, solid solution type alloys often show larger grains when cast in chill molds. There seems to be a certain temperature gradient and composition favoring the formation of large grains. The solidification of an ordinary steel ingot in an iron ingot mold seems to produce the proper conditions for large grains in the exterior of the ingot and considerably smaller grains in the interior. It should be remembered that the grain size of cast

*Part I, on Definitions, was published in CHEM. & MET. ENG., vol. 26, No. 8, Feb. 22, 1922, p. 343.

FIG. 4—COARSE-GRAINED TUNGSTEN BRIQUET FUSED AT CENTER. × 25

metals is always large as compared with that ordinarily found in worked metals.

The effect of existing crystals on the crystallization of a liquid is well known. If a crystal of a salt is put in a saturated water solution of the salt and the temperature lowered, the existing crystal grows larger. The added material assumes the same orientation as the original crystal. If the temperature is lowered very gradually, no new crystals may form. This is only one of many cases illustrating that when a liquid solidifies, existing crystals form "nuclei" on which the liquid crystallizes. A good example of this rule was observed when a coarse-grained tungsten ingot was heated by the passage of electric current until the central or axial portion fused. Fig. 4 shows that the grains in the resolidified portion are continuations of the grains in the unfused portions.

When a fine-grained tungsten ingot was fused in the center, however, the metal resolidified in such manner that each grain in the resolidified portion was adjacent to about 100 of the original grains. The structure of such an ingot is shown in Fig. 5. (Sykes). This relatively coarse-grained structure is produced in spite of a rapidity of solidification perhaps seldom equaled in any other metal. The fusion of the ingot breaks the electrical contact and in about one minute the ingot cools from 3,400 deg. C. to about 50 deg. C. Such a cast structure does not show grain growth in the solid state even with long exposures at temperatures slightly below the melting point.

Normal Grain Growth in Solid Metals

Grain growth in the solid state in worked metals and solid solution alloys can be illustrated by the behavior of alpha brass. The structure of a 70:30 brass as cast is shown in Fig. 2. After hot-working or cold-working and heating to a temperature around 600 deg. C. the structure is that of a homogeneous solid solution composed of equiaxed grains. In worked brass the grains are nearly always twinned, although twins are not found in the casting. The history of change in grain size with change in temperature in a 68:32 brass after 50.9 per cent reduction in thickness by cold-rolling is shown in Figs. 6 to 13 inclusive (Bassett and Davis). No grain growth takes place until a temperature of about 275 deg. C. is reached and the cold-worked structure is completely replaced by small equiaxed grains at 400 deg. C. after 30 minutes' exposure. As the temperature increases the grain size increases.

The increase in grain size with temperature can be seen qualitatively in the micrographs and is plotted in Fig. 14. The shape of this curve is similar to that found for many metals by various observers, including Mathewson and Phillips[1] working on alpha brass; Mathewson[2] on copper-tin alloys with 2.4 and 8 per cent tin, and Mathewson and Thalheimer[3] for copper. Rapid increase in grain size begins at about 700 deg. C. for copper.

Although this type of curve is normal for many metals, there are many factors which may and often do cause marked deviations. McAdam[4] shows that cold-worked Armco iron annealed for either 7- or 14-hour periods has a fairly constant grain size up to about 800 deg. C., above which temperature there is a marked grain growth. His temperature-grain size curves are more flat at low temperature than the one shown in Fig. 14, but the increase in grain size above 800 deg. C. is more pronounced than in alpha brass above 600 deg. C. One of the authors has found that the normal grain size-temperature curve for briquetted and sintered tungsten powder[5] is more nearly a straight line than that of Fig. 14. Sometimes when abnormal growth occurs the curve may depart from the normal type entirely within certain temperature ranges.

The time of exposure at the various temperatures is an important factor in the resulting grain size, especially at the lower temperatures. In alpha brass a grain size is reached after a comparatively short time, say 30 minutes, at 650 deg. C., which does not change to any marked extent with longer exposures. If the temperature is 325 deg. C., the time necessary to establish apparent equilibrium grain size is measured in days. Fig. 15 shows the time necessary at various temperatures to produce a given amount of softening in alpha brass (Mathewson and Phillips). If, however, the temperature is raised to a little below the melting point, a fraction of a minute is often sufficient to produce a grain size which does not change noticeably on further exposure. Incandescent lamp filaments of tungsten operated

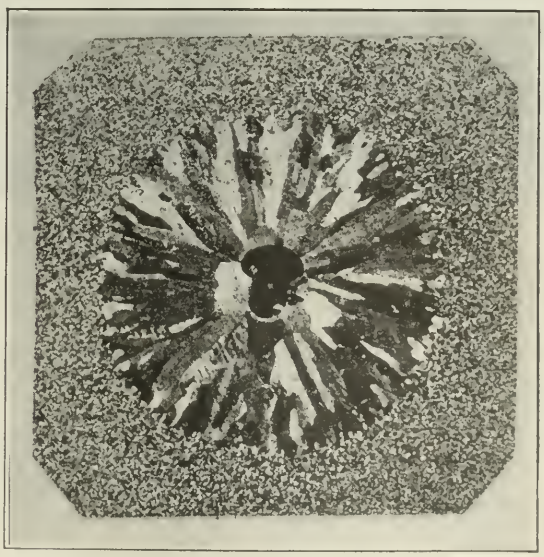

FIG. 5—FINE-GRAINED TUNGSTEN BRIQUET FUSED AT CENTER. × 6. (SYKES)

at a temperature of about 2,100 deg. C. usually exhibit growth until "burn out," which is sometimes as long as 90 days' total heating[5]. The same filaments can be heated to a temperature just below the melting point (3,400 deg. C.) and in a few minutes or sometimes in a fraction of a minute a

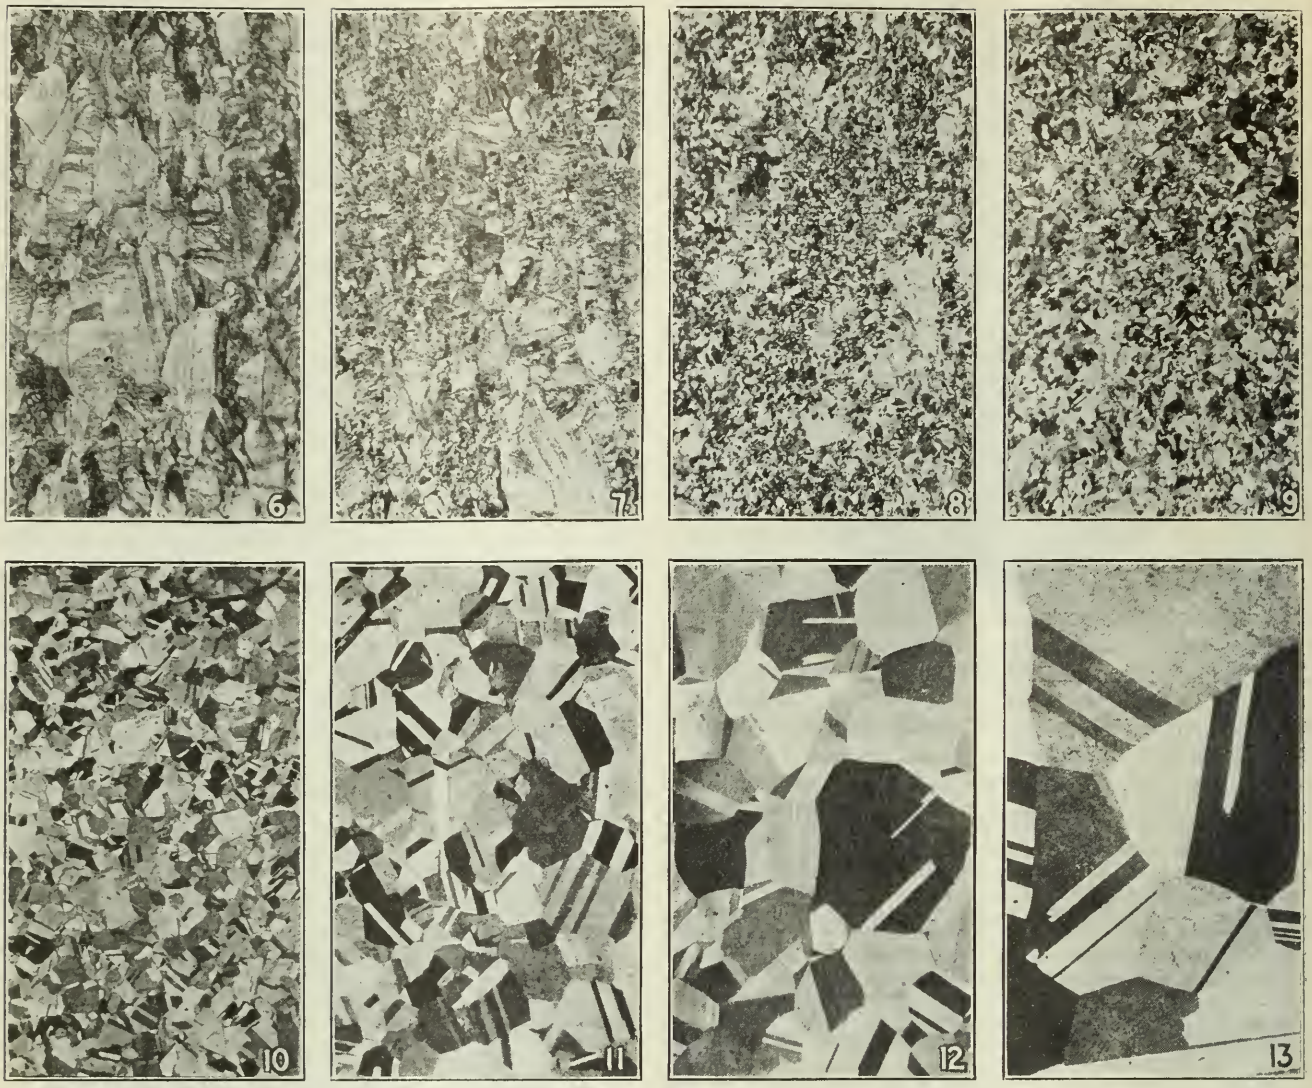

FIGS. 6 TO 13—EFFECT OF 30-MINUTE ANNEAL ON GRAIN SIZE OF 68:32 BRASS, REDUCED COLD 50.9 PER CENT. × 75 (BASSETT AND DAVIS)

Fig. 6—As rolled. Fig. 7—Annealed at 300 deg. C. Fig. 8—Annealed at 350 deg. C. Fig. 9—Annealed at 450 deg. C. Fig. 10—Annealed at 550 deg. C. Fig. 11—Annealed at 650 deg. C. Fig. 12—Annealed at 750 deg. C. Fig. 13—Annealed at 850 deg. C.

grain size will be produced which does not change noticeably when the filament is subjected to a lower temperature; at 3,000 deg. C. 30 seconds often suffice.

A severely cold-drawn nickel:iron alloy containing 56 per cent iron and 44 per cent nickel with a melting point of about 1,475 deg. C. was heated to 1,200 deg. C. for 30 seconds and a grain size was developed which did not change with longer exposure at that or lower temperatures. The same alloy required several hours at 725 deg. C. to produce a similar stability of grain size, although the grains were much smaller than those produced at 1,200 deg. C.

Armco iron containing only 0.02 per cent carbon was pressed cold and heated to 850 deg. C. At the end of 1 hour the average grain diameter was 0.0022 in. At the end of 10 hours this had increased to 0.0077 in. and after 168 hours the average grain diameter was 0.25 in. How much longer this growth would have gone on is not known, as the test was not continued.

The important conclusions from these observations are (1) that under some conditions of temperature, particularly at relatively high temperatures, a grain size is established in a very short time which is stable so long as the metal is not subjected to a higher temperature, and (2) that there is in some metals an intermediate temperature range (which is around 2,100 deg. C. for tungsten and 850 deg. C. for iron) at which grain growth continues for long periods and very large grains may be developed. This intermediate temperature range is not found in all metals. When it does obtain, an abnormal grain size may develop. Carpenter and Elam[6] report that large grains are developed in commercial aluminum sheet severely worked and annealed for 2 weeks at 550 deg. C.

Recrystallization

A great amount of work has been directed toward the study of the phenomena of recrystallization. Recrystallization has been defined in the first of this series of articles as the change from the strain-hardened to the un-strain-hardened condition. When recrystallization is complete the small unstrained grains grow into larger unstrained grains in accordance with the general rules just considered.

The greater the degree of strain-hardening the lower will be the temperature of recrystallization. Consequently with a metal of a given composition—i.e., a given degree of purity—anything which will increase the degree of strain-hardening will decrease the recrystallization temperature. The amount of deformation effected below the recrystallization temperature is one

[6] "Crystal Growth and Recrystallization in Metals," Carpenter and Elam, *J. Inst. Metals*, No. II (1920).

factor influencing the degree of strain-hardening. The general rule is that the recrystallization temperature is lower the greater the amount of cold-work.

Mathewson and Phillips show that in alpha brass, previously annealed at 800 deg. C., recrystallization after 4 per cent reduction in area by cold-rolling requires a temperature of 650 deg. C., and after 40 per cent reduction the temperature is 350 deg. C. for a 30-minute anneal. Carpenter and Elam[1] show that commercial aluminum sheet previously annealed for 6 hours at 550 deg. C. and then elongated 2 per cent at room temperature did not show recrystallization or at least complete recrystallization after 65 hours' heating at 500 deg. C. With 4 per cent or more elongation recrystallization was complete under these conditions of time and temperature. With severe cold work the recrystallization temperature may be lowered to 200 deg. C. or less. Usually in such cases the grain size is smaller the greater the previous deformation.

Grain size prior to cold deformation is an important factor in connection with the degree of strain-hardening and hence greatly affects the recrystallization temperature. The smaller the grains the greater is the strain-hardening effect of a given amount of deformation and the lower is the recrystallization temperature. Fine-grained metal elongated 1 per cent may have a lower recrystallization temperature than a coarse-grained metal elongated 5 per cent or more. This disparity in grain size prior to cold deformation may even produce such marked difference that a coarse-grained metal elongated as much as 5 per cent will not recrystallize at a temperature which will cause normal grain growth in an annealed but fine-grained sample of the same metal. For example, a severely cold-worked aluminum sheet heated for several hours at 250 deg. C. will recrystallize. The grains will be small. If the same piece is heated to 300 deg. C., grain growth will take

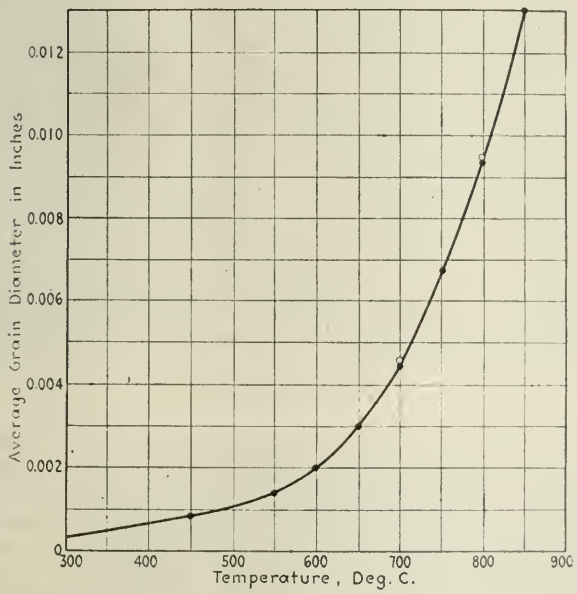

FIG. 14—EFFECT OF 30-MINUTE ANNEAL ON THE GRAIN SIZE OF 68:32 BRASS COLD-ROLLED 50.9 PER CENT. (BASSETT AND DAVIS)

place. A very coarse-grained sample stretched 5 per cent cold may show no signs of recrystallization at 300 deg. C.

Time of exposure at temperature is an important factor in the temperature of recrystallization (refer to Fig. 15). A cold-worked metal which might show only partial or no visible signs of recrystallization in 5 minutes might show complete recrystallization in an hour or more. So far as tests go it seems that the recrystallization temperature becomes lower the longer the time of exposure. When the temperature which will cause recrystallization with a few hours exposure is found, a slight decrease in temperature causes an enormous increase in time to produce recrystallization. So great is this effect that a temperature is found not far below the ordinary recrystallization temperatures which would necessitate an exposure of years to produce recrystallization.

The temperature of deformation is also a factor in determining the recrystallization temperature. The lower the temperature at which the deformation is effected the lower will be the recrystallization temperature. A possible exception to this general rule is iron worked at a temperature near 200 deg. C.

The purity of a metal is also an important factor in connection with the recrystallization temperature. As a rule a solid solution alloy has a higher recrystallization temperature than the solvent metal. For example,

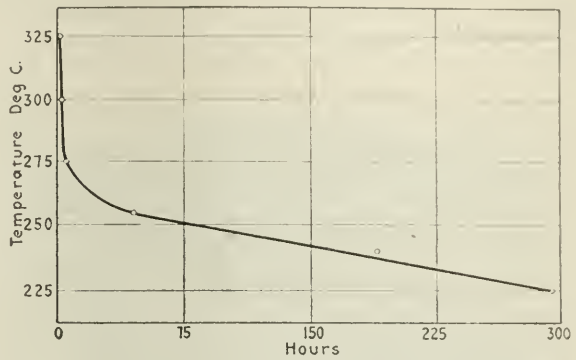

FIG. 15—CARTRIDGE BRASS (70:30) COLD-ROLLED 40 PER CENT. TIME NECESSARY TO DROP 3 POINTS IN SCLEROSCOPE HARDNESS. (MATHEWSON AND PHILLIPS)

severely strain-hardened alpha brass containing 34 per cent zinc has a recrystallization temperature of about 300 deg. C., whereas severely strain-hardened copper has a recrystallization temperature of about 200 deg. C. Impurities producing mechanical obstruction to grain growth also increase the recrystallization temperature.

The recrystallization temperature not only varies for different treatments of different pieces of the same metal, but it varies within the same piece of metal if a homogeneous condition does not exist. Since with mild cold deformation and large grains it is impossible to produce a condition even approximating homogeneity, such samples usually recrystallize over a considerable *range* of temperature. The greater the amount of strain-hardening the smaller this range will be—that is, the complete change in structure from strained to unstrained grains will take place within a small temperature range. Since the properties depend on the structure, there is a marked change with a small temperature change.

If we consider the temperature at which recrystallization is just complete, it is observed that the lower the recrystallization temperature the smaller the grain size. When some condition is varied which raises the temperature of complete recrystallization, such as the amount of deformation, the grain size after complete recrystallization is larger than with the lower recrystallization temperature. With a given recrystallization temperature there is a certain *minimum* grain size which can be produced. This minimum is less the lower the recrystallization temperature in any particular metal.

The disparity in grain size produced by varying the recrystallization temperature tends to disappear as nor-

mal grain growth proceeds above the recrystallization temperature. Equality of grain size is produced only at high temperatures. Figs. 16 to 21, of alpha brass cold-worked different amounts and then heated for 30 minutes at 550 deg. C., show how the grain size becomes smaller as the recrystallization temperature decreases. The grain sizes of the more severely deformed samples were still smaller at temperatures only slightly above recrystallization. If all were heated to about 800 deg. C., the grain sizes would be approximately equal.

The history of recrystallization can be studied by subjecting strain-hardened metal to various temperatures and cooling and examining with a microscope after recrystallization has commenced but before it is completed. This has been done by Chappell[7] on iron, Mathewson and Phillips[1] on alpha brass and Carpenter and Elam[8] on aluminum. In all cases recrystallization begins at the old grain boundaries, preferably at the junction of three original grains. The new grains grow into the original grains with about equal ease.

Because new grains first appear at old grain boundaries, it is too commonly considered that new grains do not appear in the interior of the original grains. By referring to Fig. 9 and comparing it with Fig. 6 it will be obvious that many of the grains in the former must have formed in the interior of the old grains. A case which has been observed frequently is the recrystallization of coarse-grained tungsten after working. The original grains in a particular case were 0.25 in. in diameter. The ingot was worked below its recrystallization temperature about 50 per cent reduction in area and then heated quickly to a temperature well above that of lowest recrystallization. The grains then measured 0.008 in. in diameter. *Most* of the new grains were formed inside the original grains.

Compressed Powders

Grain growth in the solid state in compressed metal powders has been studied most extensively with tungsten[5]. The metal does not consolidate until a temperature is reached far above that of recrystallization after severe cold-work. In tungsten the density of the compressed briquet is usually about 60 per cent that of the consolidated metal. The temperature at which the density becomes normal is about 2,400 to 2,600 deg. C., which is at least 1,000 deg. C. above the temperature of lowest recrystallization after severe cold-working. After the briquet has consolidated it consists of very small grains, which, however, are larger than the original particles of powdered metal. Higher temperatures normally produce larger grains, the same as in recrystallized metals. Special cases of abnormal grain growth in compressed tungsten briquets will be considered in connection with "germination."

Obstruction

Any foreign matter in a metal affects the grain growth characteristics. The foreign matter may be in solution in the metal, it may be present as a mechanical inclusion or as a separate phase or constituent of an alloy. A good example of mechanical obstruction to grain growth is thoria (ThO_2) intentionally added to tungsten for the purpose of retarding the rate of grain growth or of producing smaller grains at any given stage in the life of a lamp. The effect of such obstruction is to introduce resistance to grain growth in approximate proportion to the amount of surface of the obstruction particles. A given amount of obstruction material therefore offers more resistance to grain growth the smaller the particles, or with given sized particles the greater the amount of obstructing material the greater will be the resistance to grain growth.

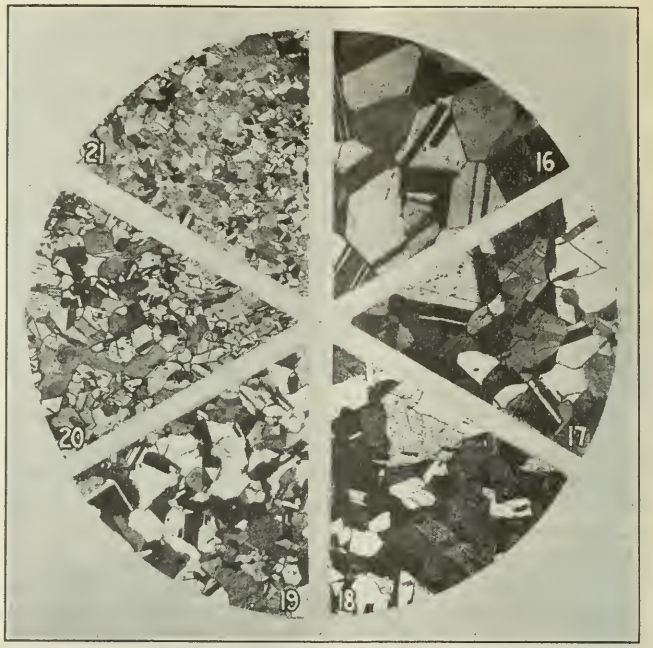

FIGS. 16 TO 21—ALPHA BRASS HEATED 30 MINUTES AT 550 DEG. C., AFTER VARIOUS AMOUNTS OF COLD-WORK. × 60. (MATHEWSON AND PHILLIPS)

Fig. 16—Reduced 4 per cent. Fig. 19—Reduced 15 per cent.
Fig. 17—Reduced 8 per cent. Fig. 20—Reduced 23 per cent.
Fig. 18—Reduced 12 per cent. Fig. 21—Reduced 50 per cent.

Thoria is introduced as thorium nitrate into the tungstic oxide before the latter is reduced by hydrogen to tungsten powder. The heating changes the thorium nitrate to oxide. Thoria is present in such small particles that they are not visible except under a high-powered microscope. With 0.75 per cent thoria present a polished section may cut about 5,000 of these small particles per square millimeter.

Many cases of directional obstruction are encountered in worked metals. Slag in wrought iron sometimes obstructs grain growth more in a direction perpendicular to that of working than in the direction of working. When a tungsten briquet containing approximately 0.5 per cent thoria is sintered at a high temperature, the grains are, as nearly as can be measured, equiaxed. The thoria particles are also equiaxial in shape. When the metal is worked at a temperature near 1,300 deg. C. the thoria globules elongate into fibers which do not change materially when the metal is heated to a very high temperature. The tungsten grains developed in drawn wires containing thoria are nearly always longer in the direction of working than in other directions. It is obvious that threads of thoria will obstruct growth more in a perpendicular than in a parallel direction to their long dimensions[8].

Gradients

The examples of grain growth given above are typical of the results ordinarily obtained and may be considered "normal" grain growths. Such growth usually results when the metal is reasonably uniform in structure and is uniformly heated. There are many instances of grain growth which seem to be in direct contradiction to the laws of normal growth. A careful study of these cases usually reveals that some non-uniformity either in structure or in temperature has been responsible for the apparent paradox.

The most important type of structural non-uniformity is that due to variable strain and may be referred to as a *strain gradient.* There are two types of strain gradient to be considered—"general" and "local." A

[8]Although the thoria fibers are so small that they cannot be seen even with a high-powered microscope, their presence in fibrous form is indicated by the behavior of a coiled wire, when the tungsten is removed by HCl at a dull red heat. The thoria remains in the form of the original coils. When unworked wire is treated with hot HCl gas, the thoria remains unattacked chemically, but is found after the treatment in a compact mass on the bottom of the boat or other receptacle.

Fig. 22—Stressed cold to 40,000 lb. per sq.in.
Fig. 23—Stressed cold to 38,000 lb. per sq.in.

general strain gradient consists in a gradual variation in the degree of strain over a considerable distance in the metal, such as is produced when a bar is bent or when a Brinell impression is made. A general strain gradient is the result of a grossly non-uniform mechanical deformation, but no deformation, however uniform, can be effected without introducing local variations in strain from grain to grain or in different parts of the same grain. These are referred to as local strain gradients.

A second type of structural non-uniformity consists in a non-uniform distribution of material which mechanically obstructs grain growth, and may be designated an "obstruction gradient." Obstruction gradients are generally local in character.

Variations in temperature within a piece of metal are referred to as *temperature gradients*. Temperature gradients always exist during heating or cooling, and are greater the faster the change in temperature. The outside of a piece of metal is always hotter during heating than the inside, unless the heat is generated within the metal, as by the passage of an electric current, in which case the inside may be very much hotter. In ordinary muffle heating the rate is so slow that only small temperature gradients exist, and if the temperature distribution in the furnace is good, the metal may be considered substantially free from temperature gradients. When temperature gradients exist they often play an important rôle in grain growth.

Certain combinations of non-uniformity of structure or temperature give rise to what may be termed "exaggerated grain growth"—that is, the production of grains of abnormally large size. Any case of the development of abnormally large grains may be called *germination*.[9] The temperature range within which the abnormally large grains are formed is called the germinative temperature.

Some typical examples of germination will be considered.

An important type of exaggerated growth was reported by Prof. A. Sauveur,[10] in soft steel containing about 0.05 per cent carbon, given a preliminary normalizing treatment by heating to about 900 deg. C. and cooling in air. Test-pieces were then subjected to definite degrees of strain by stretching in a tensile machine. Prof. Sauveur expressed the strain in terms of the stress to which the specimens were loaded. This is not, of course, an accurate measure of strain if materials of different stress-strain characteristics are being used, but where all experiments are carried out on the same material the stress does indicate the strain. A specimen stretched by a unit load of 40,000 lb. per sq.in. and then annealed for 7 hours at 650 deg. C. showed a marked increase in grain size (Fig. 22). A similar specimen loaded to 38,000 lb. per sq.in. and annealed in the same manner showed no grain growth, nor did germination result if the specimens were loaded to 42,000 lb. per sq.in. or more (Fig. 23).

Similar results are shown qualitatively by making a Brinell impression in a piece of mild steel and then heating it 7 hours at 650 deg. C. The strain is, of course, greatest immediately below the impression and decreases gradually as the distance from the impression increases. In a certain zone marked by coarse grains the strain is just right to produce germination.

Prof. Sauveur bent another bar of mild steel cold and gave it the same heat-treatment. Fig. 24 shows how germination took place in a certain zone between the axis and outside of the bar. Another very clear illustration of the facts is seen

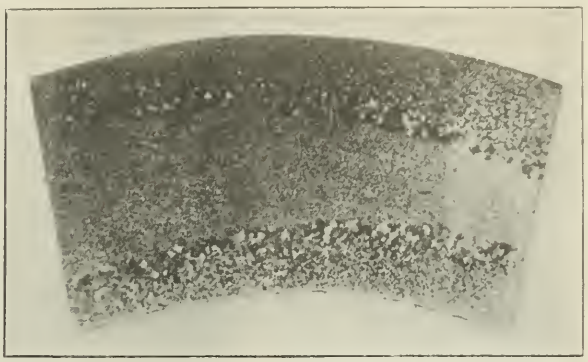

FIG. 24—STEEL (0.05 C) BENT COLD AND HEATED 7 HOURS AT 650 DEG. C. × 6. (SAUVEUR)

in Chappell's[7] tapered bar shown in Fig. 25. The strain increases continuously toward the small end of the bar. It will be noted that, as the degree of strain increases, the point at which grain growth begins is sharply marked. With still further strain, however, the grain size decreases in a gradual rather than abrupt manner.

Prof. Sauveur concluded that there is a critical strain which produces germination. He was unable to produce marked grain growth in Armco iron containing only about 0.02 per cent carbon or in steels containing over about 0.12 per cent carbon. He reports, "It would seem therefore that we must also recognize the existence of a critical carbon content (0.04 to 0.12 per cent) above or below which ferrite grains will not grow on annealing below the range, even if they have been critically strained." The effect of carbon is undoubtedly one of mechanical obstruction to grain growth, so that, translating this last conclusion, we may say that there is a critical amount of obstruction for exaggerated grain

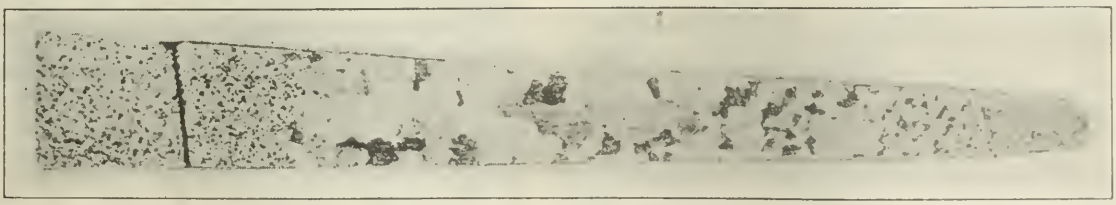

FIG. 25—STRAIN GRADIENT PRODUCED BY STRESSING TAPERED BAR, SUBSEQUENTLY HEATING TO 870 DEG. C. × 5. (CHAPPELL)

[9] "On Grain Growth," H. M. Howe, *Trans.*, A.I.M.E., vol. 56, p. 582.

[10] "The Metallography and Heat-Treatment of Iron and Steel," A. Sauveur, pp. 265-271.

growth. It is now known that some coarsening will occur in steels containing less than 0.04 and more than 0.12 per cent carbon, but the maximum effect is obtained in the range named by Sauveur. It is also now recognized that "critical strain" applies to only one set of conditions as to annealing temperature and obstruction. For each degree of strain there is a critical temperature for germination.

This law is well illustrated by Ruder's results on silicon steel[11] (essentially a solid solution alloy). Pieces of silicon steel sheet were annealed at 1,100 deg. C. and then subjected to various amounts of cold deformation by stretching. Pieces with each degree of strain were heated for 10 hours at 750, 800, 950 and 1,100 deg. C. The results are expressed qualitatively in Table I, where the amount of strain is expressed as per cent elongation. Only three degrees of grain growth are indicated. A blank space indicates that no growth has occurred. "Coarse" indicates very large grains, and "medium" indicates that some growth has occurred, but that the grain size is not so great as where "coarse" is reported.

TABLE I.

Degree of Strain, Per Cent	Annealing Temperature, 750 ° C	800 ° C	950 ° C	1100 ° C.
0.625	.....	.....	.....	Coarse
1.25	.....	.....	Coarse	Medium
2.5	.....	Coarse	Medium	Medium
5.0	Coarse	Medium	Medium	Medium
6.75	Medium	Medium	Medium	Medium

Table I shows that the germinative temperature increases as the degree of strain decreases and that when

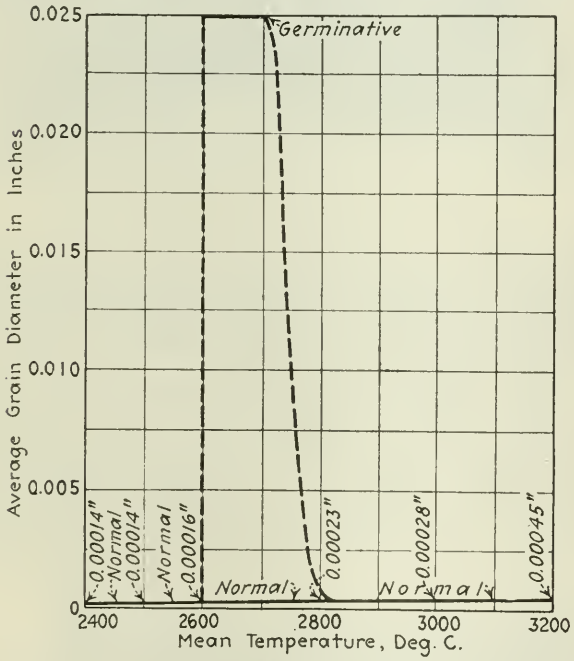

FIG. 26—GRAIN SIZE VS. TEMPERATURE FOR BRIQUETTED TUNGSTEN CONTAINING 0.75 PER CENT THORIA

the annealing temperature is well above the germinative temperature the grain size produced is less than with the same degree of strain but an anneal at the germinative temperature. An additional fact not brought out in the table is that as a rule the grain size produced at the germinative temperature is larger the higher the germinative temperature—that is, the less the strain.

This series shows the effect of rate of heating through the germinative temperature on grain size. For example, in the 800 deg. C. series the 2.5 per cent elongation sample was at its germinative temperature. Consequently in the 1,100 deg. C. series the 2.5 per cent sample was heated rather rapidly through the temperature range around 800 deg. C. and the grain size is smaller in spite of the fact that it was maintained 10 hours at a temperature 300 deg. C. higher. If the

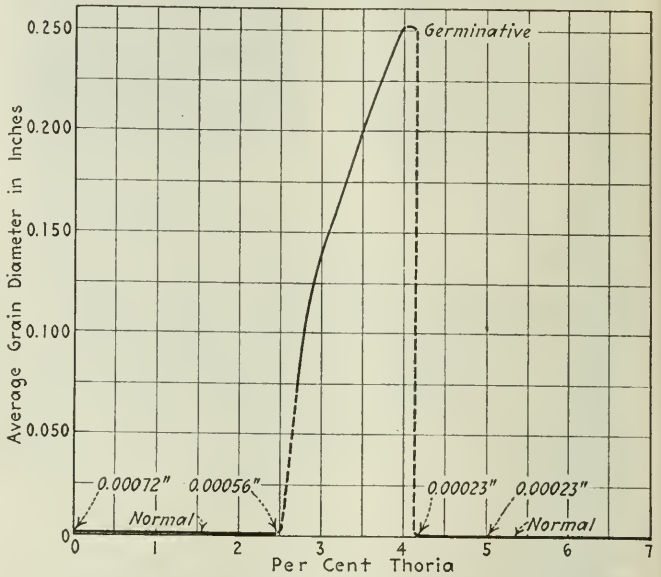

FIG. 27—EFFECT OF THORIA ON GRAIN SIZE OF TUNGSTEN

heating had been slow or if the steel had been maintained at the germinative temperature a long time during heating to 1,100 deg. C., the grain size could not have been smaller than in the 800 deg. C. series and might have been larger.

An example of exaggerated grain growth in tungsten was reported by one of the authors.[12] The normal grain growth-temperature curve for these tungsten briquets in shown by the straight line in Fig. 26. Exaggerated growth can be produced by using metal with a certain obstruction to growth and varying the temperature, at the same time maintaining a temperature gradient. Fine-grained tungsten powder containing 0.75 per cent ThO_2 was briquetted and heated to 2,600 deg. C. by the passage of electric current and held 30 minutes. The portion of the rod near the surface was very fine grained, that at the axis somewhat coarser and the intervening portion was very coarse grained. The axis of the rod was the hottest and the surface the coolest. A briquet of this metal heated quickly to 3,200 deg. C. develops a fairly uniform grain size throughout the briquet and only about one one-thousandth the size of that produced at 2,600 deg. C.

The results of a set of tests on briquets made of very fine tungsten powder containing 0.75 per cent thoria are shown in Fig. 26. Between 2,600 and 2,800 deg. C. there are two curves plotted, one marked "germinative" and the other "normal." The "normal" curve was obtained with briquets of a separate lot of coarser tungsten powder containing 0.75 per cent thoria. Owing to the coarseness of the tungsten particles, no germination took place and consequently the curve is normal. In the fine-grained powder the curve is normal up to 2,600 deg. C. and above 2,800 deg. C.[13] It will be observed that the grain size produced by germination is of a different order of magnitude from the normal grain size.

Many variations in grain size can be produced in the fine-grained tungsten powder briquets by varying the rate of heating to temperatures above that of germination.[5] By heating very slowly to 3,200 deg. C., for example, an average grain diameter of 0.03 in. was produced. By heating to 2,600 deg. C. for 20 minutes and then raising the temperature quickly to 3,200 deg. C. and holding 10 minutes an average grain diameter of 0.007 in. was produced. By heat-

[11] Discussion of Papers "On Grain Growth" and "Grain Growth Phenomena in Metals"; *Trans.*, A.I.M.E., (1916), vol. 56, p. 589.

[12] "Grain Growth Phenomena in Metals," Zay Jeffries, *Trans.*, A.I.M.E., (1916), vol. 56, p. 571.

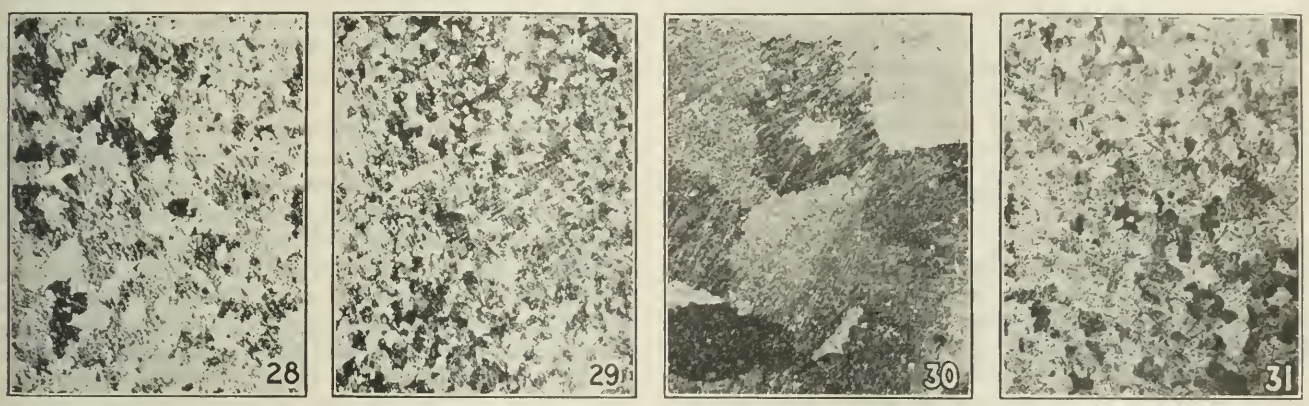
[13] Although the "normal" curves for the two grades of tungsten powder are somewhat different, the variations are not sufficient to indicate on the scale used for ordinates.

ing quickly to 3,200 deg. C. and holding 30 minutes the average grain diameter was 0.00045 in. A study of the history of the formation of the large grains always reveals the fact that in the early stages a few grains reach a size considerably larger than their neighbors. Growth is relatively slow during this stage. As the large grains become larger the rate of growth increases, provided the smaller grains remain unchanged.

When germinative conditions are encountered, rapid heating to a temperature above the germinative range is often the surest and easiest way to prevent the formation of large grains. In the few cases where large grains are desired the rate of heating is again all important.[5]

Germination can be produced in tungsten powder by incorporating the proper amount of obstruction matter (thoria) and heating to a certain temperature by the passage of electric current. Six lots of tungsten powder were prepared containing 0, 1, 2, 3, 4 and 5 per cent thoria. These were briquetted and heated for 12 minutes in an atmosphere of hydrogen at 3,200 deg. C. by the passage of electric current. A temperature gradient obtained from the axis (hottest portion) to the surface of the briquet. The resulting grain sizes produced are shown graphically in Fig. 27. Although the greater amount the grain size after solidification is very large. With still greater amounts of obstructing material the grain size again becomes small. The rate of freezing was the same in all of the tests and the only variable was the amount of obstruction material. Enlarged photographs of this series are shown in Figs. 28 to 31. Because of the "coring" tendency during freezing of solid solution type alloys, a "concentration gradient" might exist. A concentration gradient would produce a freezing temperature gradient which might promote the formation of large grains. In the examples just considered, however, the concentration gradient by itself was not sufficient to produce germination; a certain amount of obstruction was necessary. The same amount of obstruction did not cause germination in commercially pure aluminum. The striking resemblance of the 4 per cent copper series, at least qualitatively, to the series in which the thoria content was varied in tungsten will be noted.[14]

Germination may also be produced by a temperature gradient in a severely strained metal or in iron passing through the allotropic transformation. A condition of grain size contrast which leads to germination may also



FIGS. 28 TO 31. CRYSTAL SIZE PRODUCED ON SOLIDIFICATION OF Al: Cu ALLOY CONTAINING INCREASING AMOUNTS OF OBSTRUCTION MATERIAL

obstruction to grain growth is greater the greater the amount of thoria, there is a critical combination of obstruction, temperature and temperature gradient which produces a germinative condition. This series is particularly important, because it shows how the germinative temperature may be made non-existent by raising it hypothetically to a temperature above the melting point of the metal. The 5 per cent thoria sample can actually be melted without first producing large grains.

Another case of germination in drawn tungsten wire is very interesting.[5] The tungsten metal in question has a small amount of non-metallic obstruction in very small particles. The wire was drawn in the usual way, so that the strain-hardening is very great. If this wire is heated quickly to a temperature near the melting point of tungsten, a fine-grain size is produced. If, however, the temperature is raised gradually by means of an electric current, the structure is very coarse. In fact the grains usually extend across the whole cross-section of the wire and may be as much as 0.5 in. in length. These large grains form in a time not exceeding about 10 seconds. This coarse-grained structure is desirable in certain lamps to prevent undue sagging at high temperatures.

Germinative conditions are not confined to the growth of grains completely in the solid state. The present authors have found that mechanical obstruction introduced in slight amount into a liquid aluminum alloy containing 4 per cent copper produces a moderate refinement of the grain. When introduced in certain develop in a severely strained metal on heating above the recrystallization temperature. In this connection it has been observed that germination often *follows* the first structural changes on heating. For example, a strained metal may recrystallize normally and the recrystallized grains may, at a little higher temperature or on longer exposure, coalesce to form abnormally large grains. In cases of germination due to obstruction and temperature gradients there may be some growth below the germinative temperature.

One method of utilizing the principles of grain size contrast and temperature gradients to produce excessively large grains has been described by Ruder for silicon steel[15] and Schaller for tungsten. Ruder has treated a strip of silicon steel about 1 x $\frac{1}{8}$ x 14 in. in such a manner that it consists mostly of a single grain. Schaller has produced some grains about 7 in. long in tungsten wire of small diameter. The process consists essentially in starting with a material with grains so small that much growth takes place on heating. A small area of the piece of metal is heated to a high temperature in such a manner as to develop large grain locally. The piece of metal is then moved through the heated zone at a rate

[14] "Grain Growth in Metals," Zay Jeffries, *J. Inst. Metals* (1918), No. 2, p. 109.

[15] *Trans.*, A.I.M.E. (1913), vol. 47, p. 569; *J. Ind. Eng. Chem.* (1913), vol. 5, p. 452.

comparable to the rate of absorption of the small grains by the large.

Macromechanism of Grain Growth

Grain growth in the solid state takes place by the gradual absorption of some of the grains by others. This may be referred to as "boundary migration." It was formerly held by some metallographists that whole grains gradually changed orientation until two adjacent ones had the same orientation, after which they suddenly merged. The boundary did not move, according to this view, but disappeared as a boundary on account of the common orientation.

Rosenhain[4] long ago showed that growth in lead took place by boundary migration. One of the present authors[5] reported the results of an investigation showing conclusively that growth in iron took place by boundary migration. Carpenter and Elam[6] have described a most satisfactory method for studying the progress of grain growth in a tin alloy containing a small amount of antimony. When this alloy is etched and heated into the grain growth-temperature range and then cooled to room temperature, the original grain boundaries as well as the new boundaries are visible. Inasmuch as each heating and cooling reveals the new boundaries and does not efface the old ones, as many sets of boundaries as desired can be obtained. Photographs taken after each heating give a splendid record of the history of growth. Carpenter and Elam's results give additional proof that growth takes place by boundary migration.

Laws of Grain Growth

1. The grain size of cast metals is usually smaller the more rapid the rate of solidification.

2. The grain size in cast metals which undergo no phase change in the solid state cannot be changed appreciably by heating below the melting point.

3. Grain growth in the solid state may occur in (*a*) worked metals, (*b*) compressed powders, (*c*) electrodeposited metals, (*d*) in iron when it changes allotropic form and (*e*) in alloys in which a new phase is formed in the solid state.

4. The recrystallization temperature is lower (*a*) the greater the amount of deformation, (*b*) the smaller the grains prior to deformation, (*c*) the purer the metal, (*d*) the lower the temperature at which the deformation is effected and (*e*) the longer the time of heating.

5. In any given metal the grain size after complete recrystallization is normally smaller the lower the recrystallization temperature.

6. Above the recrystallization temperature the grain size is normally greater the higher the temperature and the longer the exposure.

7. The higher the temperature the more rapid the grain growth. At a temperature near the melting point a few seconds is often sufficient to produce grains which may not change further on extended exposure.

8. Certain conditions of non-uniformity sometimes give rise to the formation of abnormally large grains. This is called germination.

9. The non-uniformities giving rise to germination are: grain size contrast, strain gradients, temperature gradients, concentration gradients, and obstruction gradients.

10. The presence of foreign matter or a second phase introduces mechanical obstruction to grain growth. Resistance increases as the quantity of foreign matter or other phase increases and as the particle size decreases.

11. The presence of a certain amount of obstruction matter promotes germination.

12. The higher the germinative temperature the larger will be the grains and the quicker will they form.

13. The more rapid the heating through the germinative temperature range, at least within limits, the finer will be the grain size.

(*Part III, on Underlying Causes, will be published in a Subsequent issue.*)

The Non-Metallic Mineral-Filler Industry

A branch of the mining industry of which comparatively little is known, yet which has been quietly developing to meet a growing demand, is the mineral-filler industry. A discussion of the commonly used non-metallic mineral fillers and their uses in industry is given in an interesting paper by W. M. Weigel, mineral technologist of the U. S. Bureau of Mines, presented before the New York meeting of the American Institute of Mining and Metallurgical Engineers.

The term mineral filler is generally applied to a mineral used in its natural state after mechanical preparation only (such as grinding, milling and washing), without undergoing any chemical change and without exerting any chemical action on the substance with which it is incorporated. The common mineral fillers are white clay, barytes, mica, talc, whiting, ocher, silica, graphite and slate.

Sedimentary or transported white clays are the only clays used to any extent as fillers; the residual white clays, or kaolins, go to the ceramic industry. The principal centers of the clay-mining industry in the Southern district are in the vicinity of Langley, S. C., and in the central part of western Georgia. Clay as a filler is used largely in paper, rubber, oilcloth, paint, and, to some extent, in phonograph records, polishes, textiles, matches and soap. For rubber and phonograph records, the color is not important as long as it is light, but for all other uses whiteness and freedom from grit or quartz are the prime requisites.

Barytes is produced in Georgia, Tennessee, North Carolina and Alabama, Georgia ranking first and Tennessee second in production. It is used as a filler in paper, putty, textiles and phonograph records, but mostly in the paint and rubber industries. In paper, it is used mainly where a high gloss or finish is desired in supercalendered paper and in cardboard. On account of its high specific gravity its use is limited to articles for which it is peculiarly adapted. For paint and paper, fine grinding and pure white color are demanded. For the other uses, fine grinding is desired, especially for rubber, but color is of secondary importance. The content of quartz grains should be reduced to a minimum.

Whiting, the common name for finely ground marble or limestone, is one of the most widely used fillers. True whiting is ground chalk; other ground calcareous materials are substitutes. Production is now confined to Georgia, Tennessee and North Carolina. Both the dry- and wet-ground materials are used in rubber, paint, a few grades of paper, linoleum, oilcloth, shoe polish, putty, tooth powder, roofing, artificial stone and asphalt paving. Other fillers discussed are mica, graphite, talc, silica and ocher. Within the past few years the production of ground mica from schists has been developed, largely because of the rapid increase in the manufacture of ready roofing, which uses most of the low-grade material.

The German and American Synthetic-Ammonia Plants*—IV

Design and Operation of Apparatus Used for Synthesis of Ammonia at Sheffield, Ala., and at Oppau, Germany—Description of Different Processes for Removing the Ammonia—Comparison of the Costs of Construction and Production

By R. S. TOUR

THE purified gases at Oppau enter the circulating system at about 200 atmospheres pressure, there mixing with the gases in circulation, and all pass on to the ammonia catalyst bomb for synthesis. The gas passes through three heat interchangers, two detached and one within the lower half of the catalyst bomb, after which the heated gas passes down through the catalyst bed, back through the heat interchangers, and then through a mist or dust trap, and finally goes to the ammonia absorption installation.

The ammonia synthesizers are arranged in sets, each consisting of the catalyst bomb or ammonia converter with heat interchangers and mist trap. Each set has a rated capacity of about 20 tons of ammonia per day. There are 15 such sets in the main installation at Oppau. They are arranged in a row, set partly below ground level, along, but outside of the wall of the building housing the pumps and special apparatus of the ammonia absorption and circulating systems. The valves, gages, pyrometers and other controls for the ammonia-converter sets are all located within the building. Over the row of converter sets is a protecting steel structure with a 70-ton traveling crane and between the respective converter sets is a brick wall. Thus a separate enclosure is built up for each set.

Construction of the Ammonia Converters at Oppau

The following important features are to be noted in the construction of the converter itself. The shell is 3½ ft. in outside diameter and 40 ft. high, and is made up of two 20-ft. sections bolted together at the middle. Continuous throughout the length of the two sections is a close-fitting steel liner which serves to protect the pressure casing from the action of the gases. The casing is a steel forging, with wall 5 in. thick, perforated radially with ⅛-in. holes spaced about a foot apart. These serve to release gases diffusing through the liner, but allow the casing to carry all of the necessary mechanical stresses. To decrease still further the action of the gases, a later modification of the converters carries an additional liner small enough to leave an annular space between it and the outer liner, and during operation nitrogen under pressure is flushed through this space. Within the liners there is about 2½ in. of heat insulation built up of radial refractory brick. In the upper part of the enclosed chamber is the catalyst container, while in the lower is a heat exchanger. The catalyst is held in an annular space within a tube about 1½ ft. in diameter and around a 4-in. pipe leading the gas from the heat interchanger directly below to the top of the catalyst. The gas passes down through the catalyst and back through the heat interchanger.

The heat interchanger within the converter consists of a nest of about 150 half-inch, thick-walled tubes fastened into headers at each end and carrying baffle plates every few inches throughout their length, which are outside and at right angles to the tubes. This nest is placed within the converter shell in such a way as to carry the inlet gas up through the tubes and the catalyst exit gases through the baffled spaces outside the tubes. After assembling and charging the converter shell, the heads, which in reality are tapered plugs making a steel to steel seat, are forced into position by a hydraulic ram and are bolted into place with sixteen 3½-in. bolts while the ram pressure is still on. The whole bomb (catalyst and heat interchanger) is well lagged by an external insulator so adjusted that air may be circulated between the lagging and the shell for temperature control.

These complicated constructions are necessary for three distinct reasons: (1) The tensile strength, proportional limit, and the other important structural properties of steels, although slightly increasing up to a temperature of about 350 deg. C., rapidly and dangerously decrease with increase of temperature above that value. (2) Hydrogen at high temperature quite readly diffuses into and through steel and within the steel combines with carbon to form methane, which is not diffusible, thus causing blisters, blowholes and dangerous imperfections. (3) Ammonia at temperatures of formation or decomposition has a powerful action on iron, probably to break down completely its crystalline structure, probably by nitrification.

The two detached heat interchangers carry the same type of tube nests as previously described, but the shells are not built for internal heat insulation or nitrogen circulation. The casings are less than 3 ft. in outside diameter by 25 ft. high, forged in one piece and equipped with liners. The mist trap at the exit of the interchangers is of much the same construction as that described for the water scrubbers. The inlet or cooler gases pass through the heat interchangers around the outside of the tubes, while the hot returning gases pass through the tubes. This is the most efficient path.

Operation of the Converters

The catalyst bombs are charged with about 20 cu.ft. of a catalyst developed for the particular operating conditions at Oppau and consisting of practically pure iron specially prepared with an addition of some promotor. The material as used is about ½-in. mesh. Such a catalyst charge, when in use, produces about 20 tons of ammonia per day, or one ton per day per cu.ft. of catalyst. Operating at 5 per cent, this calls for a space velocity of 40,000 cu.ft. of free gas per hour per cu.ft. of catalyst, and a time of contact (allowing

*For Parts I, II and III see Chemical and Metallurgical Engineering, vol. 26, Nos. 6, 7 and 8, pp. 245, 307 and 359, Feb. 8, 15 and 22, 1922.

33 per cent voids) of about one minute within the bed of catalyst.

The matter of the proper speed or space velocity at which to operate a catalyst is of great importance. As the speed is increased the percentage of ammonia in the exit gas is decreased, though not in as great a proportion; thus there is a greater total yield in weight of ammonia. Although this yield of ammonia controls the capacity of the catalyst, still the percentage of ammonia controls the temperature rise due to the exothermic reaction and this is the important factor in the operation of the heat exchangers and in the temperature maintenance of the system. And further, the percentage of ammonia controls the number of times a given quantity of gas must be recirculated before complete synthesis, and therefore governs the size of all the apparatus in the entire circulating system.

The concentration of ammonia produced at Oppau sometimes reached 5 to 6 per cent, but the general average in operation is probably about one per cent less than this figure. It is noteworthy that this represents a relatively incomplete attainment of equilibrium. The rise in temperature due to the exothermic reaction is 75 to 90 deg. C., for a concentration of 4 to 5 per cent of ammonia. This represents the heat available for maintaining the temperature of the system and also supplying the temperature head for heat interchange.

With only this small heat development the system at Oppau is no doubt not self-maintaining in temperature and addition of heat by internal combustion within the bomb is resorted to. The combustion device is also used to start the system when cold. Oxygen (or pure air) under pressure and hydrogen (or the reaction mixture) are supplied through a burner and igniter of special and very neat construction, which projects through the top of the catalyst bomb and maintains a flame in the direct path of the gases just before entering the catalyst bed. The moisture formed by combustion passes on through the catalyst with the reaction gases. One per cent of moisture by combustion will represent a rise in temperature of about 75 deg. C.

Effect of Moisture on the Catalyst

The effect of moisture on the catalyst is a point to be considered very seriously. Since at Oppau water scrubbing is used to remove ammonia from the gases after reaction, all the circulating gases carry some moisture. Saturation at room temperature calls for about 0.01 per cent by volume, but even this makes entirely unusable certain catalysts which, with dry gases, might be highly active and desirable. The type of catalyst developed at Oppau can remain in action in the presence of moisture, still its activity in such an atmosphere is greatly decreased and its operating temperature must be increased. The extent of the inhibition of catalysis depends on the moisture content. The ammonia equilibrium for 200 atmospheres pressure and 500 deg. C. calls for 17.6 per cent of ammonia, with probably 10 per cent of ammonia available from the catalyst when operating on pure gas and at the velocities in use at Oppau. Actual operation with moisture results in less than one-half this amount and further. this reaction reduces the heat generation within the bomb and the temperature head across the heat interchangers, thus making it increasingly more difficult to maintain the necessary temperature. To obviate the effect of such a cycle considerable experimenting is being done at Oppau, looking toward the development of an electrical heater to operate in place of the oxygen burner. Such a new device would have, as additional advantages, increased safety, no loss of pure hydrogen, and better temperature regulation.

In addition to the 15 converter sets, there is still available for operation at Oppau an older installation from which the present plant was developed. This consists of 8 much

smaller converter sets, the catalyst bombs being only 1½ ft. in outside diameter by 30 ft. tall. These bombs are started by external heating applied by combustion of producer gas in a surrounding jacket. Some of this heating is also maintained during operation. This is obviously a dangerous procedure. This old installation connects into the main feeder lines and the exit manifold of the large installation, the ammonia gases passing to the next step, that of ammonia removal.

Ammonia Synthesis at Sheffield

The purified gases entered a high-pressure vessel or mixing chamber in the circulating system at less than 100 atmospheres pressure, there to mix with the gases in circulation. The mixture passed on through 4 heat interchangers, thence through a heater for starting or maintaining the temperature of the system, then through the catalyst bomb at 500 deg. C. and finally back through the heat interchangers.

There was but one set of interchangers and catalyst bomb in the operating unit (Unit No. 1) at Sheffield and this was located in the same building as the purification apparatus and equipment. The ammonia converter itself consisted of a chromium-vanadium forging 4 ft. in inside diameter, 15 ft. high, with walls 3 in. thick. Within this shell was a nest of ninety 2-in. boiler tubes, which were to be charged with 50 cu.ft. of catalyst. The gas entered at the bottom of the shell, passed up around the tubes, then down through the catalyst and out at the bottom of the shell. The heads of the converter were designed to make a special type joint with the shell, making use of the internal pressure to keep the joint tight; this device, however, proved troublesome and unsuccessful. Otherwise the entire construction was very simple compared to the bomb at Oppau. Within the converter, no arrangement was made to protect the bomb from the action of the gases, or to keep it cooler than the operating temperature.

The heat interchangers consisted of forged steel shells 2 ft. in inside diameter, 14 ft. high, with 3-in. walls. Within each shell there was a nest of tubes of very special construction. Each tube element of the nest consisted of 3 concentric tubes, thus having two annular spaces between them. The two gas flows interchanging heat passed each other through these annular paths. No use was made of the volume around the tube elements. This arrangement is ingenious and leads to a high coefficient of heat transfer per unit of transfer surface, but also leads to high friction per unit of heat transferred. Larger apparatus per unit of transfer surface is also required. By a system of valves in the interconnections between interchangers, any one of the interchangers could be bypassed during operation.

Heating of the Gas

A heater, similar in type to a standard steam superheater, was situated so as to heat the circulating gases just before they entered the catalyst bomb. The gas flowed through a series of high pressure tubes connected with flanged joints in a gas-fired furnace of three passes. This heater was the source of much trouble due to bursting tubes and leaking joints and prevented any continuous testing of the circulating system as a whole. This type of heating is subject to two inherent objections: (1) The heat transfer surface must operate at a high temperature and at the same time retain its strength. (2) The efficiency of a furnace furnishing heat at such a high temperature level is necessarily very low. These two objections can be overcome only by internal heat application, which can be accomplished in two ways: (1) Internal combustion of hydrogen by injection of oxygen, and (2) electrical resistance heating directly in the gas path. These have been discussed somewhat under the Oppau description. Electrical heating during Sheffield operation could not have been more expensive than the method in use.

During attempted operation, the catalyst bomb was charged with a special catalyst "composed of iron, sodium and nitrogen." During the development of this catalyst, laboratory experiments with pure gas had indicated that at a space velocity of 5,000 cu.ft. of free gas per cu.ft. of catalyst about 8 per cent of ammonia might be expected in the gas. This catalyst was especially sensitive to poisons, and traces of oxygen-carrying impurities such as O_2, CO_2, H_2O, and CO permanently and rapidly deteriorated its activity. Such a catalyst may be highly active on pure gas, but commercial operation can not be expected to maintain the necessary purity of gases. In fact, at Sheffield, it is doubtful if the desired purity was ever obtained. Operation was so intermittent that statements as to the actual percentage of ammonia converted by the catalyst would be misleading.

Ammonia Removal at Oppau

The ammonia content of the gas is removed by water scrubbing the gas without releasing its pressure, the remaining gas recirculating while the absorbing water is discharged as aqua ammonia. The gas mixture with 4 to 5 per cent of ammonia leaves the converter sets and passes to a main which feeds 8 absorber sets, located on the outer side of the pump house building and opposite the converter sets. In order to secure more favorable temperature conditions for absorption each set first passes the gas through a cooler of 12 coils in parallel, thence to a mist separator and on to the elevated water absorbers. There are 3 absorbers in each set placed one above the other at 20-ft. levels. Each absorber consists of 12 spiral concentric coils connected in parallel, and submerged in a water bath in order to take up the heat of solution generated within the coils. At the exit of each absorber is located a trap to separate the gas and liquid. The water flows downward through the set of absorbers as a whole and the gas upwards, the absorption taking place in three stages, with separation of gas and liquid between stages. In the uppermost stage (third gas and first water stage) water is injected with the gas and the mixture of gas and liquid flows downward through the coils by gravity. The solution from the third gas stage after separation feeds downward to the second and then on to the first. The gas from the first and lowest stage flows to the entrance of the second stage, then on to the third. This arrangement affords a counter supply of solvent although the necessary parallel flow is obtained within the coils of each stage. A newer type of absorber has been installed and used for the last stage of one set of absorbers. This consisted of towers similar to those used in the cuprous formate scrubbing system and provided true counter-current flow at least in the last stage of absorption.

There are 6 steam-driven water pumps (totaling about 800 hp.) for the absorbers. This pump capacity will furnish sufficient water to the absorber sets to give as a final product commercial aqua ammonia of a strength of 25 per cent. Considerably less water

may be used and solutions of much higher strength obtained, but upon release of pressure these evolve gaseous ammonia and leave a 25 per cent aqua. The solution leaving the last separator of the absorber system is discharged to high pressure ammonia receivers, which in turn are discharged when full into closed low pressure reservoirs. Considerable nitrogen and hydrogen gases are dissolved in the aqua and these, released in the reservoirs, are washed with a counter current flow of water to remove ammonia and are returned to the gas holder just previous to the compression stages of the process. The aqua ammonia is finally stored in three large tanks of about 750,000 gal. capacity each.

The high pressure gas in passing through the absorber system gives up most of its ammonia to the water, only about one-fourth of one per cent remaining in the gas. This ammonia content will depend on the temperature at which the last gas stage of absorption was maintained and on the ammonia concentration of the aqua emerging from this last stage together with the gas. Evidently the more water used for absorption the less is the residual ammonia in the gas. However, the hydrogen and nitrogen dissolved and the power required will increase with the increase of water and this represents some small loss in the efficiency of the system.

Ammonia Removal at Sheffield

The intention at Sheffield was to remove the ammonia from the gas by refrigeration at temperatures of —30 or —40 deg. C.; the ammonia was discharged as liquid anhydrous ammonia, while the residual gas was to recirculate back to the converter set. There were two ammonia liquefiers in the installation, each consisting of 7 spiral concentric coils fed from a common manifold and discharging into a common manifold. Inclosing these spirals was a shell 6 ft. in diameter by 15 ft. high, in which the necessary refrigeration was maintained. A standard-type ammonia installation furnished the refrigeration, the ammonia from the condensers expanded directly into the liquefier shells, and the compressors withdrew the evaporated ammonia from the top of the shells. The two liquefiers operated in series on the high pressure gas, although the refrigeration on the outside of the coils operated in parallel in the two shells. The high pressure gas on leaving each of the liquefier coils passed through a mechanical separator where the liquefied ammonia was separated and drained to a pot while the gas passed on through the separator, and thence to a cold interchanger. This apparatus was identical with the heat interchangers previously described and served to cool the incoming gases to the liquefiers by means of the cold gases leaving the system.

To maintain temperatures of —30 or —40 deg. C. it is, of course, necessary to expand the refrigerating ammonia to a considerable vacuum and it is required that the refrigerating compressors operate at that vacuum on the suction stroke. This, in turn, means that the compressors have a much smaller refrigerating capacity in view of the large volume of the refrigerant. It was soon found at Sheffield that although the compressors had the necessary rated refrigerating capacity when operating to make ice under commercial conditions, still they had less than 20 per cent of the refrigerating capacity necessary for the ammonia removal. Additional compressors were, therefore, at once moved over from Units 2 and 3 at Sheffield, together with all spares, and all were connected in the line for operation in Unit No. 1.

The operation of single-stage ammonia compressors with ratios of compression of the order of 20 to 1 must, in general, lead to serious inefficiencies and mechanical difficulties. The operation of two liquefiers in series on the gas with refrigeration on each at the same low temperature level is also inefficient. The first liquefier in the series could be operated to advantage at a higher temperature level and leave only the second liquefier to meet the low temperature requirement. The Nitrate Division in its redesign of the Sheffield plant has laid out a simple installation with standard equipment to operate with compound compression of refrigerant for the low temperature liquefier while the first liquefier operates within a nearly normal ice making cycle.

The total refrigerating capacity may be considerably reduced, although the problem is not greatly simplified where ammonia liquid is not the necessary product of manufacture. In such cases the condensed liquid leaving this high pressure system may be expanded into a liquefier shell, thus effecting considerable refrigeration. This refrigeration would be necessarily independent of the main refrigerating installation in view of the gases dissolved in the synthesized ammonia.

Separation of Condensed Ammonia

The separators for removing the condensed ammonia from the high pressure gas at Sheffield consisted primarily of a vertical baffle plate at right angles to the horizontal flow of ammonia laden gases. No data were obtained as to the efficiency of these simple separators, but general indications were that the ammonia removal was incomplete. The separated ammonia drained from the separator into a high pressure receiver from which it was discharged at intervals into liquid ammonia reservoirs.

The removal of the condensed ammonia from the high pressure gas is a subject requiring serious consideration. Much of the ammonia condenses in the gas as a fine mist difficult to precipitate or agglomerate into larger particles for separation. These in turn are difficult to separate from the gas stream. An analogous but much simpler case is the separation of water from wet steam, which is accomplished in the industry by various types of apparatus, all of which depend on the difference in specific gravity between the suspended water and the steam. In the latter case, ordinary practice involves a ratio of specific gravities of the order of 150 to 1, whereas in the case of removing ammonia from the high pressure gas the ratio is but one-tenth as great. In view of the low specific gravity ratio, high velocities are probably essential in mechanical separation. Other requirements, no doubt, are low friction of the gas stream over the separating surfaces, and immediate removal of the separated liquid from contact with the gas. All the above has been kept in mind in the development by the Nitrate Division of an ammonia separator for use at Sheffield should the plant ever again operate.

The Germans, in developing their process, had seriously considered and experimented with refrigeration as a means of ammonia removal, but they finally turned to water absorption as the easiest solution of the problem. In so doing, they gave up several distinct advantages of refrigeration: (1) Circulation of pure dry gases in which desiccation is maintained by the precipitation of anhydrous ammonia within the gas.

(2) Production of pure anhydrous ammonia is accomplished without any further steps of distillation. The first of the above is the most important in view of the fact that moisture in the system decreases catalytic activity and reduces the capacity of the entire installation, as has been previously discussed. The second is important only in connection with the utilization of the ammonia. On the other hand, water absorption of ammonia has the advantage of practically complete ammonia removal, and decided reduction in power consumption.

Circulating System at Oppau

The gas is circulated through the converter sets and through the absorption system by 10 double-acting circulating pumps. These are steam driven and direct connected at 90 deg; the pump cylinder is vertical and the steam cylinder horizontal. In normal operation the differential pressure necessary to circulate the gases is about 5 atmospheres, though it has, at times, risen to 10. The circulating pumps are located in the cycle just after the absorbers and ahead of the converter sets. At the inlet side of the circulating pump the pure make-up gas is added and also the composition of the gas in circulation is adjusted by the addition of the pure nitrogen that was spoken of earlier in this paper.

The question frequently arises as to whether it is desirable to have the circulating pump precede or follow the point in the system where the make-up gases are added. In the latter case, the pump must directly handle the volume of make-up gas, together with the volume of circulating gases. However, the total pressure of the circulating system is higher by the amount of the differential pressure, since the pressure of the make-up is fixed by the pressure of the purification system. The pressure desired in the circulating system should determine the location of the circulating pump; the total quantity of energy expended is but slightly different in the two cases.

The speed of circulation of the gases as it affects the catalysis of the ammonia has been discussed in connection with space velocity under ammonia synthesis. For a given installation, operation may develop any one of the following limitations to increase the speed of circulation: (1) Insufficient heat transfer to maintain the temperature of the ammonia converter sets, (2) insufficient capacity of the purification system to supply the necessary gas for the increased yield, (3) insufficient capacity of the ammonia-removal installation to take care of the increased yield, and (4) excessive friction to gas flow in the apparatus of the circulating system. These general engineering aspects of the process are of fundamental importance, but their discussion is not within the purpose of this paper.

Inert Gases

The inert gases, methane and argon, are present to the extent of 0.5 to 0.7 per cent in the make-up entering the circulating system at Oppau, and tend to accumulate as the hydrogen and nitrogen are being removed in the form of ammonia. Some method of removal of this accumulation must be employed. The simplest method for continuous operation is to allow a fraction of the circulating gases to escape continually. Purging a quantity of gas from the circulating system equivalent to 5 per cent of the entering make-up gas will maintain a concentration of inert gases of 20 times that in the make-up. Likewise, 10 per cent purge will allow a concentration of 10 times that entering the system. The effect of inert gases on the catalysis of ammonia is very decided due to the lowering of the equilibrium, but on the other hand, the loss of purified hydrogen and nitrogen in the purge is costly, although the hydrogen may be burned under boilers. In operation the choice as to the proper purge is generally fixed by the unavoidable leakage in the system. Thus, at Oppau, this was never below 10 per cent of the makeup gas, therefore the concentration of the inert was never above 5 to 7 per cent and no additional purge was necessary.

Circulating System at Sheffield

At Sheffield the gas exit from the liquefiers passed to the circulating pumps, the make-up gas connecting in at the exit of the pumps. The circulating pumps themselves were vertical, double acting, motor driven, but due to the sensitiveness of the catalyst, were not lubricated and therefore not equipped with piston rings.

This led to rather low volumetric efficiency. The pumps had been designed for a maximum differential of 50 lb. Due to the many right-angle elbows and tees, numerous valves, and the special construction of the heat interchangers, the friction in the system accumulated to 150 lb. and still less gas was circulated than was necessary. This caused considerable difficulty with the pumps and their motors. Engineering experience offers very little information for the calculation of friction of gas flow under the conditions existing in the synthetic ammonia process. Some preliminary experiments conducted by the Nitrate Division indicate that it varies with the square of the velocity and therefore that a formula of the standard type may apply.

There are no facilities for adjustment of composition in the circulating system at Sheffield, but during operation such adjustment was found unnecessary in view of the high losses, which at times amounted to 50 per cent. These losses of course prevented accumulation of either hydrogen or nitrogen in the system, as well as accumulation of the inert gases.

The pipe connections throughout the system were all made up with copper gaskets, which worked very satisfactorily where there were no undue strains on the joints. The apparatus in the circulating system was arranged very closely and there was no allowance for the expansion due to the extreme range of temperature. The strain thus set up always developed leaks. There were many valves in the heat interchanger connections and in other hot parts of the system and although these valves were water cooled, still the differential expansion between the stem and the block caused difficulties. Operation on this portion of the system was, however, so intermittent and of such short duration that no opportunity was given to cure the difficulties encountered, although the matter has been taken up with great care in the redesign of the plant and in the development of joints and valves.

The last installment of this article, in which the costs of construction and production at Oppau and Sheffield are compared, will be published in a subsequent issue.

Heat Balance in Coal Distillation

An investigation to determine the amount of heat evolved or absorbed through chemical reaction in the destructive distillation of coal is being conducted by the Bureau of Mines. Such information will give the by-product coking and gas industries a more accurate knowledge of the thermal requirements of their ovens and retorts.

Explosion-Proof Process of Solvent Recovery

Descriptive Study of Lewis Recovery System in Which the Explosion Hazard Is Eliminated by Using Cleaned Flue Gas as the Drying Medium—Theoretical Consideration of the Relation Between Recovery and Recirculation in the Condensation-Recirculation Process

By B. F. DODGE
Chemical Engineer

ONE of the strongest objections to the use of flammable solvents in industrial operations and to most of the solvent recovery processes is the fire and explosion hazard. In many of the processes proposed or utilized in the past an attempt has been made to keep the average concentration of the solvent vapor in the air-vapor mixture outside of the explosive range. This is generally unsatisfactory and many such attempts have resulted in disaster. To keep the concentration below the explosive range means that a large amount of gas must be handled which is very dilute in solvent vapor. It is well known that the installation costs and operating costs of a recovery plant increase rapidly as the concentration decreases. Furthermore, unless extreme care is exercised in the design of the ventilating equipment, pockets are apt to form where dangerous concentrations are present. On the other hand, attempts to work above the explosive range almost always result in failure, because it is inevitable that somewhere in the recovery plant the explosive range is being passed through and furthermore the explosive range must be crossed in starting or stopping the operation by which the drying of the goods is performed.

It has long been recognized that this hazard could be overcome by replacing the air as a carrier by some inert gas such as nitrogen or carbon dioxide. The cost of producing such a gas, however, has militated against its use. This objection has been met by a process developed by Dr. W. K. Lewis of the chemical engineering department of the Massachusetts Institute of Technology, who has used a cleaned flue gas as the inert drying medium. Lewis pointed out that it is only necessary to remove part of the oxygen from the air to make a good inert gas, and the simplest way to remove oxygen from air is to allow the oxygen to react with carbon or hydrocarbons as in an ordinary combustion reaction. Consequently, by the term "flue gas" is meant any gas produced by depleting the oxygen of the air by reaction with carbon or hydrocarbons.

Before referring to the process itself, it may be well to discuss briefly the flammability of gas mixtures, in order to show that the presence of flue gas prevents explosion even though a considerable percentage of oxygen may be present.

Limits of Flammability of Gas-Air Mixtures

It is a well-known experimental fact that mixtures of so-called flammable gases with air are only flammable between certain definite concentration limits. This does not mean of course that they will not burn if heat is continuously supplied from an external source, but rather that they will not support combustion of themselves. The experimental determination of the upper and lower limits is difficult because of the many factors involved. The results that appear in the literature vary, but in Table I are given the limiting values for some common gases, expressed as volume per cent of the gas.[1]

TABLE I—FLAMMABILITY LIMITS OF SOME COMMON GASES AND VAPORS, EXPRESSED AS PER CENT BY VOLUME.

Gas	Lower Limit	Upper Limit
Hydrogen	8.5— 9.5	66.3—75.5
Methane	5.5— 6.3	12.7—13.5
Ethylene	3.4— 4.1	14.5—14.6
Ether	1.6— 2.8	7.5— 7.7
Alcohol (C_2H_5OH)	3.7— 4.0	13.6—13.7
Benzene	1.4— 2.5	6.3— 6.5
Pentane	1.3— 2.4	4.8— 4.9
Carbon monoxide	14.3—16.5	74.0—75.0

Oxygen is, of course, necessary for the explosion of a gas mixture, and consequently explosions can be entirely prevented by replacing the oxygen by some inert gas such as carbon dioxide, carbon monoxide, nitrogen or mixtures of them. A very important corollary of this is that it is only necessary to replace a part of the oxygen to obtain a non-explosive mixture and the permissible per cent of oxygen is surprisingly large. For example, it is found experimentally that, with a mixture of methane and air, if the oxygen is reduced to 13 per cent by replacing part of it with carbon dioxide, no ex-

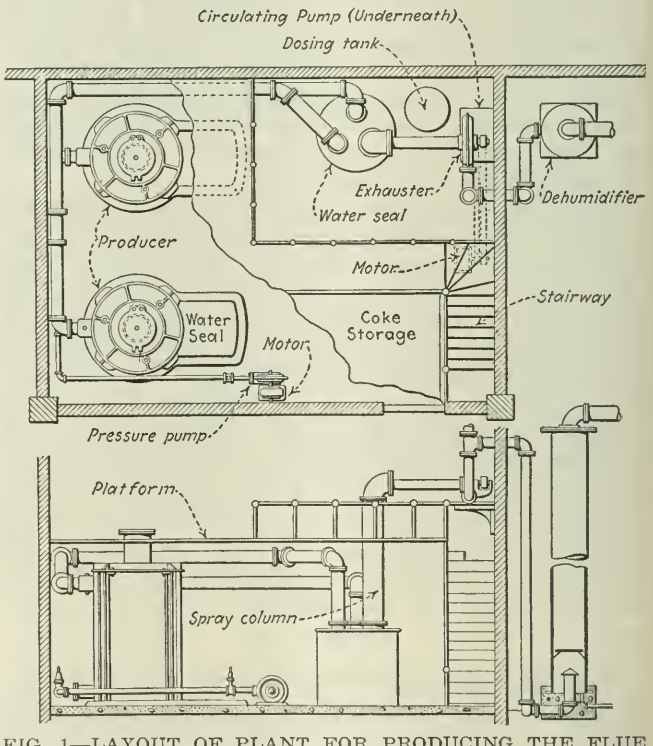

FIG. 1—LAYOUT OF PLANT FOR PRODUCING THE FLUE GAS FROM COKE

[1] "Untersuchungen über die Explosions Grenzen brennbarer Gase und Dampfe"—Paul Eltner.

plosive mixture is possible with any percentage of methane. On the basis of the theory of flammable limits, we are able to calculate the permissible per cent of oxygen for a number of gases. Without going into the details of the theory it may simply be stated that no explosive mixture of gasoline or of benzene and air is possible if the oxygen is maintained below about 12 per cent.

Producing the Inert Gas

The inert gas is cheaply produced by burning coke in a special type of producer or by burning fuel oil in a small brick oven. The gas from the producer or oven, consisting mainly of carbon dioxide, nitrogen and water

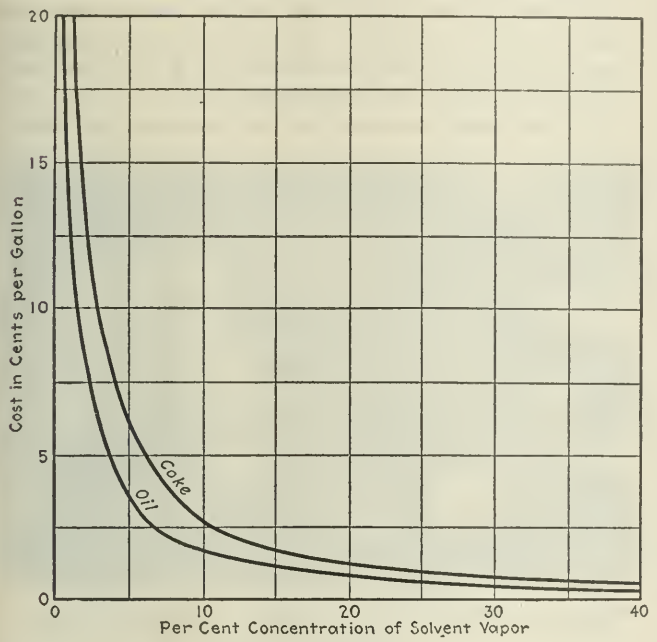

Fig. 2—Relation Between Cost of Fuel for Flue Gas (expressed as cents per gallon of solvent recovered) and the Concentration of the Solvent Vapor (expressed as volume per cent).

vapor, is cooled, cleaned and dehumidified in a spray chamber or coke tower, after which it is ready for use as the solvent drying medium. If the oil or coke is high in sulphur, it may be necessary to include a scrubbing outfit to remove sulphur dioxide. The choice between coke or oil is largely an economic question depending on their relative cost, as either will yield a clean gas of low oxygen content (0 to 2 per cent). Fig. 1 shows a layout of a plant for producing the gas using coke as the fuel.

The reaction of air with coke can be controlled to produce either carbon dioxide or carbon monoxide as desired. In producer gas practice, carbon monoxide is the main product desired, but for use as an inert gas, carbon dioxide is the more desirable. A study of the equilibrium relations among carbon, carbon dioxide and carbon monoxide and of the rates of reaction shows that the conditions for maximum carbon dioxide production are low temperature of the fuel bed, a shallow bed (as shallow as is consistent with no air holes) and a fairly low velocity of gases through the bed. The producer should be set in an iron shell to reduce the inward leaking of oxygen if run under suction, or outward leakage of gas if under pressure. With proper design of the producer and proper control of the firing and draft, a gas can be consistently produced that contains 18 to 20 per cent of CO_2 and 0.1 to 1.5 per cent of O_2.

The use of flue gases from an ordinary boiler is not desirable because of the high and fluctuating oxygen content and the presence of soot, which is difficult to remove in a simple manner. The use of coke gives a gas that is practically free from finely divided solid or liquid particles, and an oil burner can be operated in such a way as to give a clean gas with a low oxygen content. In small installations the recovery of the heat in the flue gases does not pay, but for large installations it is sometimes advantageous to generate the flue gas in a coke-fired or oil-fired boiler, although bearing in mind that the primary object is the generation of the inert gas.

It can readily be calculated that 1 lb. of coke and 1 gal. of fuel oil will yield about 120 cu.ft. and 1,600 cu.ft. respectively of dry gas at 70 deg. F. The cost of the flue gas per gallon of recovered solvent is a function of the concentration of the solvent vapor that can be obtained in the gas, and since the latter is relatively high in most cases, the cost is practically negligible. Fig. 2 gives a comparison of calculated fuel costs to produce the gas, assuming coke at $18 a ton and fuel oil at 7c. a gallon. The cost can be reduced and the recovery increased by the simple expedient of recirculating part of the flue gas from the recovery plant.

Application to Various Processes of Solvent Recovery

The gas may be applied to any compression, refrigeration or absorption process of solvent recovery without any change in the recovery equipment. The recovery obtained is just as high as when air is used as the medium.

In using flue gas it is necessary that the drying operation be carried out in a well-inclosed space so that

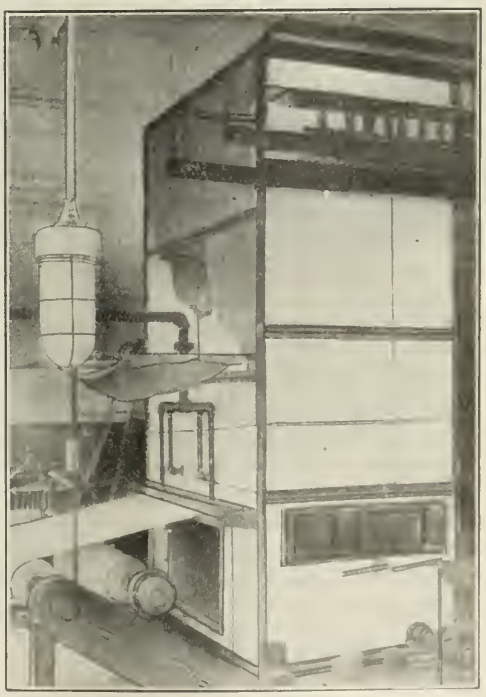

FIG. 3—HOODED IMPREGNATOR FOR CORD TIRE FABRIC IN ACTUAL USE

leakage of air in, or of the flue gas out, will be a minimum. This has led to the development of efficient hoods for various machines in which solvent is used, with the result that greater production has been attained, the operators are effectually shielded from the injurious ef-

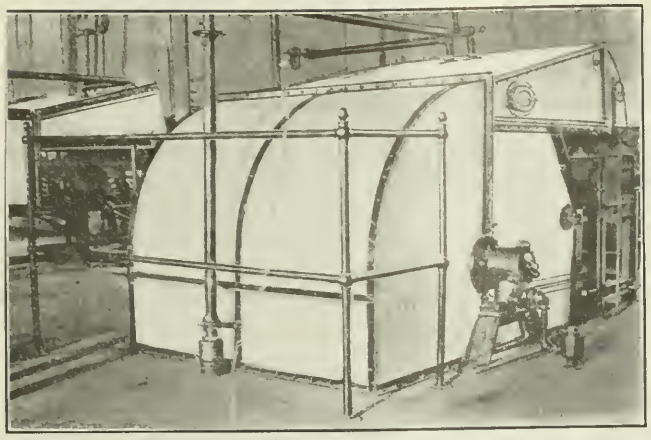

FIG. 4—DRUM SPREADER EQUIPPED WITH HOOD FOR USING FLUE GAS PROCESS OF RECOVERY

fects of solvent fumes. Furthermore, the better control of the drying conditions results in a more uniform product. To treat further of this very important phase of solvent recovery is beyond the scope of this article. Attention is called, however, to Figs. 3, 4 and 5. Fig. 3 shows a hooded impregnator for cord tire fabric and Figs. 4 and 5 show the types of hoods that have been applied to drum and flat spreaders used for the rubberizing of fabrics. Figs. 4 and 5 are rear and front views respectively of a hooded drum spreader.

Condensation-Recirculation Process Using Flue Gas

The method of solvent recovery based on condensation in a water-cooled condenser followed by recirculation of the gases leaving the condenser to the point where the solvent is being evaporated can be shown to possess a number of advantages, particularly as regards initial cost of equipment and operating and maintenance charges. The commercial development of this method has been retarded by two factors—viz., (1) the difficulty of obtaining sufficiently high concentrations, and (2) the fire and explosion hazard. The first difficulty has been met by the design of efficient hoods as discussed above, and the second by the use of flue gas as the carrying medium for the solvent vapors.

With a recirculation system of this type it is impossible to recirculate all the gas leaving the condenser, if the solvent-using operation is a continuous one, because small leaks will occur where the material being treated enters and leaves the drying chamber. In the development of this process the main problem was to determine if enough of the gas could be recirculated to give a high recovery without allowing the oxygen content to become high enough to introduce any explosion hazard. This process was first studied from a theoretical standpoint and found to be feasible, after which the theory was substantiated on a plant scale.

A study of the effect of inert gas on the flammability of gas mixtures established the fact, as previously shown, that there was no explosive mixture of benzene or of gasoline possible if the oxygen content was reduced to 12 to 13 per cent. To allow a factor of safety, it was decided to limit the oxygen to 5 to 6 per cent in the gas entering the drying chamber.

In a recirculation system of this type an equilibrium

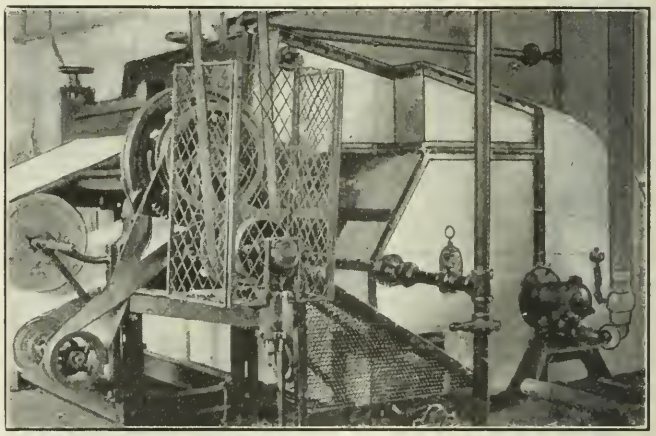

FIG. 5—ANOTHER VIEW OF HOODED DRUM SPREADER IN USE

oxygen concentration will be attained when just as much oxygen is being purged from the system in a unit of time as is entering the system. Consequently, the main factors affecting the per cent of permissible recirculation will be the amount of leakage in or out of the system, the amount of oxygen in the fresh "make-

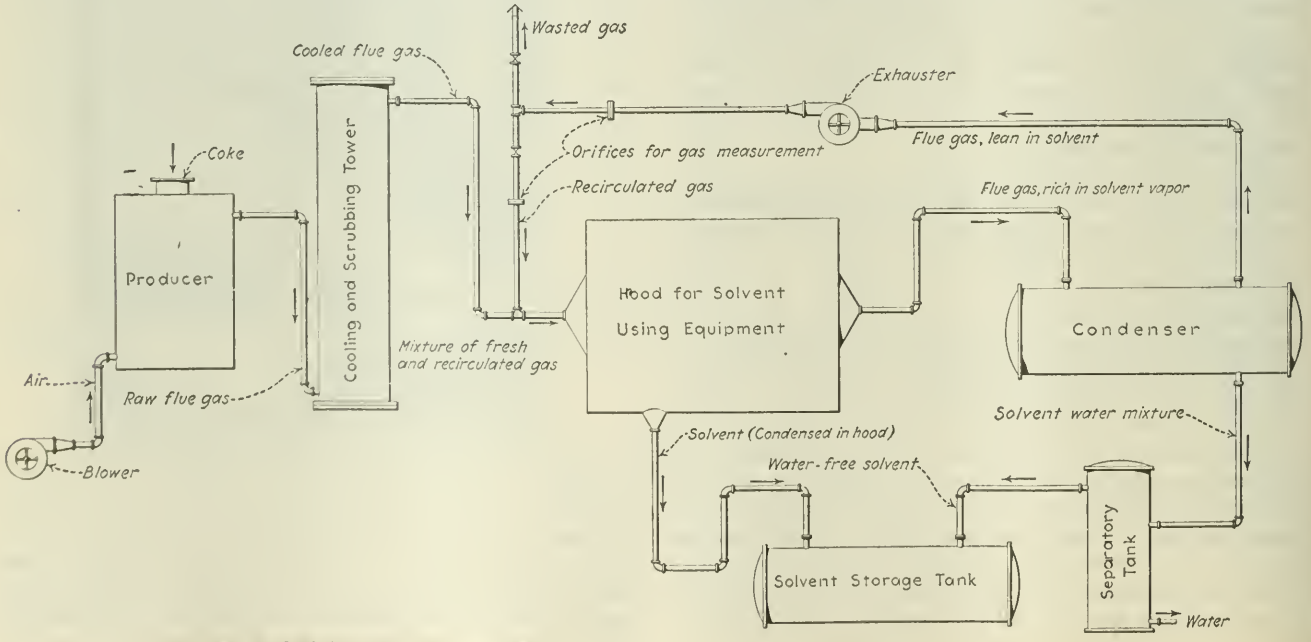

FIG. 6—FLOW SHEET OF CONDENSATION-RECIRCULATION PROCESS USING FLUE GAS

up" flue gas, and the permissible oxygen in the system. All the leakage will occur in the hooded drying chamber and the assumption was made that practically all the leakage was inward. On this basis a general equation for recirculation may be developed. Reference to the flow sheet of the process, shown in Fig. 6, will aid in understanding the factors involved.

Developing an Equation for Recirculation

Solvent is being evaporated under a hood, which is assumed for sake of illustration to be inclosing an equipment for impregnating a fabric with a rubber compound. Some air leaks into the hood at the point of entrance and exit of the fabric. The flue gas, rich in solvent, goes to the condenser, where part of the solvent is condensed. The gas, now lean in solvent but containing very appreciable amounts, divides, as shown, into two portions. One portion is recirculated back to the hood, receiving an addition of fresh flue gas as shown, and the other portion is wasted to the atmosphere. It is desired, of course, to recirculate as great a fraction of the gas from the condenser as possible, but this is limited by the leakage and the permissible oxygen content. The following quantitative treatment of the problem was a valuable aid in predicting the result of large-scale experiments:

Let f = fraction of the gas recirculated.
O_r = fraction of oxygen in the recirculated gas.
n = mols of air leaking into the hood per mol of total gas fed to the hood.
O_g = fraction of oxygen in the fresh flue gas.
S = fraction of solvent in the gas leaving the condenser.
m = mols of gas leaving the condenser per mol of gas fed to the hood.

Then, on the basis of 1 mol of total gas fed to the drying chamber,

mfO_r = mols oxygen recirculated.
$mO_r(1 - f)$ = mols oxygen purged from the system.
$(1 - mf)$ = mols fresh flue gas.
$O_g(1 - mf)$ = mols oxygen entering with the fresh flue gas.
$\frac{n}{5}$ = mols oxygen leaking in.

Equating the input and output of oxygen we obtain:

$$\frac{n}{5} + O_g(1 - mf) = mO_r(1 - f) \qquad (1)$$

m is best expressed as a function of the other factors in the following manner:

In m mols of gas leaving the condenser there are $(1 - s)m$ mols of non-condensible gas which is made up of the non-condensible gas recirculated, plus the air leaking in, plus the fresh flue gas.

In the mf mols of gas recirculated, there are smf mols of solvent. Therefore, there are $(1 - smf)$ mols of non-condensible gas entering the drying chamber.

Equating the non-condensible gas leaving the condenser to that leaving the drier, we obtain:

$$(1 - s)m = 1 - smf + n$$

or,

$$(1 - s)m + smf = 1 + n$$

and,

$$m = \frac{1 + n}{1 - s + sf}$$

Substituting this value of m in (1), the equation becomes

$$\frac{n}{5} + O_g\left[1 - \frac{f + fn}{1 - s + sf}\right] = \frac{O_r(1 - f)(1 + n)}{1 - s + sf}$$

Solving for f, we obtain:

$$f = \frac{O_r + O_r n + O_g s - O_g + \frac{ns}{5} - \frac{n}{5}}{\frac{ns}{5} + O_g s - O_g - O_g n + O_r + O_r n} \qquad (2)$$

The approximate value of the per cent recirculation for a wide variety of conditions can be predicted by substituting in this equation. It is found, in this way, that a fairly large percentage variation in the oxygen content of the fresh flue gas has only a small effect on the recirculation whereas variation in the leakage seriously affects the recirculation.

Table II gives the results of some calculations made with the aid of equation (2).

TABLE II—PERCENTAGE RECIRCULATION AND PERCENTAGE RECOVERY CALCULATED FOR DIFFERENT VALUES OF O_r AND n

Case I. $n = 0.10$, $O_g = 0.01$, $S = 0.12$, O_r variable				Case II. $O_r = 0.05$, $O_g = 0.01$, $S = 0.12$, n variable			
$O_r \times 100$	$f \times 100$	Per Cent Recovery A*	Per Cent Recovery B†	$n \times 100$	$f \times 100$	Per Cent Recovery A	Per Cent Recovery B
2	0	70	20	2	91	97.3	92.8
3	27	78.1	41.6	5	79	93.7	83.2
5	60	88.0	68	10	60	88.0	68.0
7	73	91.9	78.4	20	30	79.0	44.0
10	82	94.6	85.2	25	17	75.1	33.6

*The concentration of solvent vapor is assumed to be such as to give a 70 per cent recovery by simple condensation without recirculation.
†The concentration of solvent vapor is assumed to be such as to give a 20 per cent recovery by simple condensation without recirculation.

Referring to Case I in the table, it is seen that the percentage recirculation is greatly influenced by the allowable percentage of oxygen in the recirculated gas, increasing rapidly as the oxygen is raised. If the concentration of solvent vapor is high, say over 35 per cent, the percentage recovery is good even with a small recirculation, but if the concentration is as low as 15 per cent a higher percentage recirculation must be maintained to obtain a good recovery.

Case II shows the effect of leakage on the percentage recirculation, the other factors being fixed. As would be expected, the allowable percentage recirculation ($f \times 100$) becomes rapidly lower as the leakage increases. This in turn affects the recovery, and again the effect is much more marked for the case of low concentration of solvent vapor (B) than for the case of high concentration (A). It is obvious that the process can be applied only to cases where concentrations of solvent vapor may be obtained that are appreciably greater than the equilibrium concentration at the temperature at the exit of the condenser, which means that the solvent must be evaporated at a temperature well above room temperature.

In one case to which this process was to be applied —namely, the impregnation of cord tire fabric—O_r was chosen to be 0.05 (5 per cent of permissible oxygen in recirculating gas), n was assumed to be about 0.1 on the basis of the leakage tests that were available, O_g could easily be kept to 0.01 and s was about 0.12. Substituting these values in equation (2), $f = 0.60$. In other words, 60 per cent recirculation could be used under these conditions. Inasmuch as about 80 per cent recovery is obtained in the simple condenser without recirculation, the total recovery with recirculation should be $80 + (0.60 \times 20) = 92$ per cent, or nearly as much as could be obtained with a more complicated equipment. It was found in actual practice that between 60 and 70 per cent recirculation could be used under approximately these conditions, thus bearing out the value of the preliminary theoretical study. The leakage is actually less than 0.1 on the average, and it seems probable that about 75 per cent to 80 per cent recirculation can be used with a well-designed hood.

Lewis Recovery Corporation,
Cambridge, Mass.

Legal Notes

By Wellington Gustin

Chemical Company Liable for Death of Horses Where It Filled Dedicated Street With Refuse

In the action by Harry Shapiro against the Albany Chemical Co., it was shown that the chemical company had dumped a tarry and caustic material into the street adjoining its property in such a manner that its nature was not apparent. The plaintiff's horses, while being driven along such street, became mired in the material, where it had a depth of about 5 ft., causing the death of the animals. The company was sued for negligence and damages were recovered. (189 N. Y. S., 736.)

On appeal the Appellate Division of the New York Supreme Court confirmed the company's liability. It says where a city extended its conduit through a street, dedicated as a public street but never accepted as such, with consent of the chemical company abutting thereon, and not claiming to own the street, which extension involved the use of the street to a greater or less degree, the company, which filled the street with a tarry and caustic material carried in a pipe from its works, is liable to an employee of the city for death of his horses, which became mired in such material when he was directed to go on the premises and remove a pump. The company was under obligation to exercise its right in the street consistently with the fact that it had been dedicated for public use, and that title to adjoining property had passed on the strength of that condition.

Circuit Court of Appeals Affirms Decree Holding Wooster Patent No. 933,011 Void

The United States Circuit Court of Appeals recently affirmed the decree of the District Court in the matter of the Duryea Manufacturing Co. vs. Agrippa Manufacturing Corporation and others, whereby the Wooster patent, No. 933,011, was held void for anticipation by the old Pearce & Beardsley patent by about 25 years. (273 Fed. Rep., 522.)

After a period of experiments the Duryea Co. produced a woven cotton belting which it saturated with a solution of asphaltum and placed upon the market with very favorable results. A patent covering the belting was issued in 1909. In 1917 or 1918 the defendant corporation began to manufacture a similar product and placed it on the market, and plaintiff asked that defendant be enjoined and give an accounting.

The defense was that defendant used the old Pearce & Beardsley patent of 1886, No. 348,993, in the manufacture of its product.

The claim of the Wooster patent is for belting consisting of an absorbent woven fabric body portion which has been saturated with a solution of asphaltum and dried. The old Pearce & Beardsley patent was for a new article of manufacture of all kinds of cloths and fabrics other than for paper and treated with a compound of bisulphide of carbon and maltha substantially as set forth in the patent.

Maltha is described as a soft asphalt, and proof showed that the process of saturating as described by Pearce & Beardsley and the saturation under pressure described by Wooster are substantially the same. The earlier patent describes the process of manufacture with almost the same degree of exactness as that of the plaintiff's patent. True, there had been no general marketing of the product under the first process, but the court said the proof of manufacture under this patent, though slight, indicates a disclosure to the world and made such patent more than a prophetic suggestion, as was urged by plaintiff. Plaintiff's only act beyond the patent of Pearce & Beardsley was the creation of a market for its output, but, says the court, this fact alone, standing by itself, cannot be a ground for sustaining the validity of its patent, which discloses nothing new to the world except the idea of pressure to obtain "saturation," which is obviously only one of a number of means of accomplishing the results.

Contracts of c.i.f. Shipments Construed

In an action by Willets & Patterson against Abekober & Co., Ltd., the plaintiff was a California corporation and defendant was a Japanese corporation. The latter sold the former 750,000 lb. of soya bean oil, payment in full being made for same, but when the oil arrived in San Francisco there was a shortage of 79,555 lb. The purchaser then brought this suit to recover back the proportionate amount of the purchase price paid. (189 N. Y. S., 525.)

Upon an appeal in the case by the plaintiff to the Appellate Division of the New York Supreme Court the sole question presented for determination was whether the plaintiff had shown the existence of the cause of action as set forth in his pleadings, which was an action upon the contract. The trial court held that this contract was simply a c.i.f. contract, and that the perils of the voyage from Japan to San Francisco were at the buyer's risk, and for failure to show that this shortage existed at the time of the delivery to the carrier the plaintiff had failed to show any right of action.

The higher court says the law is well settled that a simple c.i.f. contract requires the seller to deliver to the carrier, and upon such delivery the obligation of the seller is at an end, and the risk is thereafter with the buyer. However, it says these contracts of sale are to be construed according to the intention of the parties to the contract. A straight f.o.b. contract is satisfied by the seller's delivery to the carrier for the purpose of shipment, the risk of transportation resting upon the buyer. If, however, there be anything in the contract which shows that such was not the intention of the parties, the contract will be construed according to their intention.

Intention of the Parties

This same court earlier held, in the case of Standard Casing Co., Inc., vs. California Casing Co. (188 N. Y. S., 358), that in a contract to ship from California to New York, reserving the right of inspection to the buyer at New York, the liability of the seller was shown by this provision to extend to a delivery in New York City, notwithstanding the contract provided for a price f.o.b. San Francisco. In yet another case it was held, notwithstanding a named price f.o.b. at point of shipment, that the right of inspection at the destination of the transportation indicated an intention that the delivery was not to be deemed complete until such destination was reached. Other facts or circumstances may show the intention of the parties.

In the case at bar the sale contract contains the provision "net landed weight." The court construed this to mean the weight at San Francisco must accord with the contract requirements as to weight.

Technical News of the Week

Current Events in the Chemical, Metallurgical and Allied Industrial Fields—Legislative Developments—Activities of Government Bureaus, Technical Societies and Trade Associations

American Electrochemical Society Announces Spring Meeting Plans

A tentative program for the spring meeting of the American Electrochemical Society which is to be held in Baltimore, Md., April 27 to 29, has been announced. Headquarters will be established at the Hotel Emerson. The technical sessions will be held Thursday, Friday and Saturday mornings and will include three symposiums: Electric Furnace Cast Iron, Gases of the Electrochemical Industries and Electromotive Chemistry. By "electromotive chemistry" is meant that branch of electrochemistry which has to do with the production of electromotive forces by means of chemical processes and in a broader sense would include related phenomena as the "photo-electric effect," and allied electronic effects. On the theoretical side, papers on the electrolytic theory of oxidation and reduction, on concentration cells of various types, on potentials at liquid junctions, electrical phenomena in living protoplasm and on the electron theory may be expected. On the industrial side, the practical application of the theoretical aspects of the subject and in particular papers on primary and secondary batteries should provide material for discussion.

The plans under way provide for visits to industrial plants, a complimentary smoker to be given by the chemists and engineers of Baltimore, a golf tournament, a boat trip, an illustrated lecture by Prof. W. R. Wood on "Fluorescence" and an entertainment program for the ladies.

Mysterious Explosion Causes Casualties and Fire at Zapon Plant

The explosion of a tank car supposed to contain mixed acid caused the death of two operators and started a fire which destroyed two of the storage warehouses at the plant of Richards & Co. in Stamford, Conn., on Feb. 24. The Stamford plant is the home of Zapon artificial leather and the lacquer works of Richards & Co.

According to Edward D. Williams, superintendent of the plant, the car of acid, which had been received recently from an acid plant in New Jersey, had been spotted and connected to the line leading to storage tanks. The two operators had phoned to the acid office to have the air turned on the car. Apparently, the explosion occurred just after the air was turned on, although this can never be definitely established. The car sample was destroyed in the explosion so that the analysis of the acid is unknown. Mr. Williams and other plant officials could offer no explanation as to the cause of the accident.

The fire which followed the explosion destroyed two warehouses containing cotton linters, pigments, shipping containers and miscellaneous supplies. Plant officials expect to be operating normally inside of a week.

Patent Office Relief Assured

The President signed the Patent Office relief bill on Feb. 18. Since the bill carries only the authorization for the appropriation, the reorganization and installation of additional personnel must await the actual granting of the money. It is probable, however, that the appropriation can be carried in a forthcoming deficiency bill. The change in patent fees does not become effective until April 19.

Farmers Unite in Protest on Potash Duty

Senator McLean of Connecticut has presented to the Senate a petition of 25,000 New England farmers protesting against a duty on potash.

New Committee Finally Begins Hearings in Long-Delayed Dye Investigation

The initial sessions of the hearing on the Senate resolution calling for investigation of certain activities on the part of domestic dye manufacturers and on the part of importers of foreign-made dyes were devoted largely to a repetition by Senator King of the various charges made by him heretofore in the Senate. He also has covered most of the points made by former Senator Thomas, whose mantle Senator King has assumed. The du Pont Co., the Chemical Foundation and the Textile Alliance were given special attention.

When the committee met for its first hearing, Senator Reed stated that he found it would be impossible to give any time to the investigation. Senator Ernst of Kentucky also was excused from serving. He explained that his law firm is counsel for the Grasselli Chemical Co. and that while he is of the opinion that he could serve without prejudice, he pointed out that the connection was likely to be a source of embarrassment, not only to him but to the sub-committee. This made it necessary for Senator Shortridge of California, the chairman of the sub-committee, to lay the situation before the Judiciary Committee and request the assignment of two of its members to sit with him in the conduct of the investigation. Senator Sterling of South Dakota and Senator Ashurst of Arizona were designated and are sitting with Senator Shortridge.

Frelinghuysen Defends Dye Industries

The delay in getting the investigation started rather nettled Senator Frelinghuysen of New Jersey, who pointed out vigorously that charges are resting over the head of an American industry and that it is entitled to the prompt consideration of its side of the case, if it is not to be handicapped in its contest with the German monopoly which is seeking to dominate the American market. Senator Frelinghuysen demanded, in effect, that Senator Moses of New Hampshire be called upon to prove the charges which he had made against the American dye industry. He promised to lay before the committee evidence as to the activities of the representatives in this country of the German trust and of importers. He said the domestic industry had been built up not only to save the domestic textile industry during the war but to enable the Allies to overcome Germany's initial superiority in chemical warfare. "Germany nearly won," said Senator Frelinghuysen, "by reason of our lack of vision and statesmanship in failing to protect the American dye industry."

The Position of the Textile Alliance

An important statement was made to the committee by F. R. Coudert, attorney for the Textile Alliance. Extracts from his statement follow:

"The Textile Alliance, Inc., is a New York State, non-profit, membership corporation, whose voting members and directors are nominees of trade associations representing practically the entire textile trade of the United States.

"In October, 1919, and several times since the Textile Alliance, Inc., without solicitation on its part, was requested by the Department of State to undertake—and it did undertake—the purchase and distribution of reparation dyes accruing to the United States.

"In October, 1921, a protest was filed with the Department of State against the continuance of this arrangement by Kuttroff, Pickhardt & Co., Inc., a New York corporation, owned and managed by American citizens of German birth, who formerly in their corporate or private capacities were agents of the Badische Anilin- & Soda-Fabrik, one of

the six constituent members of the German dyestuff monopoly. The State Department on Dec. 14, 1921, abrogated the arrangement with the Textile Alliance, Inc., stating that there was no dissatisfaction with the work of the Alliance and that there was no objection by the department to the Reparation Commission continuing the allocation of reparation dyes to American non-profit organizations. Later, letters were given by the department to Kuttroff, Pickhardt & Co., Inc., and to other former representatives of the German dye monopoly, stating that the department had no objection to the Reparation Commission allocating reparation dyes to them.

"As a result the Reparation Commission refuses to continue to supply reparation dyes to America until the Department of State shall decide who the recipients of the American portion shall be.

"If the allocation be divided among profit-seeking corporations connected or formerly connected with the German monopoly, the effect will inevitably be to re-establish the control, not only of reparation dyes but of all German dyes, in the hands of the German monopoly or those representing it.

"The Textile Alliance, Inc., does not seek to continue this work itself and would prefer to have it in the hands of a government department."

Expert Testimony to Be Called

Senator King filed a list of names with the committee asking that each be subpœnaed to appear and to produce books, papers and correspondence and accounts. Among those included in the list are Thomas O. Marvin, chairman of the U. S. Tariff Commission; Julius Klein, director of the Bureau of Foreign and Domestic Commerce; General Amos A. Fries, chief of the Chemical Warfare Service; H. E. Howe, formerly chief of the National Research Council; Charles L. Parsons, secretary of the American Chemical Society; B. R. Price, National Aniline Co.; E. A. Mason and F. L. Fleisch, Textile Alliance, Inc.; Charles H. Herty, president Synthetic Organic Chemical Manufacturers' Association; R. C. Jeffcott, president American Dyes Institute; Samuel Iserman, Chemical Company of America; Irenee du Pont and other representatives of the E. I. du Pont de Nemours & Co. and of the Allied Chemical & Dye Corporation.

Faults in Design, Not Materials, Caused Collapse of R-38

That the accident which wrecked the giant dirigible R-38 at Hull, England, Aug. 21, 1921, was caused by structural weakness in the design of the airship rather than defects in structural material is shown by the report of the Aëronautical Research Committee to the British Air Ministry. The report admits the presence of a certain amount of softened duralumin in the airship, but insists that faulty material did not contribute to the accident. In a summary of its conclusions the committee says that it has reached the following conclusions:

1. That the accident was due to structural weakness in the design of the airship.
2. That during the final flight no loads were imposed in excess of those which might have occurred during the normal navigation of the ship in weather which might reasonably be encountered.
3. That, having regard to her size and speed, R-38 was considerably weaker than R-33.
4. That the provision of specially powerful control surfaces of new design virtually accentuated this weakness.
5. That no calculations were made of the stresses due to the aërodynamic forces to which the ship would be subjected.
6. That in consequence, the calculations made by the design staff, taking specific account only of the forces and movements due to the distribution of weight and buoyancy, including gas pressures, were misleading.
7. That, owing to instability of the ship, combined apparently with overbalance of the control surfaces, the movements of the controls necessary to keep the ship on any particular course were comparatively larger.
8. That the structure was not improbably weakened by the cumulative effect of reversals of stress of magnitude not far short of the falling stress.
9. That for the progressive development of airships in size and speed reference to first principles in design is necessary, and that it is not sufficient to place exclusive reliance on comparison with existing ships.
10. That the existing methods of calculation at present in use for determining the scantlings of structural members of an airship are insufficiently accurate for this purpose and that more exact methods, the outline of which can at present be indicated, should be developed.
11. That research by both model and full-scale experiment is essential to determine and verify the forces to which an airship is subjected.
12. That the terms of the requirements laid down in time of war for R-38 were extremely drastic and that the limitations involved by the size of the shed in which the airship had to be built imposed too severe a task on the designers.
13. That at the time when the design was originally laid down information as to aërodynamic forces existed which should have led to a more detailed consideration of the effects of these forces and to consultation with the Advisory Committee for Aëronautics as to the dangerous loads foreshadowed by the early model experiments on aërodynamic pressures.
14. That in spite of the presence of a certain amount of softened duralumin in the airship, faulty material did not contribute to the accident.
15. That on the assumption made, the structure was designed with great skill and the necessary calculations were carefully carried out by methods admitted as sufficiently accurate in other branches of engineering practice.
16. That the weather at the time did not contribute to the accident.

The report includes a comparison of R-38 with R-33 from which design data were taken.

Paint Company Operating Novel Pigment-Making Process

The Pacific Color Manufacturing Co., which was organized a year ago to develop the patents of H. D. Swartout, has brought the first unit of its plant at Chilliwack, 70 miles east of Vancouver, B. C., to the producing stage. The process that the company employs for making pigments consists of dissolving galena in dilute nitric acid contained in duro-iron retorts, of special design, heated by steam. The resulting nitrate of lead is drawn off into vats, where the lead is precipitated in different forms by various reagents, giving the desired pigments, while the oxides of nitrogen and any nitric acid that distills over are recovered. The insoluble residue is drawn off from time to time through valves at the bottom of the retorts. The patents cover reagents, temperatures and retort design.

The galena is obtained in the form of concentrate from the Florence Silver Mining Co., which is operating a silver-lead mine at Ainsworth, in West Kootenay. The contract with the mining company calls for a concentrate containing not less than 60 per cent of lead. The first carload delivered contained 67.8 per cent of lead, 8 per cent of iron, and 3 per cent of zinc. The company is using 5 tons of concentrate daily, but expects during the next few months to install another battery of five retorts, which will double its output. The nitrate solution, after the precipitation of the lead salts, will be evaporated and sold for fertilizing purposes.

Soap-Making and Therapeutics Related in Colloid Chemistry

The Lehigh Valley Section of the American Chemical Society was addressed by Martin H. Fischer of Cincinnati at a regular meeting held Feb. 17 at the Hotel Allen, Allentown, Pa. Dr. Fischer chose as his subject, "The Theoretical and Practical Aspects of the Colloid Chemistry of Soaps," his remarks on the application of colloid chemistry to soap making being illustrated by a large exhibit of samples. The speaker also pointed out the relation between the "salting out" of soaps to the neutralization of mercury and lead poisons in the human body by the use of sodium and potassium salts.

Destruction of Dirigible Emphasizes Need for Helium Plants

That no small part of the responsibility for the Roma disaster may be laid at the door of Congress is an opinion very generally held among technical men in Washington. There is unusual frankness on the subject and much space has been given by the newspapers to statements pointing out that helium should have been available for use in this aircraft. The failure of Congress to provide the small appropriations asked was said to be the only reason that sufficient helium was not available. It is pointed out that a valuable natural resource is being allowed to go to waste, although its complete practicability has been proved by the operation of the C-7, which has made upward of fifty trips without any loss of the helium with which it is filled. Representative Lanham, of Texas, has given notice that he will urge that $800,000 be made available at the earliest possible moment for the government's helium plants.

Military Affairs Committee Considers Merits of Muscle Shoals Offers

The most interesting development of the week in the Muscle Shoals negotiations was the transmission to Congress of the offer of the Alabama Power Co., accompanied as it was with the comments of the Secretary of War which emphasized its favorable features.

A detailed statement of the situation with regard to the Gorgas-Warrior plant was made to the committee by J. H. Burns, who until recently was in charge of the Nitrate Division of Ordnance. He explained that the Alabama Power Co. had in operation at the time of the war a 20,000-kw. plant located on the Warrior River. So as to be assured power for the chemical end of the project before power could be made available at Muscle Shoals, a plan was worked out whereby the Alabama Power Co. was to furnish 30,000 kw. provided the government increased the facilities at Gorgas.

"The Alabama Power Co." he said, "agreed to put up this additional plant at cost plus 6 per cent, and definitely agreed that the company would buy back the plant from the government at a specified time at a fair value, to be determined by a board of arbitrators.

"The arrangement was an expedient to get quick power in order to get explosives at No. 2 plant. It seemed to be the very best solution that could be made of the problem at that time. This arrangement with the Alabama Power Co. was a great help to the government in the early days of the war, as it gave us power at the No. 2 plant in May, 1918, a few months after the plant was started and we were never short of power as a result of that connection. Our own steam plant at Muscle Shoals was not accepted finally until long after the armistice.

"Since the time limit provided in the contract has not been reached, no negotiations for the return of the plant have been undertaken. In case the sale is not consummated to the Alabama Power Co., the government must remove its portion of the plant and leave the land in satisfactory condition."

In explaining the difference between the Alabama Power Co.'s contract and that with the Air Nitrates Corporation, Major Burns said: "The American Cyanamid Co. cannot buy Plant No. 2 unless it is willing to make as good a proposition to the United States as the United States is able to get from any other person. It is my judgment that the American Cyanamid Co. would not give the United States as much as Mr. Ford is offering to give. Therefore I feel that the American Cyanamid Co.'s option will not be an impediment."

Ford Bound to Conduct Research

From the beginning of the hearing it has been evident that the committee attached great importance to lack of definiteness in the Ford offer in the matter of fertilizer manufacture. Even the Secretary of Agriculture qualified his approval of the Ford proposal by specifying that its terms must be found binding so that the plant will be operated continuously for the manufacture of fertilizer. In an effort to meet this objection, Mr. Ford has agreed to alter the contract so as to give a definite guarantee to produce a complete fertilizer at a given minimum annual tonnage. In his testimony before the committee, W. B. Mayo, chief engineer of the Ford Motor Co., made it very clear that it had been Mr. Ford's intention from the first to produce a complete fertilizer. It was his idea, however, that the contract should not make it binding to produce fertilizers at a loss. He agreed that Mr. Ford's company is bound by the proposal to conduct experiments and research work throughout the 100 years. "The only valid reason for discontinuing," said Mr. Mayo, "would be that it had been proved by every possible effort to be an absolute impossibility to make the product there with a profit."

Fertilizer Interests Point Out Existence of Surplus of Ammonium Sulphate

C. H. MacDowell, president of the National Fertilizer Association, in his recent testimony declared that there is no necessity for the manufacture of nitrate for agricultural purposes. He said that coke ovens and city gas works have a capacity of 550,000 tons of sulphate of ammonia annually and that after the fertilizer and other domestic demands are met there still would be an exportable surplus of about 150,000 tons.

The need for maintaining Nitrate Plant No. 2 in readiness for an emergency was emphasized by Mr. MacDowell, who was in charge of the chemical division of the War Industries Board for a time during the war. At that time the country was mainly dependent on Chile for its nitrogen. Stocks fell so low at one time during the war that they were sufficient only for 4 weeks requirements. As a result of that grave experience, he said, there is every reason why the plant should be retained in standby condition ready for operation.

Surplus of Ammonium Sulphate Only Temporary, Says Whitney

Particular significance was attached to the testimony of Milton Whitney, chief of the Bureau of Soils, in view of the fact that some of the arguments made before the committee have been based on the existing price of ammonium sulphate. The inference drawn from Dr. Whitney's remarks by some members of the committee is that decided increases in prices may be expected as the use of fertilizer returns to the normal rate.

"We have an overabundant supply just now of nitrogen in all of its forms," said Dr. Whitney, "because the farmers did not purchase last year. Under normal conditions we have been keeping up with the demand for fertilizers, but there has been an impossibility of getting nitrogenous material in sufficient amount for any great expansion in their use. I have had this matter up with the fertilizer manufacturers. If they were to be successful in getting a demand for 2,000,000 tons of fertilizers in the wheat and corn states, we then could not get the nitrogen to supply it.

"With the demand for fertilizers increasing 7½ per cent per annum, it is becoming more and more difficult to get adequate supplies of ammonia. We have plenty of phosphoric acid and we are searching very diligently for potash; anyway we can get it from the European sources. Nitrogen is the limiting factor. If we have the fixed nitrogen products, we must change our fertilizer system in order to use them to the best advantage."

Fertilizer Investigation Proposed on Charges of Muscle Shoals Lobbying

A resolution to investigate an alleged fertilizer trust which is said to be lobbying against acceptance of the Ford offer to lease the Muscle Shoals plant was introduced in the Senate by Senator McKellar of Tennessee on Feb. 17. The proposed investigation would be conducted by the Senate Agriculture Committee to determine whether there is a fertilizer trust, whether the industry is controlled by a combination of corporations and whether it has employed lobbyists to influence Congress against accepting the Ford offer.

Industrial Developments of the Week

Glass. — The American Window Glass Co. has resumed operations at its plant at James City, near Kane, Pa., following a shut-down since early in December.

The B-R-C Bottle Co., Cedar Grove, La., has resumed operations at its plant after a period of curtailment. Employment will be given to about 200 men.

The Owens Bottle Co., South Glassboro, N. J., is operating its bottle-blowing plant at full capacity, with three-shift working forces.

Paper. — The American Writing Paper Co., Holyoke, Mass., has resumed production at its local Gill division plant, following a period of curtailment. Operations will be on a basis of 60 tons of paper per day.

The J. C. Blair Co., Huntingdon, Pa., manufacturer of paper specialties, has advanced production to a full-time schedule of 54 hours a week. The plant has been running on a short-time basis since last year.

Leather.—The E. C. Mills Leather Co., Middleville, N. Y., is operating at a capacity schedule at its tannery.

Tarlow Bros., Brockton, Mass., are maintaining operations on a full capacity schedule.

McAdoo & Allen, Philadelphia, Pa., are increasing production at their welting plant at Quakertown, Pa. and are arranging for early expansion, providing additional floor space and increased working force.

Refractory.—The National Fire Brick Co., New Philadelphia, Ohio, has resumed production at its local plant, following several weeks idleness.

Iron and Steel.—The Pittsburgh Steel Co., Pittsburgh, Pa., has resumed operations at six furnaces at its open-hearth plant.

The Berwick Rolling Mills, Berwick, Pa., have reopened the finishing department at their local plant, following a period of curtailment, and will give employment to about 200 additional men.

The Hanna Furnace Co., Cleveland, Ohio, is making repairs at its furnace at Dover, Ohio, and placing the unit in readiness for blowing in. It has been closed down since December, 1920.

The Carnegie Steel Co., Pittsburgh, Pa., is operating two of its Lucy furnaces full, for the production of ferromanganese and spiegeleisen.

The Follansbee Bros. Co., Pittsburgh, Pa., is operating on a full time schedule at its steel mills at Follansbee, W. Va., recently reopened.

The Illinois Steel Co., Chicago, Ill., has placed another furnace in blast at its Gary, Ind., works, making a total of eleven stacks now active, comprising six at Gary, four at the South Chicago works and one at Joliet, Ill.

The Jones & Laughlin Steel Co., Pittsburgh, Pa., has seven blast furnaces operating full for the production of iron. It is planned to place another furnace in blast at the Woodlawn works for the production of ferromanganese at an early date.

The Inland Steel Co., Chicago, Ill., has adopted a capacity schedule in its sheet department. The structural mill, continuous mill and nine open-hearth furnaces are also active. It is proposed to resume operations at the plate mill at an early date.

Metals.—The El Paso Smelting Works, El Paso, Tex., is making ready to resume operations at five of its lead furnaces, which will be more than have been in service for a number of years past. The company is also planning for early resumption of operations in the copper furnace department.

The Nevada Consolidated Copper Co., Ely, Nev., has arranged for the immediate resumption of production at its local smelters on a 60 per cent basis. The mines, also, will be reopened.

The Anaconda Copper Co. is increasing production at its Great Falls, Mont., electrolytic plant from 2,000,000 to 4,000,000 lb. of copper per month. This will be increased to a maximum of 7,000,000 lb. as soon as sufficient concentrates from the mines are available.

Powder.—E. I. du Pont de Nemours & Co. are giving employment to about 500 operatives at their Carneys Point, N. J., plant, under full-time operation.

Connecticut Valley Section, A.C.S.

The Department of Chemistry of Smith College was host to the Connecticut Valley Section of the American Chemical Society on Feb. 4, 1922. The members were given opportunity to inspect the college laboratories and to visit the mills of the McCallum Hosiery Co., the Nonotuck Silk Co. and the Florence Manufacturing Co.

The speaker of the day was W. T. Bovie of Harvard University, who addressed the section on "The Structure of Protoplasm."

Personal

HARRY BREARLEY, works manager of Brown Bayley's Steel Works, Sheffield, England, and well known for his writings on steel metallurgy, is in the United States for a brief stay.

J. A. CULLEN has been assigned to cement experiment work at the Columbus Station of the U. S. Bureau of Mines.

H. A. DOERNER has been assigned to rare-metal work at the Reno experiment station of the Bureau of Mines. Mr. Doerner was formerly connected with the Denver office of the Bureau of Mines. For several years past he has been engaged in commercial work.

F. B. FOLEY, metallurgist, Minneapolis Station of the Bureau of Mines, has been in Washington recently. He presented a discussion of "The Annealing and Hardening of Steel" before the Washington Chapter of the American Society for Steel Treating at its monthly meeting Feb. 17.

J. J. FORBES, coal-mining engineer of the Bureau of Mines, is collecting data for the preparation of a bulletin on sampling and analysis of Alabama coals. This bulletin will give information regarding the coals of the Birmingham district. One hundred and forty-nine face samples of coal have been taken in thirty-four mines in Alabama, representing fourteen different coal beds.

A. P. GEST, JR., formerly assistant superintendent of the Frankford Plant of The Barrett Co. and more recently in the technical service department as expert on the industrial uses of coal-tar solvents, is now associated with Keator & Wilson, Philadelphia, Pa., as Eastern representative of the St. Louis Pump & Equipment Co., St. Louis, Mo., and of Morrison Bros., Dubuque, Iowa.

C. F. GRASS, president and general manager of the American Nitrogen Products Co., Seattle, Wash. was in New York last week.

H. W. HARDINGE, of Hardinge Co., New York, sailed Feb. 15 on the S. S. *Baltic* for Europe, and plans to return about the middle of April.

HAROLD E. MARTIN, who last May left the General Chemical Co., where he was employed as an engineer in the research department, is now with Johns-Manville, Inc., in the New York insulation and power plant specialties department.

Dr. DUNCAN MACRAE, physical chemist for the Westinghouse Lamp Co., delivered a lecture on "Physical Chemistry and Some of Its Applications" before the senior class in chemistry of the Cooper Union night school on Feb. 23.

Dr. C. E. KENNETH MEES, director of research and development, Eastman Kodak Co., gave several lectures in Montreal and Toronto during the last week of February. On Feb. 20 at Montreal he spoke before the Canadian Club on "The Road to Wealth." The same evening he lectured before the Montreal Section of the Society of Chemical Industry on "Chemistry and the Motion Picture." At Toronto he gave the following lectures: Feb. 21, "Photography Through the Microscope," before the Camera Club; Feb. 22, "Chemistry and the Motion Picture," before the Toronto Section of the Society of Chemical Industry; Feb. 23, "The Getting of Wisdom" before the Empire Club, and "A Hundred Years Hence," before the Canada First League.

Dr. CLARK MINTER, of the Hanovia Chemical Co., delivered a lecture on "Osmotic Pressure" before the senior class in chemistry of the Cooper Union night school on Feb. 9.

Market Conditions

IN CHEMICAL, METALLURGICAL AND ALLIED INDUSTRIES

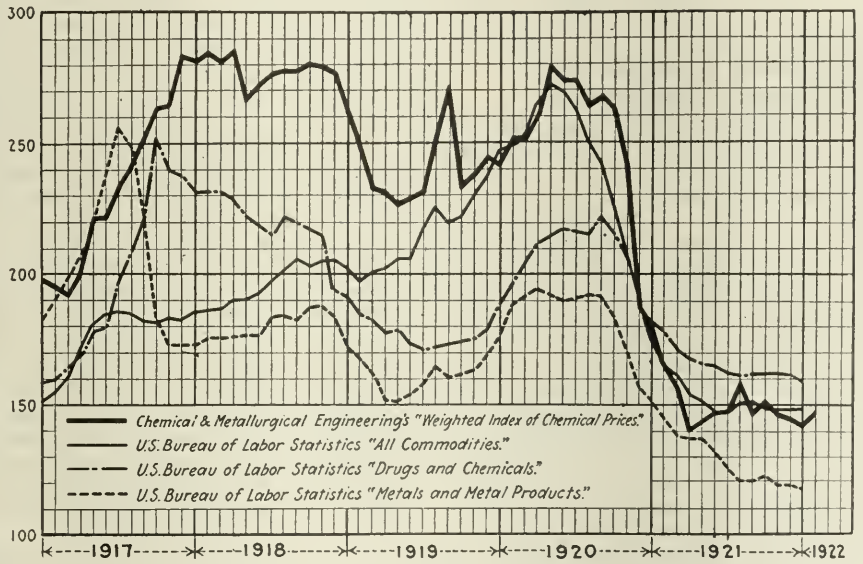
A Survey of the Economic and Commercial Factors That Influence Trade in Chemicals and Related Commodities—Prevailing Prices and Market Letters From Principal Industrial Centers

Fundamental Progress in Business During February

Underlying conditions improved somewhat during February, but the progress toward better business has been slow and painful. The general upward trend of business has been punctuated with reactions, many of which had depressing effects on industry.

Outstanding among the developments of the month have been the threatened coal strike with its almost inevitable consequences to industry, the serious agitation for the soldier bonus with its menace to business progress, and the continued wage disputes, which have added greatly to the ranks of the unemployed. On the other side of February's ledger are to be noted the striking rise in foreign exchange, the noticeable upturn in certain commodity prices, and finally the announcement of the government's more sympathetic attitude toward industry as evidenced by Secretary Hoover's defense of the trade association and other methods of modern business.

The proposed miners' strike, directly involving soft- and hard-coal miners in more than twenty states, may have a most serious effect on industry if we are to judge from the disastrous results of the late British coal strike. Even today Great Britain's foreign trade is suffering from ailments which economists declare are directly attributable to that long tie-up of industry. As is doubtlessly well known, all wage agreements in American coal mines will terminate April 1 and unless the miners force the acceptance of a new and higher wage scale, production will cease. The effects will be felt most seriously by industry, for supplies are adequate to meet the householders' demands, especially since in most sections, the weather will have moderated considerably by April 1. Those most familiar with the situation are confident that, whatever the temporary consequence, the net result will be a downward turn in the present inflated prices of coal. Still 90 per cent above pre-war levels, lower coal prices are generally regarded as inevitable.



A COMPARISON OF WHOLESALE PRICES, 1917-1922

The sensational financial development of the past month has been the sharp rise in sterling and the sympathetic strengthening of practically all of the other exchanges. After averaging $4.16 for December and $4.22 for January, the British pound opened the past month at $4.28, crossed $4.37 on Feb. 9, and then after a temporary slump, jumped to 4.41\frac{5}{16}$ on Feb. 23. This is the highest level reached since 1919. The exchange on Paris has risen from $0.0835 on Feb. 1 to $0.0913 on Feb. 24 and the Italian lire from $0.0466 to $0.0502. The business situation in Great Britain is not generally regarded as sufficient in itself to have so strengthened the exchange. The most likely explanation is that it is the cumulative effect of smaller imports, the apparent arrangements to provide £25,000,000 to cover 6 months interest on the English debt to the United States, and finally the larger exports of gold. Announcement was made on Feb. 20, that in the one week ended Jan. 18 Great Britain had exported £1,276,816 in gold to the U. S.

On Feb. 3 wages in the textile mills of the three states of Massachusetts, New Hampshire and Maine were greatly reduced. Other states immediately followed suit. This cut of 20 per cent, following a general reduction of 22½ per cent which was put into effect early in January, 1921, has resulted in a strike of very generous proportions. The chemical industry is not so organized as to be affected by such blanket wage decreases, but during the past month more than one prominent dyestuff and chemical manufacturer has made drastic reductions both in salaries and personnel. Reducing wages is the most obvious path to lower costs, but it is also the most difficult.

CHEMICAL & METALLURGICAL ENGINEERING'S WEIGHTED INDEX OF CHEMICAL PRICES

Base = 100 for the year July 1, 1913, to June 30, 1914

This week	151.21
Last week	149.05
March, 1921	157
March, 1920	252
April, 1918 (high)	286
April, 1921 (low)	140

This index number is based on the wholesale prices in the New York market for acetic acid, citric acid, hydrochloric acid, nitric acid, sulphuric acid, ethyl alcohol, methanol, anhydrous ammonia, ammonium sulphate, barium chloride, bleaching powder, borax, caustic potash, caustic soda, copper sulphate, formaldehyde, glycerine, potassium carbonate, saltcake, soda ash, crude sulphur, benzene, aniline oil, cottonseed oil and linseed oil.

Wholesale Prices

Although the general level of prices has probably remained almost stationary, a number of important commodities have shown an upward tendency during February. Particularly is this true in the chemical market. CHEMICAL & METALLURGICAL ENGINEERING'S Weighted Index of Chemical Prices stood at 144.60 on Feb. 1, increased to 147.33 on Feb. 8, to 149.05 on Feb. 22 and on March 1 had risen to 151.21. This is highest level of chemical prices

since October, 1921. These higher prices are not necessarily to be regarded, however, as progress toward business recovery in the chemical industry. They may mean speculation and artificial activity, but as has often been pointed out in these columns, the essential requirement is the proper adjustment between the great groups of commodity prices and between such economic factors as costs, wages and transportation.

Wholesale Prices in January

The U. S. Bureau of Labor Statistics index numbers indicate that wholesale prices in general averaged somewhat lower in December than in the preceding month. The bureau's "all commodities" index number, comprising 327 price series, stood at 148 for January, compared with 177 for January, 1921.

Below are shown the index numbers of wholesale prices in the United States, by groups of commodities, as computed by the Bureau of Labor Statistics for the months named.

INDEX NUMBERS OF WHOLESALE PRICES, BY GROUPS OF COMMODITIES. (1913 = 100)

	1921		1922
	January	December	January
Farm products	136	113	116
Food	162	139	134
Cloths and clothing	208	185	183
Fuel and lighting	228	187	183
Metals and metal products	152	119	117
Building materials	239	203	202
Chemicals and drugs	182	161	159
Housefurnishing goods	283	218	214
Miscellaneous	190	148	146
All commodities	177	149	148

Working Hours and Wages in the German Chemical Industry

A report on the labor supply of the German chemical industry, comparing the working hours in 1913 and 1921, has recently been made by Dr. C. Duisberg. Labor conditions have apparently varied considerably in the individual factories of the Rhineland district. Before the war, the working day at the Bayer Farbwerke was 9 hours (from 7.30 a.m. to 6 p.m. with a midday break from 12 to 1.30), but as a rule most factories worked 10 hours. Heavy manual laborers, such as stokers and workers in the heavy chemical industries, worked an 8-hour day.

This report, which has been summarized in a late issue of the *Journal of the Society of Chemical Industry*, states that at Hoechst, in 1913, the 10-hour day was the rule. At the works of the Aktiengesellschaft für Anilinfabrikation, Berlin, the length of the working day varied with the nature of the work performed. The 12-hour day was worked at Berlin-Treptow, the 10-hour day in the Filmfabrik Wolfen (6 a.m. to 6 p.m. with 2-hour rest) and either 11 or 13 hours in the Rummelsburg works. A special working day of 8½ hours for women was provided in one of the plants.

At the Badische Anilin- und Soda-Fabrik at Ludwigshaven, labor conditions were said to resemble those at the Leverkusen plant of the Bayer company. The 9-hour day (7.30 a.m. to 12 m. and 1.30 p.m. to 6 p.m.) was the usual basis, although the pay was for 10 hours. In some instances where there was need for continuous service the men worked in 12-hour shifts from 6 to 6 and were paid for 13 hours.

Directly after the revolution in November, 1918, the 8-hour day was introduced into the chemical industry. Among the rules set down by the German *Reichsanzeiger* were the following:

"The working time, including rest periods, shall be 8 hours.

"By agreement, the working hours on Saturday may be shortened, the time lost being spread over other days.

"Female workers over 16 years may be employed, where two or more shifts are worked, up till 10 p.m., provided they are then allowed a rest period of at least 16 hours."

These rules are said to have been universally accepted in the chemical industries. The 8-hour day, with a half hour break from 12 to 12.30 p.m. is most common. Where shifts are worked they commence at 5.55 a.m., 1.55 p.m. and 9.55 p.m. and end at 2.05 p.m , 10.05 p. m. and 6.05 a.m. respectively.

The New York Market During February

NEW YORK, Feb. 27, 1922.

The chemical market during the past month showed very little signs of recovery. On the surface, the total amount of business for February seems to have increased over the preceding month. However, the persistent conservatism on the part of buyers to limit their purchases to immediate requirements, together with the policy of large manufacturers to hold production at a minimum, has had a disastrous effect on the general trend of trading and has retarded any forward movement. The steady arrivals of imported materials at extremely low figures has also been a severe handicap and has caused serious consideration among many of the largest domestic producers.

During a recent address before the Rochester Section of the American Chemical Society, Dr. W. J. Hale of the Dow Chemical Co. stated that his company is selling at 12c. per lb. bromide which is actually costing 23½c. per lb. to produce and is doing this in order to prevent the Germans from dumping on the American market vast quantities of the product now held in Eastern warehouses.

One of the encouraging developments of the month was the advance in foreign exchange, and this has been reflected in the export market in the form of expansion in trading and has also served as a limited bar on imported materials. Foreign buying during the past few weeks has been practically the only hopeful sign in the industry and an appreciable increase has been reported in many quarters. Frequent sales of large tonnages were noted to Japan, Mexico, Italy and South America.

The prussiate market continued its steady advance, with the demand heavy and supplies exceedingly scarce. Yellow prussiate of soda reached a new high level when sales were recorded at 18½c. per lb. Red prussiate of potash became a nominal proposition during the month as prices soared from 33c. to 60c. per lb. Spot supplies have been wiped out of the market and futures have been reported in only a very limited way. Another item that has been of some market interest is linseed oil. Opening the month at 74c. per gal. for the raw product in carload quantities, prices advanced to a high level of 86c. per gal. for February shipments. Leading interests predict a much higher market with the season closely ahead. The alkali market has shown a decided decline since the opening of February owing to increased competition and large spot supplies of imported material. Caustic soda opened the month at $3.60 per 100 lb. and reached a low mark of $3.25 toward the close. Soda ash sold during the early part of the month at $1.80 per 100 lb. and factors at the close were selling carload lots at $1.65. Imported ash has been a serious factor to the domestic producers.

DEVELOPMENTS OF THE WEEK

Trading, in general, has uncovered no striking developments during the past week. Small lots still continue to rule the market, although a few inquiries were noted for round quantities at a fraction under quoted figures. There were rumors in the trade that imported nitrite of soda was slated for a sharp advance and holders began to tighten offerings with the memory of the March, 1920, movement that resulted in increasing the price to 60c. per lb. Domestic producers have already advanced prices a full cent per lb., making the market 8½c. per lb. at the works. Oxalic acid was reduced by leading interests to 12c. per lb. This is the lowest first-hand price since last November. Competition was responsible for a reduction in formaldehyde at the works. Caustic soda has merited added attention for export and considerable small-lot business has been placed at slightly higher figures. Prussiate of soda touched a new high mark of 8½c. per lb. This is the highest price paid since November, 1920.

THE COMMODITY MARKETS

Alums—Ammonia alum held by domestic producers was quoted on a basis of 3½@3¾c. per lb. for the lump. Imported potash alum is quoted freely at 3¼@3½c. per lb.

Barium Chloride—Sales were recorded during the week at slightly lower figures—around $55 per ton on spot.

The market was very firm at the figure toward the end of the week, with some interests asking up to $57 per ton.

Bicarbonate of Soda—Producers' quotations remain unaltered at 2c. per lb. for barrels f.o.b. works. Spot material, however, is on the market as low as $2.10 per 100 lb. Some small lot sales were made at $2.15.

Caustic Potash—There was an appreciable improvement noted in the consuming inquiry for the imported. The 88-92 per cent is quoted at $5.65@$5.75 per 100 lb., with shipment goods held at $5.60@$5.85 c.i.f. Domestic producers are still asking 8c. per lb, f.o.b. works.

Caustic Soda—Leading factors stated that February shipments have been heavily sold and the market looks much firmer. March shipments are quoted at $3.35@$3.40 per 100 lb. f.a.s. and April at $3.30, although the latter can possibly be purchased on a firm bid of $3.25. Export inquiries are holding up fairly well.

Citric Acid—The consuming inquiry has not shown any appreciable increase, but the tone of the market is much stronger, owing to the advice from abroad indicating a restricted output. Some of the largest producers in Italy were reported to be closed down. Spot goods are quoted at 45c. per lb.

Formaldehyde—The domestic as well as the export demand continues quiet and the market has shown the effect of the competition for new business. Producers quote from 9@10c. per lb., f.o.b. works, in barrels.

Nitrite of Soda — A distinctly firmer market has been brought about with the exhaustion of spot foreign supplies and some domestic factors have advanced their prices to 8½c. per lb. at works. There are only a few scattered lots available on the open market at this figure.

Oxalic Acid—Leading producers reduced prices sharply at the works. Goods were offered at 12c. per lb. and upward, depending on the quantity and seller.

Prussiate of Soda—Very firm conditions continue to prevail for spot material. Limited offerings and a good consuming inquiry have been sufficient to create this condition. Dealers report sales at 18½c. per lb. and it is doubtful if better prices could be obtained in any direction.

Shellac—The market has been very active during the past week and prices moved upward from 5@7c. per lb. on practically all grades. Arrivals at New York were reported larger, but as a market factor this was completely overshadowed by the receipt of news that a large cargo of shellac from Calcutta has been wholly or partly destroyed by fire. The demand was active for nearby material. T. N. was quoted at 73c. per lb., superfine at 77c.

The Chicago Market

CHICAGO, ILL., Feb. 23, 1922.

A slight improvement of the general conditions in the industrial chemical market was noted during the past week. Sales have increased and the inquiry is more active. Buying continues to be for small or moderate quantities but the volume of this business is reported as very satisfactory. Prices as a rule are unchanged and the tendency with a few exceptions is upward. This upward trend is to be noticed particularly on chemicals of foreign origin as cable quotations from abroad were sharply higher.

GENERAL CHEMICALS

Contract business for alkalis is reported as brisk and small sales from warehouse stocks as dull. Prices are slightly weaker in some directions, which is probably due to the necessity of moving present stocks. Small lots of solid *caustic soda*, 76 per cent, were quoted at $3.75 per 100 lb. delivered to the consumer. *Soda ash* on spot was rather quiet with $2.30 per 100 lb. for 58 per cent material in cooperage the prevailing offer. *Caustic potash* was firm at 6½c. per lb. for 88-92 per cent material.

Ammonium chloride is unchanged as to price and is reported to be moving fairly well at 7¾c. per lb. for the white granular in casks. *Ammonium carbonate* is rather quiet and small lots on spot are offered at 9@10c. per lb. *Bleaching powder* is firm at 3c. per lb. delivered and is said to be moving in a fair way. *Copper sulphate*, like the metal, is very firm and 6c. was the prevailing quotation, although it was still possible to do $5.90 per 100 lb. in one direction. While *formaldehyde* was reported to be moving well, prices were a little weak and 10c. per lb. could very likely have been shaded for a fair-sized lot. *Glycerine* was in fair demand and unchanged at 16½c. per lb. for c.p. material in drums. *Epsom salts* are in but small demand with plentiful supplies of U.S.P. material available at 2¾c. per lb.

Bichromates are enjoying a fair demand and supplies are reported to be not very heavy. *Potash bichromate* is quoted in single-cask lots at 11¾c. per lb. and the soda at 9@9½c. *Yellow prussiate of potash* is in brisk demand and with supplies light, prices are firm at 27@28c. per lb. The market is entirely clear of the *red prussiate* and even a firm offer for future delivery could not be had. Cables abroad also failed to locate any material for prompt shipment. Several large sales of *sodium bicarbonate* were reported, but aside from these only a few small lots changed hands. Spot material in cooperage is available at $2.35 per 100 lb. *Hypo* is very quiet, with only small parcels moving. Prices remain the same, $3.95 per 100 lb. for pea crystals in barrels. *Silicate of soda* appears to be moving in a fair way and single drums of the 40 deg. material is quoted at $1.40 per 100 lb., drum extra.

Linseed Oil — The movement of linseed oil continues slow, buyers showing a pronounced reluctance to take on even small supplies at the present high level. Boiled oil in single drum lots was offered today at 88c. per gal., drum extra, and similar lots of the raw at 86c.

Naval Stores—Turpentine is slightly lower in price but the movement continues slow. Single drums were quoted today at 95c. per gal., drum extra, delivered to the buyer's store. Rosin is moving in a fair way and $8.50 per 280 lb. was today's prices of the WW grade in less than carlots.

Furfural—Technical furfural was available for the first time in commercial quantities, the offer being 50c. per lb., drums extra, for quantities larger than 100 lb.

The Iron and Steel Market

PITTSBURGH, Feb. 24, 1922.

Steel mill operations have increased a trifle more in the past week, reflecting still heavier buying, since practically all production is against orders placed for prompt shipment. The rate of steel ingot production in the past fortnight has probably averaged 27,000,000 or 28,000,000 tons per annum, against a rate under 18,000,000 tons at the end of December and a rate of 23,000,000 tons in October and November, denoting the volume of last autumn's demand. Thus with spring not yet arrived the demand rises well above that of last autumn. When eventually the curve of production can be plotted, this spring's demand is likely to represent 25 or 30 per cent more demand than that of last autumn, while a reasonable expectation is that next autumn will show a higher tide still.

Up to date there is no indication that buyers will depart from their practice of buying steel practically from hand to mouth. The old practice of distributers and manufacturing consumers carrying large stocks of steel, and of various interests carrying large stocks of manufactured wares, seems to be abandoned for quite a period. A necessary consequence would be that of demand upon the steel mills exhibiting much greater seasonal variations than has ever been the case before. Part of the ups and downs in steel demand has been due to buyers accumulating stocks at one time and liquidating at another time, these movements having no particular connection with the calendar.

There is lacking any comprehensive method of determining what the consumptive requirements or capacity of the country really are. When it is known, for instance, that steel ingots are being produced at the rate of, say, 28,000,000 tons per annum, there is no standard with which to compare this number of tons except the productive capacity, and that obviously is not a standard equally applicable to consumption. The happy state of productive capability and consumptive capability being balanced is unlikely to obtain in any commodity. That is one reason why the practice much in vogue in the past of indicating the rate of steel production by expressing it in terms of percentage of productive capacity is avoided in these reports. Such statements are both misleading and depressing. The

capacity has been estimated for some time past at about half way between 50,000,000 and 55,000,000 tons, in steel ingots.

A Broad Demand

The breadth of steel demand is the most conspicuous feature of the market. The agricultural implement trade is conspicuous for its almost complete absence, while practically every other steel-consuming industry is buying in a fair way. The electrical industry is buying much more freely than 2 or 3 weeks ago. Material required in dwelling house construction is doing very well, illustrated by there being a demand not far from normal for standard steel pipe, while the sheet mills are receiving larger orders from makers of eave trough and conductor pipe, metal lathing and ceiling, etc. Although out of season, the petroleum industry is buying in a very moderate way. The automobile trade is taking fair tonnages and is buying steadily instead of for extended deliveries. Railroad buying is somewhat more in evidence.

All appearance that buyers of steel are waiting for something to turn up is a thing of the past. Business is being conducted, and buyers are ordering freely. They do not buy for extended delivery and perhaps will not do so for a long time to come. A distinct possibility, however, is that of mills falling somewhat behind in deliveries whereby buyers would be forced to stock up in a moderate way instead of depending on mills for almost instant shipment against mixed specifications. This would create an extra tonnage demand for a time, the more important feature from the mill standpoint being that it would permit of better and more economical scheduling of rollings.

Steel Prices

With the gradual sagging in prices of bars, shapes and plates already reported, whereby 1.40c. became the more common market price, there is a tendency for this price to be adhered to with considerable strictness. It is possible that the market may be what is called "stabilized" at this figure, with the possibility of some contracting at this price, to be followed by a slight advance to "protect the contracts" in accordance with a principle the mills frequently invoked before the war. Certainly there is no room, with wages and freight rates as they stand, for the general market to go an appreciable amount lower.

In sheets the prices ruling for about 3 months past, 2.25c. on blue annealed, 3c. on black and 4c. on galvanized, are well maintained. Separate testimony to that fact is afforded in the American Sheet & Tin Plate Co. opening its order books, Feb. 20, for second quarter business at these figures. On the heavy gages, say 12 gage and under, there is plate mill competition.

Wire nails, which have been $2.40@$2.50 for several weeks, depending on size of order, show the $2.40 price more and more frequently. In standard steel pipe the extra concession of 2½ per cent, commonly given by independents, has lately been more often 5 per cent, and at present a total of 7½ per cent is sometimes found.

Pig Iron

Basic pig iron presents rather a complicated market. The furnaces insist that they are firm at $18 valley as minimum, with an asking price of $18.25, but a recent purchase reported to have been at $18 valley is believed in some quarters to have been of resale iron, from a middle interest, at $17.65. Foundry iron has been bought from a valley furnace in one case at $18.75, though some sales have also occurred at the old minimum of $19. Bessemer is down 50c., being quotable at $20.96 delivered Pittsburgh or $19 valley, the occasion being a sale of a few hundred tons by the Cambria Steel Co., which recently decided to devote part of its furnace capacity to the production of merchant iron. Freight to Pittsburgh is the same from Johnstown as from the valleys, $1.96.

Connellsville coke maintains the advance reported a week ago, but has not advanced farther, spot and prompt being quotable at $3.25@$3.50 for furnace and at $4@$4.25 for foundry per net ton at ovens.

General Chemicals

CURRENT WHOLESALE PRICES IN NEW YORK MARKET

		Carlots	Less Carlots
Acetic anhydride	lb.	..... -	$0.40 - $0.42
Acetone	lb.	$0.12½ - $0.12½	.13 - .13½

Coal-Tar Products

NOTE—The following prices are for original packages in large quantities:

Alpha-naphthol, crude	lb.	$1.00 — $1.05
Alpha-naphthol, refined	lb.	1.10 — 1.15
Alpha-naphthylamine	lb.	.28 — .30
Aniline oil, drums extra	lb.	.16½ — .17
Aniline salts	lb.	.24 — .26
Anthracene, 80% n drums (100 lb.)	lb.	.75 — 1.00
Benzaldehyde U.S.P.	lb.	1.30 — 1.35
Benzidine, base	lb.	.85 — .95
Benzidine sulphate	lb	.75 — .85
Benzoic acid, U.S.P.	lb.	.60 — .65
Benzoate of soda, U.S.P.	lb.	.55 — .57
Benzene, pure, water-white, in drums (100 gal.)	gal.	.29 — .35
Benzene, 90%, in drums (100 gal.)	gal.	.27 — .32
Benzyl chloride, 95-97%, refined	lb.	.25 — .27
Benzyl chloride, tech	lb.	.20 — .23
Beta-naphthol benzoate	lb.	3.75 — 4.00
Beta-naphthol, sublimed	lb.	.60 — .65
Beta-naphthol, tech	lb.	.28 — .30
Beta-naphthyla mine, sublimed	lb.	1.50 — 1.60
Cresol, U. S. P., in drums (100 lb.)	lb.	.15 — .16
Ortho-cresol, in drums (100 lb.)	lb.	.18 — .20
Cresylic acid, 97-99%, straw color, in drums	gal.	.50 — .52
Cresylic acid, 95-97%, dark, in drums	gal.	.45 — .47
Dichlorbenzene	lb.	.06 — .09
Diethylaniline	lb.	1.05 — 1.10
Dimethylaniline	lb.	.39 — .41
Dinitrobenzene	lb.	.21 — .25
Dinitroclorbenzene	lb.	.25 — .27
Dinitronaphthalene	lb.	.32 — .35
Dinitrophenol	lb.	.35 — .38
Dinitrotoluene	lb.	.23 — .25
Dip oil, 25%, car lots, in drums	gal.	.24 — .26
Diphenylamine	lb.	.60 — .70
H-acid	lb.	.90 — 1.00
Meta-phenylenediamine	lb.	1.00 — 1.05
Monochlorbenzene	lb.	.10 — .12
Monoethylaniline	lb.	1.15 — 1.20
Naphthalene crushed, in bbls.	lb.	.06½ — .07
Naphthalene, flake	lb.	.06¾ — .07½
Naphthalene, balls	lb.	.07½ — .08½
Naphthionic acid, crude	lb.	.65 — .70
Nitrobenzene	lb.	.10 — .12
Nitro-naphthalene	lb.	.30 — .35
Nitro-toluene	lb.	.15 — .17½
Ortho-amidophenol	lb.	2.75 — 2.80
Ortho-dichlor-benzene	lb.	.15 — .20
Ortho-nitro-phenol	lb.	.75 — .80
Ortho-nitro-toluene	lb.	.15 — .20
Ortho-toluidine	lb.	.20 — .25
Para-amidophenol, base	lb.	1.25 — 1.30
Para-amidophenol, HCl	lb.	1.30 — 1.35
Para-dichlorbenzene	lb.	.17 — .18
Paranitroaniline	lb.	.77 — .80
Para-nitrotoluene	lb.	.70 — .75
Para-phenylenediamine	lb.	1.50 — 1.55
Para-toluidine	lb.	1.10 — 1.15
Phthalic anhydride	lb.	.35 — .38
Phenol, U. S. P., drums	lb.	.11½ — 15
Pyridine	gal.	1.75 — 2 75
Resorcinol, technical	lb.	1.25 — 1.30
Resorcinol, pure	lb.	1.85 — 2 00
Salicylic acid, tech., in bbls.	lb.	.18 — .20
Salicylic acid, U. S. P.	lb.	.22 — .23
Salol	lb.	.80 — .82
Solvent naphtha, water-white, in drums, 100 gal.	gal.	.25 — .28
Solvent naphtha, crude, heavy, in drums, 100 gal.	gal.	.12 — .14
Sulphanilic acid, crude	lb.	.25 — .27
Tolidine	lb.	1 20 — 1.30
Toluidine, mixed	lb.	.32 — .38
Toluene, in tank cars	gal.	.25 — 28
Toluene, in drums	gal.	.30 — 35
Xylidines, drums, 100 gal.	lb.	.40 — 45
Xylene, pure, in drums	gal.	.40 — .45
Xylene, pure, in tank cars	gal.	.45 — ....
Xylene, commercial, in drums, 100 gal.	gal.	.33 — .35
Xylene, commercial, in tank cars	gal.	.30 — ....

Waxes

Prices based on original packages in large quantities.

Bayberry Wax	lb.	$0 20 — $0.21
Beeswax, refined, dark	lb.	.25 — .26
Beeswax, refined, light	lb.	.30 — .32
Beeswax, white pure	lb.	.35 — .38
Candellila wax	lb.	.24 — .25
Carnauba, No. 1	lb.	.45 — .46
Carnauba, No. 2, North Country	lb.	.24 — .24½
Carnauba, No. 3, North Country	lb.	.14½ — .15
Japan	lb.	.19 — .20
Montan, crude	lb.	.05 — .05½
Paraffine waxes, crude match wax (white) 105-110 m.p.	lb.	.04¼ — 04½
Paraffine waxes, crude, scale 124-126 m.p.	lb.	.02½ —
Paraffine waxes, refined, 118-120 m.p.	lb.	.03½ — .03¾
Paraffine waxes, refined, 125 m.p.	lb.	.03½ — .03¾
Paraffine waxes, refined, 128-130 m.p.	lb.	.04 — .04¼
Paraffine waxes, refined, 133-135 m.p.	lb.	.04½ — .05
Paraffine waxes, refined, 135-137 m.p.	lb.	.05½ — .05½
Stearic acid, single pressed	lb.	.08¾ — .09
Stearic acid, double pressed	lb.	.09¼ — .09½
Stearic acid, triple pressed	lb.	.10¼ — .10½

Naval Stores

All prices are f.o.b. New York unless otherwise stated, and are based on carload lots. The oils in 50-gal. bbls., gross weight, 500 lb.

Rosin B-D, bbl.	280 lb.	$5.30 —	5.35
Rosin E-I	280 lb.	5.40 —	5.45
Rosin K-N	280 lb.	6.05 —	6.80
Rosin W. G.-W. W.	280 lb.	7.00 —	7.25
Wood rosin, bbl.	280 lb.	6.25 —	....

Industrial

Financial, Construction and Manufacturers' News

Construction and Operation

Arkansas

ASHDOWN—The White Cliff Products Co., recently organized to operate in the White Cliffs section, will commence immediately the construction of a crushing and pulverizing plant for the manufacture of whiting, fertilizer and kindred products. It will have a capacity of about 15 tons an hour, and is estimated to cost close to $100,000. Work is under way on a power plant at the property. The company is headed by A. B. Banks, Little Rock, Ark. The Ashdown Chamber of Commerce is interested in the project.

California

NEWPORT BEACH—The Council has called a special election for April 10, to vote bonds for extensions to the municipal artificial gas plant, for reserve supply, to cost about $75,000. Paul E. Kressly, H. W. Hellman Bldg., Los Angeles, is city engineer.

Georgia

PERRY—The Council will install a new filtration plant in connection with an improved waterworks system, plans for which have been prepared by O. H. Sheffield, 505 Peachtree St., Atlanta, Ga., engineer. S. P. Crowell is city clerk.

MACON—The Buckeye Cotton Oil Co., is planning for the erection of a new oil mill on local site. Plans will be prepared at an early date.

SAVANNAH—The Savannah Gas Co. is planning for extensions and improvements in its plant on East Broad St., to cost about $50,000. John W. Golden is vice-president and general manager.

Illinois

EAST ST. LOUIS—The Obear-Nestor Glass Co., 25 North 2nd St., St. Louis, Mo., has excavations under way for the erection of its proposed 1-story plant addition at Broadway and Belt St., to cost about $75,000. It will be equipped for the manufacture of glass bottles.

CHICAGO—The Dryden Rubber Co., 1014 South Kildare Ave., has filed plans for the erection of a 1-story extension, 20 x 77 ft.

Maryland

BALTIMORE—The Holtite Mfg. Co., Warner and Ostend Sts., manufacturer of rubber products, is planning for the erection of a 1-story addition to double the present capacity. Morris Eisen is president and general manager.

Massachusetts

PEABODY—The Hunt Rankin Co., manufacturer of suede leathers, etc., is completing the erection of a 4-story addition, and will place the factory in operation at an early date.

SOUTHBORO—The Dennison Mfg. Co., Framingham, Mass., manufacturer of paper specialties, is having plans prepared for the erection of a 4-story plant, 70 x 300 ft., at Southboro. Monks & Johnson, 99 Chauncey St., Boston, are architects.

WORCESTER—The United States Peat Products Co., recently organized with a capital of $99,000, is considering tentative plans for the establishment of a color pigment manufacturing plant in connection with the development of peat properties. Edmund P. Cummins, Worcester, is treasurer.

BOSTON—The B. O. & G. C. Wilson Co., 196 Cambridge St. manufacturer of chemicals, drugs, etc., is taking bids for the erection of a 5-story plant, 60 x 200 ft., on Farwell St., Waltham, Mass. The H. M. Hope Engineering Co., 185 Devonshire St., Boston, is engineer.

Michigan

CADILLAC — The Cadillac Lumber & Chemical Co. has plans under way for the erection of a new plant at Sault Ste. Marie, Mich. The present works will be removed to this location.

MT. PLEASANT—The National Portland Cement Co. is completing plans for its proposed new 2-story cement manufacturing plant at Coldwater Lake, Mich., and will commence erection in April. It is estimated to cost about $500,000, including machinery. H. C. Shields is general manager.

ALPENA—The Kelley Island Stone & Lime Co. has acquired the plant of the Great Lakes Stone & Lime Co., at Rockport, and plans for extensive operations at the property. The present plant consists of two crushers, with total capacity of about 12,000 tons per day of 10 hours. The site comprises approximately 1,500 acres of property.

DETROIT—Plans are being completed by the Board of Water Commissioners for the construction of a filtration plant for the city waterworks at Waterworks Park, estimated to cost in excess of $2,000,000. Theodore A. Leisen is engineer. H. S. Starkey, 176 East Jefferson Ave., is secretary.

KALAMAZOO — The Kalamazoo Paper Box Co. has commenced the construction of a new plant to cost in excess of $150,000, including machinery. Robert E. Staebler is secretary, treasurer and general manager.

Missouri

KANSAS CITY—The Fleischmann Yeast Co. has acquired the plant of the Liberty Yeast Co., at North Kansas City, now in course of erection. It will be completed at once, with estimated cost of about $350,000. The factory will have a daily capacity of about 15,000 lb. of yeast.

ST. LOUIS—A large filtration plant will be installed at the city waterworks in connection with a number of extensions and improvements, estimated to cost in excess of $5,000,000. An election to vote bonds will be held during the summer. Edward E. Wall is city water commissioner.

New Jersey

TRENTON—Fire, Feb. 17, destroyed the plant of the Vulcan Recovery Co., May and Beakes Sts., manufacturer of reclaimed rubber products, with loss estimated at about $100,000, including equipment.

New York

SYRACUSE—The Syracuse Pottery Co., 711 East Division St., has tentative plans under consideration for the erection of a new plant at Amboy, near Syracuse.

BROOKLYN—J. M. Huber, 602 62nd St., manufacturer of colors, is taking bids for the erection of a 2-story plant addition, 36 x 52 ft., at 62nd St. and 6th Ave.

North Carolina

HENDERSONVILLE—A filtration plant will be installed at the new city waterworks, estimated to cost about $400,000, complete. Bonds have been issued. The Gilbert C. White Co., Durham, N. C., is engineer. C. E. Brooks is chairman of the Water Committee.

SALISBURY—The Arey Brick & Lumber Co., recently organized, will install a new drier system and make other improvements at its local brick-manufacturing plant. The company will operate with a capital of $100,000. F. M. Tyack is secretary and treasurer.

CHARLOTTE—The Council is planning for extensions and improvements in the municipal water gas plant, to cost about $40,000, to include a new tar extractor and equipment to increase the output from 15,000 to 25,000 cu.ft. per hour.

Pennsylvania

PHILADELPHIA—The Moore White Co., 15th St. and Lehigh Ave., manufacturer of iron and steel castings, etc., has commenced the erection of a 2-story foundry addition, 60 x 165 ft., estimated to cost close to $35,000.

YORK—The Ford Roofing Products Co., manufacturer of asbestos roofing, is completing plans for enlargements in its plant to double the present output. Work will be commenced at an early date.

PHILADELPHIA—The Wittman Moriarty Co., 4th and Vine Sts., manufacturer of leather products, has awarded a contract to William F. Newberry, 112 South 16th St., for the erection of a 1- and 2-story addition to its tannery at Ontario and C Sts., 75 x 105 ft. Furness, Evans & Co., 315 South 15th St., are architects.

LANCASTER—The Armstrong Cork Co. has construction under way on a 1-story addition to its local plant at Mary and Liberty Sts., 30 x 50 ft.

Tennessee

MEMPHIS—The Kot-N-Wood Products Co. has work under way on a new plant on local site for the manufacture of fiber paving brick, wallboard and kindred composition products, utilizing treated waste cotton stalks as basic material. The initial brick plant will have a capacity of 3,600 bricks per hour, with building 60 x 240 ft. George B. Stryker is president. William D. Edwards is engineer in charge.

LAFOLLETTE—The LaFollette Coal & Iron Co. has preliminary plans in preparation for the erection of its proposed new fuel-carbonizing plant. Parker & Wilder, Cincinnati, O., are architects. S. S. Pratt is assistant general manager.

Texas

DALLAS—The Trinity Paper Mills Co., Commerce, Tex., operating a local pulp mill, has acquired property at 3010 Williams St., Dallas, as a site for the erection of a new 1-story plant for the manufacture of waxed paper specialties. A subsidiary company will be organized to operate the factory, with J. Y. Webb and J. M. Irwin, officials of the Trinity company, as president and vice-president, respectively.

ROCKDALE—The Douglass Drilling Co. will commence the immediate erection of a new oil refinery to handle crude oil from its Rockdale-Tracy leases. It will be built on the unit plan, with first unit to have a capacity of 15 bbl. per day. A lubricating oil and grease plant will also be established.

Virginia

WINCHESTER—The American Gas Improvement Co., 2 Rector St., New York, N. Y., is planning for extensions and improvements in its local gas plant to cost about $150,000. A new electrochemical gas-manufacturing process will be installed.

RICHMOND—A new purification and filtration plant will be installed in connection with extensions and improvements to be made to the city waterworks, estimated to cost about $1,500,000. The Water Department is in charge.

West Virginia

BELLE—The Belle Alkali Co. is perfecting plans for the erection of its proposed plant addition, to be used for the manufacture of caustic soda, chlorine and kindred products. D. W. Stubberfield is manager.

FAIRMONT—The Board of Water Commissioners is planning for the installation of a filtration plant at the city waterworks, with capacity of about 4,000,000 gal. per day. S. B. Miller is city engineer.

Wisconsin

MILWAUKEE—The Red Star Yeast & Products Co., has taken bids for the erection of a new experimental plant, 25 x 40 ft. E. R. Liebert, Milwaukee, is architect.

OCONTO FALLS—The Falls Mfg. Co. has preliminary plans under consideration for the erection of a 1-story paper mill, 60 x 200 ft., estimated to cost about $150,000, including machinery. Frank Cota is secretary.

Capital Increases, etc.

THE LOUISVILLE CEMENT CO., Louisville, Ky., has filed notice of increase in capital from $850,000 to $2,100,000.

THE DUNN OIL CO., Kansas City, Mo., has filed notice of increase in capital from $400,000 to $1,000,000.

THE MACDOUGALL PROCESS CO., Niagara Falls, N. Y., has filed notice of change of name to the Rowe Paint & Varnish Co.

THE MITCHELL-RAND MFG. CO., 18 Vesey St., New York, N. Y., manufacturer of insulation products, has filed notice of reduction in capital from $200,000 to $155,000.

THE PETOSKEY PORTLAND CEMENT CO., Petoskey, Mich., has filed notice of increase in capital from $1,500,000 to $2,500,000.

Percival Wilds has been appointed receiver for the HERCULES PAPER CORP., 135

Broadway, New York, N. Y., manufacturer of paper products, in bond of $25,000. The liabilities are stated to be $1,790,509, and book value of assets, $3,315,487. The same receiver has also been appointed for the company's subsidiaries, the FRANK GILBERT PAPER CO. and the UNION WAXED & PARCHMENT PAPER CO.

THE DURST MFG. CO., 119 Chambers St., New York, N. Y., manufacturer of rubber products, has filed notice of increase in capital from $100,000 to $400,000.

THE CALIFORNIA & HAWAIIAN SUGAR REFINING CORP., Crockett, Cal., operating a local refinery, has arranged for a bond issue of $7,000,000, for general operations. Andrew Welch is president.

THE GREEN BAY PAPER & FIBER CO. and the JOHN HOBERG CO., both of Green Bay, Wis., manufacturers of paper and fiber products, have filed notice of merger. Operations will be continued as heretofore at the two mills.

New Companies

THE SUPERIOR CRYSTAL CO., Newark, N. J., has been incorporated with a capital of $25,000, to manufacture soaps and kindred products. The incorporators are A. Leiberman, Benjamin Burden and Solomon Halperin, 109 South 20th St., Newark.

THE BAXTER PAPER CORP., New York, N. Y., has been incorporated with a capital of $100,000, to manufacture paper products. The incorporators are H. L. Bunker, I. Baxter and H. J. Wellebil. The company is represented by Graves, Miles & Yawger, 111 Broadway, New York.

THE CRAINE-SCHRAGE STEEL CO., Detroit, Mich., has been incorporated with a capital of $150,000, to manufacture steel castings and other steel products. The incorporators are C. P. Craine, Arthur A. and W. C. Schrage, 965 Devonshire Ave., Detroit.

THE MULBER OIL CO., Pawhuska, Okla., has been incorporated with a capital of $200,000, to manufacture petroleum products. The incorporators are William W. Cruber, Pawhuske; H. C. Durnell, Bartlesville, Okla.; and R. V. McMullen, Eureka, Kan.

THE AROMO MFG. CO., 740 West North Ave., Baltimore, Md., has been incorporated with a capital of $100,000, to manufacture chemicals, chemical compounds, drugs, etc. The incorporators are Arthur W. Smith, Norris Bernstein and Albert Paltieloff.

THE RAY D'OR CHEMICAL CO., Scranton, Pa., has been incorporated with a capital of $10,000, to manufacture chemicals and chemical byproducts. J. Harold Clarke, Scranton, is treasurer.

THE FAIRFIELD SHEET GLASS CO., Wilmington, Del., has been incorporated under state laws with capital of $800,000, to manufacture glass. The company is represented by the Corporation Trust Co. of America, du Pont Bldg., Wilmington.

THE BERGEN LABORATORY PRODUCTS CO., 142 Market St., Newark, N. J., has filed notice of organization to manufacture chemicals and chemical compounds. The company is headed by Joseph F. Papscoe, 800 South 19th St., Newark.

T. A. DESMOND & CO., INC., New York, N. Y., has been incorporated with a capital of $600,000, to manufacture rubber products, gutta percha goods, etc. The incorporators are T. A. Desmond, H. S. Delanie and F. M. Tienken. The company is represented by Murray, Prentice & Aldrich, 37 Wall St.

THE INTERNATIONAL REFINING & MFG. CO., Greenleaf and Hartrey Sts., Evanston, Ill., has been incorporated with a capital of $500,000, to manufacture refined petroleum products. The incorporators are E. R. and William O. Jeffery, Sr. and Jr.

THE WHITE CO., 206 Water St., Baltimore, Md., has been incorporated with a capital of $100,000, to manufacture chemicals, varnishes, paints, etc. The incorporators are I. and Earl A. Constam, and G. M. Stengle. The company has plans under way for the erection of a new plant.

THE VIRGINIA SOUTHERN OIL CORP., Wilmington, Del., has been incorporated under state laws with a capital of $750,000, to manufacture petroleum products. The company is represented by the Corporation Service Co., Wilmington.

THE MELITE CORP., New York, N. Y., has been incorporated with a capital of $25,000, to manufacture carbon black, compounds, etc. The incorporators are J. M. Stower and J. C. Woodruff. The company is represented by H. G. Baker, attorney, Plattsburg, N. Y.

THE ARCHER PHOSPHATE DEVELOPMENT CO., Archer, Fla., has been incorporated with a capital of $75,000, to operate phosphate properties, manufacture fertilizers, etc. W. F. Walker is president, and S. G. Moyes, vice-president, both of Archer.

THE S. & S. MFG. CO., Columbia, Pa., has been incorporated with a capital of $10,000, to manufacture iron, steel and other metal castings. Samuel A. Stape, Columbia, is treasurer.

THE SYRACUSE CONSUMERS' OIL CO., Syracuse, N. Y., has been incorporated with a capital of $50,000, to manufacture oil products. The incorporators are H. F. Schoonmaker, W. A. Wright and L. C. Helms. The company is represented by J. B. Neily, Gurney Bldg., Syracuse.

THE LUMINITE CORP., Newark, N. J., has been incorporated with a capital of $100,000, to manufacture chemicals and chemical byproducts. The incorporators are Carl T. Fregens, M. Burgesser and John A. Bernard, 753 Broad St., Newark.

THE CELLULOSE PRODUCTS CO., INC., 1119 Fidelity Bldg., Baltimore, Md., has been incorporated with a capital of 100,000 shares of stock, no par value, to manufacture pyroxylin products, composition specialties, etc. The incorporators are Edward M. and E. H. Hammond, and R. Bennett Darnall.

THE BRAZOS VALLEY OIL CO., New York, N. Y., has been incorporated under Delaware laws with capital of $6,000,000, to manufacture petroleum products. The company is represented by the United States Corporation Co., 65 Cedar St., New York.

THE POMPEIAN ROMANZA CORP., Fayette and 11th Sts., Highlandtown, Baltimore, Md., has been incorporated with a capital of $1,760,000, to manufacture edible oils, compounds, etc. The incorporators are W. W. Cook, W. H. Hamilton and W. H. Cook.

THE PRESTO LEATHER PRODUCTS CORP., Brooklyn, N. Y., has been incorporated with a capital of $10,000, to manufacture leather goods. The incorporators are J. Pressman, M. L. and F. Weissman. The company is represented by Leo Rosenberg, 200 Broadway, New York.

THE D. P. O'BRIEN CO., INC., Camden, N. J., has been incorporated with a capital of $20,000, to manufacture chemical compounds, drugs, etc. The company is represented by the Corporation Guarantee & Trust Co., 419 Market St., Camden.

THE DRAKE OIL CO., 30 North Michigan Ave., Chicago, Ill., has been incorporated under state laws to manufacture petroleum products. The incorporators are Frank H. Pitkin, William Mannhardt and Charles O'Hare.

THE ALABAMA MICA CO., Heflin, Ala., has been incorporated with a capital of $75,000, to operate mica properties and manufacture mica products. The incorporators are W. B. Merrill and L. L. Tapley, Heflin.

THE TRINITY OIL CORP., Jersey City, N. J., has been incorporated under Delaware laws with capital of $3,000,000, to manufacture petroleum products. The company is represented by the Registrar & Transfer Co., 900 Market St., Wilmington, Del.

THE HAMPTON ROADS EXTRACT CO., Norfolk, Va., has been incorporated with a capital of $25,000, to manufacture chemical extracts, compounds, etc. Nicholas Pavlou is president, and W. W. Ritter, secretary, both of Norfolk.

THE CARNAHAN OIL & REFINING CO., Augusta, Me., has been incorporated under state laws to manufacture refined oil products. D. A. Leland is president; and W. T. Gardiner, treasurer. The company is represented by C. L. Andrews, Augusta.

THE EASTERN CHEMICAL CO., Wilmington, Del., has been incorporated under state laws with a capital of $250,000, to manufacture chemicals and chemical byproducts. The company is represented by the Corporation Trust Co. of America, du Pont Bldg., Wilmington.

THE H. B. VITT CO., Richmond, Staten Island, N. Y., has been incorporated with a capital of $10,000, to manufacture paints, oils, etc. The incorporators are H. and C. Vitt, and W. Stumpf. The company is represented by F. W. Clifford, Stapleton, S. I.

THE ARKANSAS PLATINUM DEVELOPMENT CO., Little Rock, Ark., has been incorporated with a capital of $350,000, to operate platinum properties and manufacture platinum. The incorporators are J. E. McLean, T. W. Mattingly and C. C. Williams, Little Rock.

THE FORDS PORCELAIN WORKS, INC., Perth Amboy, N. J., has been incorporated with a capital of $1,000,000, to manufacture sanitary ware. The company will succeed the organization of the same name, now operating two plants at Perth Amboy, and one at Fords. Abel Hansen is president.

THE SURE CHEMICAL CO., Pittsburgh, Pa., has been incorporated with a capital of $100,000, to manufacture chemicals, chemical byproducts, etc. The company is represented by the Capital Trust Co. of Delaware, Dover, Del.

New Publications

THE ANNUAL REPORT of the Director of the Bureau of Foreign and Domestic Commerce to the Secretary of Commerce for the fiscal year ended June 30, 1921, has been issued.

THE UNIVERSITY OF IDAHO has issued Bull. 13, on "The Availability of Western Wood Oils for Flotation Concentration." Part I, on the Production of the Oils, is by I. W. Cook, and Part II, on the Flotation Properties of the Oils, is by Louis A. Grant.

THE BUREAU OF MINES AND GEOLOGY of the State of Idaho has published four pamphlets. No. 1 is on Interfacial Tension Measurements and Some Applications to Flotation, by Robert B. Elder; No. 2 is on Size of Mineral Particle in Relation to Flotation Concentration, by A. W. Fahrenwald; No. 3 is on Testing Ores for Flotation, by A. W. Fahrenwald, and No. 4 on Differential Flotation, by A. W. Fahrenwald.

INDUSTRIAL OPPORTUNITIES IN NEW JERSEY is the title of a new publication issued by the Land Registry, Department of Conservation and Development, State House, Trenton, N. J.

THE CITIZENS' NATIONAL BANK of Decatur, Ill., has prepared a series of illustrated folders entitled "Our National Resources." A brief description of the occurrence, mining and uses of the more important metals, salt and non-metallic elements is given in a popular manner. The illustrations are interesting and instructive. The series presents an interesting example of the application of technical information to business advertising.

THE ROYAL SOCIETY OF ARTS, London, England, has issued a pamphlet on Major G. W. C. Keye's address delivered before the Royal Society of Arts on "X-Rays and Their Industrial Applications."

Coming Meetings and Events

AMERICAN CHEMICAL SOCIETY will hold its spring meeting at Birmingham, Ala., April 4 to 7, 1922.

AMERICAN ELECTROCHEMICAL SOCIETY will hold its spring meeting in Baltimore, April 27, 28 and 29, 1922. Headquarters will be at the Emerson Hotel.

AMERICAN FOUNDRYMEN'S ASSOCIATION will hold its next convention and exhibit at Rochester, N. Y., during the week of June 5, 1922. Meetings will be held in the spring instead of in the fall as heretofore.

AMERICAN SOCIETY FOR STEEL TREATING will hold a sectional meeting, Friday, March 3, at the Hotel McAlpin, New York City. A sectional meeting will also be held at the Bureau of Mines auditorium, Pittsburgh, Pa., on May 25 and 26. The International Steel Exposition and Convention of the society will be held in the General Motors Bldg., Detroit, Mich., Oct. 2 to 7.

AMERICAN SOCIETY FOR TESTING MATERIALS will hold its twenty-fifth annual meeting June 26 to July 1, at Atlantic City, N. J. Headquarters will be at the Chalfonte-Haddon Hall Hotel.

INTERNATIONAL UNION OF PURE AND APPLIED CHEMISTRY will hold a meeting at Lyons, France, June 27 to 30.

IRON AND STEEL INSTITUTE (British) will hold its annual meeting on May 4 and 5 at the House of the Institution of Civil Engineers, Great George St., S. W., 1, London.

NEW JERSEY CHEMICAL SOCIETY holds a meeting at Stetters Restaurant, 842 Broad St., Newark, N. J., the second Monday of every month.

STAMFORD CHEMICAL SOCIETY, Stamford, Conn., holds a meeting in the lecture room of the local high school on the fourth Monday of each month, except June, July, August and September.

The following meetings are scheduled to be held in Rumford Hall, the Chemists' Club, New York: March 10—American Chemical Society, Nichols Medal; March 24—Society of Chemical Industry, regular meeting; April 21—Society of Chemical Industry (in charge), American Electrochemical Society, Société de Chimie Industrielle, American Chemical Society, joint meeting; May 5—American Chemical Society, regular meeting; May 12—Société de Chimie Industrielle (in charge), American Chemical Society, Society of Chemical Industry, American Electrochemical Society, joint meeting; May 19—Society of Chemical Industry, regular meeting; June 9—American Chemical Society, regular meeting.

Proving An Obsession

SENATOR KING, attacking the American dye industry, apparently bases his major charge upon the assumption that there is a monopoly in the American business. He cites as evidence the two great producers of organic chemicals in the United States, the du Pont and the Allied Chemical & Dye organizations. It is absurd on the face of it to charge monopoly when there are two or more great competing groups of industrial interests. These two the Senator admits; and if he were better advised regarding the business, he would know of other well-established active competitors of these two corporations. It is little but an obsession on the part of a vigorous opponent of the industry which brings forth such a charge.

This position of Senator KING is perhaps the most favorable one which he could have taken. In any event it gives a splendid opportunity for developing the real economic and industrial side of the case, as well as the technical problems involved.

In striking contrast to this attitude of the Senator is the very frank response which the principal representatives of the chemical industries are making before the investigating committee. Mr. GARVAN has promised on behalf of the Chemical Foundation and others that every document or needed person will be at the service of the committee without subpœna. The industry and its representatives know well that a thorough public presentation of the facts, not only of dye manufacture but also of dye import, cannot be harmful to the American industry. It is fortunate, indeed, that a frank spirit is thus made evident at the very start of the investigation.

Helium and The Roma Disaster

DOUBTLESS many lessons are to be drawn from the disaster that overtook the Roma and brought death to thirty-four persons engaged in the development and operation of lighter-than-air craft. The lack of helium has been blamed for much of the trouble, probably too much, although it should have been used in this ship. And the United States can no longer be held guiltless if it continues to permit training in the lighter-than-air service in hydrogen-filled bags. We have the helium—2,300,000 cu.ft. of it—or more than twice enough to have filled the Roma. It has been alleged that helium was not used because the Roma was an old ship with leaky fabric, from which the precious helium would have escaped. By what curious distortion of values does the government place helium above the lives of those who are "merely in training"?

Of course we realize that helium would not mitigate all the dangers of lighter-than-air travel and that mechanical failures have been primarily responsible for the terrible disasters that overtook the ZR-2 and the Roma. But in both cases death and destruction due to fire would not have occurred had there been a non-flammable gas in the bags. A sane program for our lighter-than-air service will abandon training in second-hand ships filled with hydrogen. It will provide for the use of helium even in training. And finally it will grant the Bureau of Mines sufficient money and talent to make the necessary fundamental scientific studies on helium and for the ultimate erection of plants for the recovery of the gas.

The recent disasters point to the necessity of recovering helium not only for the conservation of a natural resource but as a measure of humanity in safeguarding those who are devoting their lives to the conquest of the air. Let's have no more disasters in which a flammable gas adds horror to a mechanical failure. We may not be able to foresee the break of a rudder or the buckling of a frame member, but we do know that hydrogen will burn and that it is likely to take fire in almost any disaster that can overtake a lighter-than-air ship.

A German Chemist's View Of Conditions in America

THERE has lately been sent to us a reprint of an address made by an eminent German chemist who spent a considerable number of years in the United States but who returned to Germany before the war and settled down there as managing director of an important chemical enterprise. Last year he visited this country for the first time in 13 years, and he gave his impressions in November at a meeting of the "Verein zur Wahrung der Interessen der chemischen Industrie Deutschlands." He is a typical German of the cultivated class in industry; competent, able and faithful to his obligations as he sees them. He speaks English fluently.

He confirms his earlier impressions of the United States as the land of great contrasts, or, more correctly said, of great antitheses. He is impressed with the vast number of automobiles, with the high wages that are still paid, with the number of men out of work and the threats of collision between labor and capital. He draws an interesting comparison between the efficiency with which HENRY HOWARD, a chemist, trained officers for the mercantile marine, and the débâcle of American shipping that has followed the Armistice. Prohibition comes in for extended discussion, and from this he proceeds to an observation made by a chauffeur on a trip from Niagara Falls to Buffalo. At the time a plebiscite was about to be taken as to whether or not Niagara Falls should adopt the commission form of government, and billboards were plastered with arguments pro and con. He asked his chauffeur if he favored the commission form. "No," said he, "I'm against it. They all steal from the city; formerly there were thirteen who got the pickings, and now they propose to reduce the

number to five. I'm in favor of letting as many as possible get something out of it." That was abundant evidence for the German mind. "I could offer nothing against this argument," said the speaker. "I held my peace and thought of the former conditions bei uns in Deutschland, of the blessings that democracy has brought us already, and of what it has yet to vouchsafe us." From a former dyed-in-the-wool Prussian Royalist, that observation about the blessings of democracy seems a little strained, but maybe it was not.

Of greater interest are his comments on the friendly disposition of Americans toward Germany and Germans. He takes pleasure in announcing that *this grows in favor as their relations with England and France grow worse.* He cautioned his hearers, however, to avoid any awkwardness in *aiding such convalescence* (Gesundungsprocess) but rather to await its natural development. There speaks your true German! The willingness, the desire, to profit by ill-will and hatred among others remain, but wisdom counsels caution as to the methods.

It is worth while to pause right at this point lest we fall into hypocrisy. The Gospel of Hate was indeed the very shibboleth of the old German Foreign Office. To foment strife among others is the easiest way to conquer them. It is also very practical. There is no question that it has been for many years the German method. It is terribly destructive and harmful, but at the same time very profitable. Until, however, we can feel ourselves wholly free from the practice it is best not to get angry over it. Our business is to resist the lure and to make the best we can of things as they are. To do this is no angelic virtue; it is merely being decent in bad times.

A curious chapter has to do with the persistent German obsession about British control of American newspapers. Lord NORTHCLIFFE'S "influence" over twenty-seven daily publications is demonstrated by his cable news connections, and the speaker learned from "authority" that while the New York *Times* paid only 3½ cents a pound for Canadian paper "the well-known owner of the New York *American*, HEARST, the paper for the by him controlled 19 Zeitungen only at 13 cents the pound could buy. His refusal, himself into the service of the Entente to place, must have cost him $11,000,000 during the war, whereas the *Times* saved every year $360,000 on the cost of paper." The quotation, which for prudential reasons we have made as literal as possible, carries the suggestion that NORTHCLIFFE controls the Canadian paper manufacturers who refuse to sell to HEARST.

The speaker waxed very warm in his denunciation of the confiscation of German chemical patents and was persuaded that this "theft" would in time be made good, either to the former owners of the patents or by the United States Government to that of Germany.

The automobile works of HENRY FORD made a deep impression and the fundamental principle that "The laborer never waits for work, but the work always waits for the workman" is one which he commends to German manufacturers. He noted also in the power plant that with each electric generator there is coupled a two-cylinder gas engine that works at full load together with a tandem compound steam engine that meets the peaks and valleys.

He was not hopeful of a favorable revision of the tariff for German goods, especially German-made chemicals. Despite the disadvantages of high wages and prices, he thought that in this respect, as indeed often occurs, absurdity (Unvernunft) would remain the victor.

Patience, Patience, And Then More Patience

A REPORT of 1919, lately published in the *Journal of Commerce and Commercial Bulletin* of New York, estimated the loss to labor through strikes during the year at $750,000,000, and the loss to industries as $1,250,000,000, all right here in the United States.

The majority of strikes are called by men in occupations that can scarcely be designated as trades. A job that may be learned in a week or in a day or so or in a forenoon is not a trade. That is manual labor that does not require thinking to perform. It is the kind of work into which those men and women drift who are feeble of mind or will. They weigh a great deal when they go out on strike because they are parts of an organized whole, but they could all be replaced without much interruption by other willing workers. Indeed in most cases the output would be increased by *willing* workers. They are entirely different from skilled mechanics, who also strike, but who usually do so for a definite purpose. Skilled mechanics plan their walk-out carefully, and they know what they want. Usually they keep their agreements. The unskilled, however, so far as a vast number of their members are concerned, follow out like sheep. They don't think, because they can't. They can't co-ordinate. Like the student K of whom we told lately, they have a mental age of 10 or 12 years. What they call thinking is being led. "I made up my mind to walk out," says one, when he did not make up his mind at all. He means that his tropisms were responsive to the stimulus. He couldn't help going on strike.

These mental children are scarcely to be blamed for breaking their agreements. We do not hold a child of 10 or 12 to a signed contract. Why should we make an infantile striker's muscles and his long pants responsible for what he has not got in his head?

Somehow, some way, some new approach must be discovered. There's no use in fooling ourselves with the belief that the mentally undeveloped are the same as other men. They do not constitute the whole of unskilled labor, and even among those that appear hopelessly stupid there are those who may have undeveloped resources, that if aroused, would place them, in one or more single respects, far beyond the rest of us. CLAUDE LORRAINE was held to be a half-wit until one day he took a canvas and some of his master's brushes and paints along with him and came back with a picture. After that Cardinals and Princes pressed for admission to his studio. We do not know what the fraction is of the undeveloped or moron class. We know they are there, however, and that they do not and cannot understand the nature of an obligation. If they commit perjury, they are like a child who thinks itself immune because it has its fingers crossed.

They are entitled to life, liberty and the pursuit of happiness. But they should be known and placed in yard gangs or at work of a sort that will not land them into positions of trust and responsibility by virtue of seniority. If they organize into unions, they should not be permitted to strike save under the approval of some senior body or committee or organization that requires mental responsibility and character for its membership. Maybe the psychologists will help out some day. As it is, the situation is as though we were to ask a child to leave its maypole dance and come over to steer a ship.

A Plea for Chemical Economics

IN HIS ADDRESS at the International Meeting of Chemical Societies in the Great Hall of City College last September, Sir WILLIAM POPE urged chemists to bear in mind that there is great wealth yet to be obtained from the soil. Nature has a way of working silently, without coal consumption—that is, without requiring coal from the mines—and without charging for time by the hour. She synthesizes according to local conditions. Not only do plants grow and secrete exactly what we want, but micro-organisms are available to do far more than to produce alcohol and carbon dioxide. These also work 24 hours a day and they know just what they need to complete their cycle of existence, whereby we may profit. Professor HIBBERT of Yale has long been urging the slogan, "Let the Microbes Do Your Work for You!" Lately Dr. E. J. RUSSELL of Rothamsted has written of "Soil Conditions and Plant Growth" in a Rothamsted monograph published by Longmans, Green & Co., of London. His observations on conditions affecting plant growth are reported to be of wide general interest.

Our readers may recall an incident that occurred several years ago. A Mr. ECKERT, who was manager of a sugar plantation in Hawaii, was troubled by weeds. The rainfall is especially heavy there. The cost of labor in weeding ate up the profits. He bethought himself that the young sprouts of sugar cane were sharp and stiff, whereas the weeds were not. He softened roofing felt with caustic soda, laid it over the young sprouts, which pierced through or buckled under, making a visible hump which could be easily cut through later on. The weeds curled up and died. He saved 75 per cent of his labor costs and got 25 per cent better crop by it. Then he came on to Dr. LITTLE and got him to work out a soft, easily piercable bagasse felt, which served in the place of the building felt. Then he put up a paper mill for his company in Hawaii—and the outfit works very successfully. Mr. ECKERT patented his invention.

Sir WILLIAM wondered whether, if the same measure of scholarly and intelligent study had been addressed to the production of indigo from natural sources as was given to the synthesis of the product from coal tar, the artificial product would have replaced that produced on plantations properly administered. The beet-sugar industry worries along under tariff protection which it always needs, but has the last word been said in regard to sugar beets? Has the maximum been reached in growing sugar cane? Have we exhausted the product of sumac? What is the cheapest source, besides molasses, for the production of ethyl alcohol? Will it come from the intensive production of corn, and if so, what kind of corn? Where is the incidence of diminishing returns in the intensive growing of corn? What are the possibilities of cassava? How about a strain of potatoes more abundant in starch, irrespective of its eating qualities?

Industry is constantly providing new solvents. What are we doing with them in relation to natural products?

These are questions in chemical economics and the answers are not available, because we neglect chemical economics. The reason is, we do not fit ourselves to take a comprehensive view. What is needed is more co-ordination among chemical engineers and biochemists and botanists, all working together, understanding one another, and using the same scientific language in discourse. It is time for chemists to quit playing on a fiddle with one string, whether that string be organic or colloidal or metallurgical or biochemical or what not. We recommend to the American Chemical Society a committee on co-ordination which shall have for its purpose the bringing of specialized chemists out of their ruts. The great merit of the Society is the multiplicity of its divisions and sections. Why not mix 'em up? It would be a good thing all around.

What Does the Steel Recovery Mean?

AFTER extensive liquidation of stocks of steel in the hands of steel buyers, and of manufactures of steel in the hands of makers and distributors, a liquidation that was claimed to have been practically completed by the beginning of last October, the rate of steel ingot production rose to a rate of 23,000,000 tons in October and November, declining to a rate of 16,000,000 or 17,000,000 tons in the last week of December.

Now we have a remarkable fact, that the rate of steel ingot production has risen, in approximately 2 months, to about 29,000,000 tons a year. That is a fact. What does it mean?

To account for this rise in steel production in such a short space of time one might refer to the fact that production of steel ingots in July, 1921, was at the rate of only about 11,000,000 tons a year, while in the first 9 months of 1920 the rate had fluctuated but little from an average of 42,000,000 tons a year. The one rate was scarcely more than one-fourth of the previous rate. The extremity of the decline was explained on the ground that consumers were using up stocks. However, if that suggests an explanation to the recent rise, there is an admission that buyers of steel have been replenishing stocks lately, which is denied by both parties.

Is the steel industry overbuilt or not? Most observers claim it is. The capacity in ingots is between 50,000,000 and 55,000,000 tons a year, this being indicated by taking the actual production in 1916 and allowing for increases since, the estimate being supported by the fact that when greatly handicapped by various physical disabilities the industry produced during the first 9 months of 1920 at the rate of 42,000,000 tons a year. The capacity is fully double that of 1910, when a production of 25,000,000 tons kept domestic consumers quite busy working up the steel and allowed a considerable tonnage to be exported.

Against the contention that the steel industry is overbuilt it is urged in some quarters that an excess capacity over normal requirements is needed to carry the peak load. This sounds nice in theory except for the expense of carrying the extra capital investment and the difficulty in finding labor when men are busy consuming steel, but it presents an awkward situation when one recalls that before the war steel producers used to say it was impossible to advance prices unless the industry was operating at not under 80 or 85 per cent of capacity, while present prices are claimed to be far below cost of production and in some cases to be no more than cost less overhead. An industry is not very well fixed if it can get its prices only up to cost when running at peak load.

If the steel industry is overbuilt and the buying in the past few weeks has represented actual consuming requirements, business in the United States is in very fair condition indeed, even if the steel industry is not. A few weeks' time will tell, in all probability, what the actual condition is in steel with respect to business in general.

Italian Chemical Industries

From Our Special Correspondent

Genoa, Italy, Feb. 7, 1922.

JANUARY was a very difficult month for the Italian chemical industry owing to the following economic factors: (1) Suspension in the payments of a large bank, (2) the continued scarcity of electric power, (3) a considerable fall in the foreign exchange, and (4) a reduction in the demand, as well as lower prices, especially for the commoner products and fertilizers. The coming spring will, however, improve matters because the exhaustion of stocks in many quarters will necessitate the production of goods of all sorts.

Sulphur Industry

In order to avoid the damaging of crops on the isle of Sicily through the continued action of sulphur-dioxide fumes, the Italian Government issued special regulations requiring that the burning of sulphur on this island, or elsewhere, be conducted at least 100 meters from cultivated properties, and that all possible precautions be observed for avoiding atmospheric pollution. The sulphur mines continued their campaign for reducing manufacturing costs of crude sulphur, pointing out that the deficient means of transportation between the mines and the coast resulted in freight rates as high as 100 lire per ton. The necessity of developing the water power and increasing the number and capacity of the hydro-electric plants was urged as a relief for this situation. A further reduction in the prices of the different sulphur products was noted, owing to the scarcity of demand on the part of Italian and foreign clients.

Tartaric Acid and Tartar Materials

Italian tartaric acid and cream of tartar producers brought forward a motion to the Italian Chamber, insisting on the application of a much higher export tax on raw tartar, pointing out that the present price permitted foreign manufacturers to produce the finished tartar products cheaper than is possible in Italy, due to the high cost of Italian labor, transportation and coal.

The largest works producing tartaric acid and tartrates have their headquarters at Agnano, Barletta, Milan and Casale. An export tax of 22.50 lire per ton was placed on raw tartar for assisting the development of the manufacturing industry before the war, being raised recently to 50 lire (10 gold lire). An export tax of 100 lire (20 gold lire) is now proposed in the case of raw materials containing up to 50 per cent of potassium bitartrate, and of 160 lire (32 gold lire) in the case of raw materials containing more than 50 per cent of this compound.

During the first 6 months of 1921 the exports of raw tartar reached 1,268 tons, as compared with 4,467 tons in 1920 and 1,724 tons in 1919 during the corresponding period; the countries of exportation being France, Germany, England, Holland, Switzerland and the United States, this last country being the most important importer of raw tartar (650 tons). The imports reached 29 tons, against 91 tons in 1920 and 2 tons in 1919.

The higher prices demanded by Italian producers of tartaric acid brought a marked reduction in the exportation of this product. During the first 6 months of 1921 only 834 tons was exported, compared with 1,415 tons in 1920 and 633 tons in 1919 during the same months. The exports of cream of tartar were also reduced, reaching 325 tons, against 355 tons in 1920 and 103 tons in 1919. The imports of cream of tartar reached only 3 tons, against 4½ tons in 1920 and 4 tons in 1919.

Copper Sulphate

The production of copper sulphate, which reached 101,000 tons in 1918, has since continued good, and would certainly have been greater if there had not been difficulty in getting raw materials. To alleviate the situation the producers demanded repeatedly from the Italian Government that they be given some of the copper left over from the war, and after some delay they obtained 1,000 tons of this, and 20,000 tons was delivered to the state railways for electrification purposes.

The exportation of copper sulphate increased con- foreign products. During the first half of the past year 2,476 tons, against 4,116 tons in 1920 and 800 tons in 1919 during the same period of time. The importations reached only 598 tons during 1921, 791 tons during 1920 and 35 tons during 1919 in the first 6 months.

Caustic Soda

The production of solid caustic soda was increased during the war from an annual average of 3,200 tons to an average of 14,000 tons, and that of strong caustic soda solutions, or lyes, from 8,000 tons to 28,320 tons. After the war, however, it had to compete against the reductions that followed through the competition of foreign products. During the first half of the past year foreign competition reduced its exportation, which amounted to only 290 tons, against 1,702 tons in 1920 and 45 tons in 1919 during the corresponding period. The importations remained high, being 4,412 tons, against 18,831 tons in 1920 and 3,669 tons in 1919.

Gold in the Ticino River

The Ticino River, a large stream flowing to the River Po in the north of Italy, has sands that contain gold flakes and grains in quantities varying from 0.25 to 6 g. per cubic meter. This metal is always combined with silver (10 per cent), more rarely with palladium, and with it, at a depth of 15 meters, is also found iron, chromium, molybdenum, nickel, thorium and radium. Proper exploitation of this sand has not yet been undertaken, but a campaign has been started to this end.

Suspension of Electric Energy in the North of Italy

Through the precautions taken to avoid waste, greater intensity of the generating plants employing coal, benzine, petroleum, heavy mineral oils and weak fuels, an increase in the water power available and the importation of 150,000 kw.-hr. from Switzerland, the quantity of electric energy available has been increased and some of the railways have resumed the use of electric current. For some time they have been compelled to use steam. However, there is still a scarcity of electric energy for industrial plants.

Developments in Hydro-Electric Plants

With the Piave S. Croce hydro-electric plant Italian engineers expect to get 140,000 electric horsepower during 1922. By 1924 it is expected this will be increased to 200,000 and by 1928 to 300,000 and more. This will be sufficient to operate all the electric plants and railways in the Veneto region. The expense of the hydro-electric plant is estimated at about 1,300,000,000 lire.

Sectional Meeting, American Society for Steel Treating

SEVERAL local chapters of the American Society for Steel Treating, from Boston to Washington, met in New York Friday afternoon and evening, March 3, for a sectional meeting of the society. It is planned to hold three of these gatherings at various centers during the year, in addition to the regular annual convention. At least two aims may be accomplished. First, to give members who have not the opportunity to go to some far distant general convention the privilege of meeting men from other localities and discussing everyday problems with them. Second, directors' meetings will be held during the sectional meetings, thus permitting the general executives of the society to appraise local sentiment without an excessive amount of travel.

If the New York meeting may be taken as a criterion, the plan is excellent. About 100 out-of-town members registered, which, with an equal or greater number of men from the metropolitan district, gave an interested attendance at meetings which would have done credit to many an older society. Thanks to the indefatigable work of Captain Walter C. Graham of the program committee, all but one of the papers had been obtained in time for publication in the February *Transactions*. Members were therefore appraised of what was to be said, and the discussion was correspondingly animated.

A pleasant feature of the evening program was the notification of Dr. John A. Mathews, of the Crucible Steel Co., of his election to honorary membership.

Manufacture of Stainless Cutlery

The one paper not readily available in the published *Transactions* was read by R. G. Hall, of R. Wallace & Sons Manufacturing Co., on "The Manufacture of Stainless Steel Cutlery." He recognized that authorities differ on many essential points, but nevertheless desired to record his personal experiences. For cutlery, carbon should range between 0.3 to 0.45, and chromium from 13 to 15 per cent; silicon 0.30 and manganese 0.50. Although the tendency is for higher carbon and chromium steels, higher carbons produce a steel which punishes cutting dies excessively and is therefore costly to use; as carbon goes up, chromium must also increase in order to resist corrosion. Cutting efficiency —determined by cutting wooden chips on a lathe and noting the time before it is necessary to hone the edge —also increases with high alloying, as may be shown by the last steel in the attached table (a steel, by the way, which cannot be manufactured into cutlery by the methods to be given below). Staining liquid used was concentrated acetic, tartaric and hydrochloric acids.

TABLE I—COMPARATIVE TESTS ON STAINLESS CUTLERY

Analysis		Time to Stain	Cutting
Carbon	Chromium	Minutes	Test
0.30	11.93	28	Good
0.26	17.21	35	Fair
0.40	13.60	13	Good
0.31	15.90	75	Good
1.10	23.32	43	Extremely good

One general precaution is to pay great attention to the tools—a die which is the least bit dull will tear the stock ever so slightly; the resulting damage will not be apparent until the blade is nearly finished. Seamy blades are usually ascribed to poor steel, but in most cases are caused by metal torn during fabrication. Second, even with sharp tools it is also necessary to keep the metal well softened, "annealed" as it is called in the shop, although "tempered" would probably fit the operation better, since it involves a slow cooling from a soaking heat at 1,400 deg. F. (below the critical). Thirdly, all heating should be done in reducing atmosphere, and every precaution made to keep the metal free of scale at all times.

Manufacturing operations are somewhat as follows: The "annealed" stock, which is usually bought in round rods, is cut to proper length, drop forged, trimmed, and the blade rolled. Careful temperature regulation between 1,650 and 1,750 deg. F. is essential for the latter, on account of the abrupt change of section at the shank. Scale must not be rolled into the blade, nor should it be permitted to cool rapidly, as on a damp floor. Premature hardening causes internal strains and cracked articles. Next the forged and rolled piece is softened at 1,380 to 1,400 deg. F. in a muffle, slowly cooled, and the blades are blanked out, using *sharp* tools.

Now follows the hardening, which is the most difficult part of the operation, affecting not only the cutting qualities of the knife, but also its resistance to strain. For several "practical" reasons Mr. Hall prefers to quench in oil from 1,650 to 1,950 deg. F., depending upon the composition, although he recognizes that the British practice is to water-quench, and no difference in microstructure is discernible. The hardened blade is then tempered so that when loaded centrally it will bend 1 in. in 5 without a set, and have a Brinell hardness of 525 to 550. Time and temperature are adjusted to the steel for this result. Commonly 15 minutes at 650 deg. F. is correct. Since temper colors appear in heated stainless steel at about twice the heat of carbon steels, and are also unreliable, a bath should be used.

Grinding should be done without haste. Heavy grinding induces staining—the first evidence is "grinders' scorch," which polishes off easily enough but leaves an area which stains again very easily. It is also necessary to grind to the bottom of all pits and surface imperfections, since a minute amount of adhering mill scale will cause delayed staining and many complaints after blades have been in satisfactory service for months. Cutlery is then glazed on a fine wheel to remove grinding marks, inspected, mounted in the required handle (soldered to hollow handles, welded to solid ones), again glazed and tested for stainless qualities by immersion for 2 minutes in concentrated copper sulphate solution. Finally the accepted knife is etched, wrapped and stocked.

Magnetic Testing of Chain

A brief paper on this subject read by A. V. de Forest, research engineer, American Chain Co., proved exceptionally interesting, since the author had brought with him the electrical equipment and sample chains necessary for making the required tests.

Anti-skid chains are exposed to extremely severe service, and it has been found on road test that a certain depth of hardened case gives longest life; shallow cases are too soft, while deep ones are too brittle. Magnetic testing has proved of extreme value in promoting uniformity of product; if road tests indicate that a certain stock, carbonized and heat-treated in a certain way, will give superior wearing qualities, then the magnetic test may be relied upon to hold the mill production as close to this given ideal as desired. Or, if all manufacturing conditions but one are held constant, the magnetic test will very sensitively indicate values of that variable.

Electrical Porcelain Manufacture

Description of the Plant and Operations of R. Thomas & Sons at East Liverpool, Ohio — Production of Ware for High- and Low-Voltage Uses—Raw Glazes Employed—Body Similar to Chemical Stoneware—Ceramic Control

BY CHESTER H. JONES

THE 12-kiln plant of R. Thomas & Sons, manufacturers of electrical porcelains, is well located in East Liverpool, Ohio, for while the ultimate product and markets are different from tableware, the operations in the plant are essentially those belonging to the white ware pottery. The labor market is also best at this point. The plant produces a general line of insulators for low- and high-voltage electrical construction, while the 10-kiln plant at Lisbon, Ohio, is devoted to the manufacture of the patented Hewlitt insulator. The Lisbon plant was originally built to manufacture tableware.

R. Thomas, together with his son, the late George W. Thomas, organized the present company in 1873, building the first plant in East Liverpool. It was the first firm in the United States established for making high-voltage porcelains. Low-voltage porcelains are made by the dry process, where the dried cake from the filter press is ground to powder and compressed in heavy molding machines. High-voltage porcelains follow the method of molding the plastic clay employed in chinaware plants.

Storage and Blunger House

The raw materials used are kaolin or English china clay, English ball clay, flint or ground silica, feldspar, barium carbonate, magnesium carbonate and calcium carbonate. Raw white glazes are made up of these materials, no frits being used. Colored glazes are made from Albany slip, feldspar and flint. The top of the raw storage piles and blunger house is on a level with the incoming railroad tracks. The materials are delivered from cars to storage by an endless belt and tripper to four of the seven concrete bins and direct by shovel to the remaining three.

Fig. 1 is a view in the aisle of the blunger house. On the left are the blungers with feed openings nearly on a level with the Fairbanks transfer table scales appearing in the center. This weighing outfit is so arranged that the scale car can be wheeled into each concrete raw material bin for loading. The doors of two of these bins are seen on the right. A blunger charge for the wet process slip weighs 5,400 lb. and for the dry process 6,500 lb. There are four blungers, consisting of steel tanks lined with vitrified brick and equipped with double agitators. The line shaft driving the blungers through bevel gears is in turn driven by a 20-hp., 220-v., two-phase motor.

FIG. 1—TRANSFER SCALES

FIG. 2—SLIP PUMP AND BLUNGERS

Three blungers operate on the wet-process slip, the remaining one on the dry-process. The charge is blunged 1 hour to give the necessary creamy slip. Three agitated storage cisterns below the floor receive the slip from the blungers. The three blungers deliver into two of these, while the third receives the dry-process slip from one blunger.

Fig. 2 is a view on the delivery side of the blungers, with the wet-process double-acting slip pump in the foreground. This pump delivers wet-process slip from the two cisterns to the lawn room in the main buildings located up hill from the railroad. A similar pump likewise handles the dry-process slip from the third cistern to a second lawn room. These pumps are also equipped with 20-hp. Westinghouse motors.

Sagger Room

The saggers for holding insulators while burning in the kilns are made as usual in a separate department. Raw materials used for making these saggers are Kentucky ball clay, Pennsylvania sandy clay, wad clay and

grog. The equipment here consists of a small dry pan, grinder, vertical pug mill, small wad mill and a 28-ton steam press having a pressure of 250 lb. per sq.in. for forming the sagger. The wad mill is a small affair extruding a plastic clay string about ¼ in. diameter. This is used between the top edge and the lid of the complete sagger for sealing in the ware, thus preventing the entrance of kiln gases and resultant contamination of the ware.

The formed sagger from the steam press is dried thoroughly by placing over a gas flue. It is not necessary to burn the saggers in separate kilns, as often

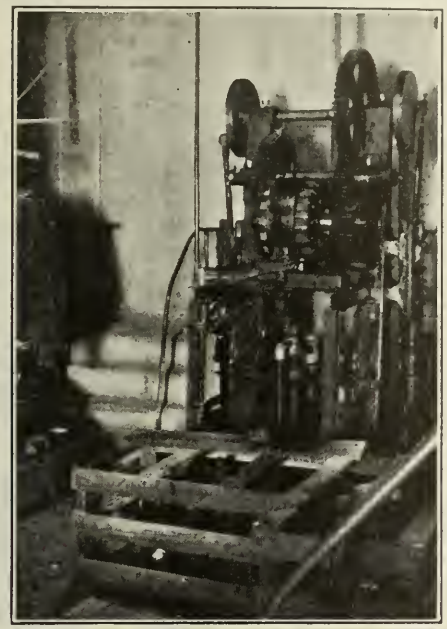

FIG. 3—LAWN ROOM PUMP

practiced. The "green" product from the drying flue may be filled and burned at the same time as the ware it contains.

Lawn Rooms

The slip for dry body or low-voltage porcelain is delivered from the blunger house as mentioned above to a cistern in the low-voltage lawn room. Thence it is pumped onto a 120-mesh lawn shaker screen and returns to a second cistern, where it is agitated until delivered by a second pump at 80 lb. pressure to the filter room.

The larger or high-voltage lawn room is equipped with two units, each consisting of a cistern receiving slip from the blunger house, a 120-mesh shaker lawn,

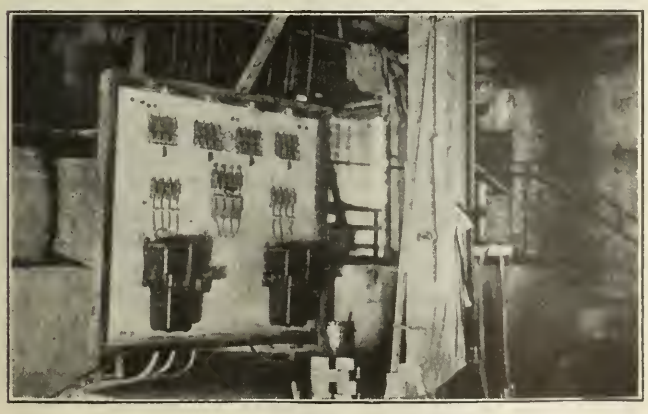

FIG. 4—LAWN ROOM SWITCHBOARD

FIG. 5—SHAKER LAWN

a second cistern and a pump delivering the finished slip to the filters. Fig. 3 shows one of the double-acting pumps in the high-voltage lawn room driven by two-phase electric motor, and Fig. 4 shows the switchboard, carrying oil switches, fuses and knife switches controlling the pump motor circuits and shaker lawn motor. The shaker lawn appears in Fig. 5.

The glazes made from white ingredients or Albany slip without frits are ground in three 1,000-lb. pebble mills adjoining the high-voltage lawn room. Fig. 6 shows a portion of one of these arranged with belt drive.

Filter Room

Production of the plastic cake from the slips as they are pumped in from the lawn rooms is carried on in one location with a battery of seven 80-lb., leaf type, Patterson filter presses. One press is used on low-voltage and six on high-voltage body. For dry-process low-voltage porcelains, the cakes from the filter press

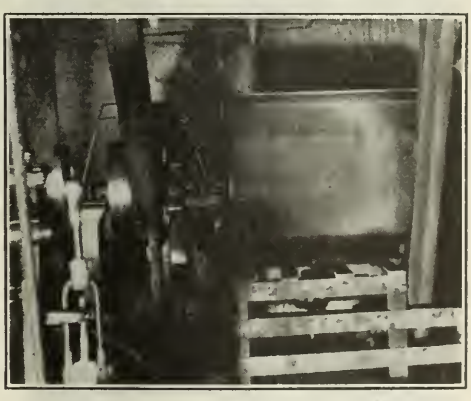

FIG. 6—PEBBLE MILL FOR RAW GLAZES

are elevated to a drying room located over the kilns and after thorough drying are pulverized and tempered for pressing to shape.

For wet-process, high-voltage porcelain the plastic cakes are piled in a heap, beaten with mallets into a solid mass and permitted to age for a period varying from 1 to 3 days. During this time the moisture becomes evenly distributed throughout the mass. Just before it is sent on to the shaping department it passes a vertical type pug mill. This operation consolidates the clay, works out any air bubbles and forms it to suitable slabs for working.

Pugging

The pug mill consists of a vertical hollow cylinder, in the middle of which revolves a shaft carrying

projecting blades. The blades, being set at an angle, gradually force the clay downward, at the same time kneading and mixing it. At the bottom of the cylinder it is forced through an opening in the side, coming out as a continuous bar from 4 to 6 in. in diameter. From this bar slabs are cut of suitable length for subsequent processes. Pugging is an important operation in the manufacture of insulators, for upon it depends the freedom of an insulator from checks and air bubbles and the consequent ratio of dielectric strength.

Shaping High-Voltage Insulators

The jigger room is equipped with about ten jiggers and several hot presses. The jigger as here employed consists of a vertical shaft revolving at a moderate speed and having at the top on a level with the workman's bench a plaster of paris mold to form the outside shape of the piece. A lump of pugged clay is dropped into the mold and formed roughly to shape by hand. The metal template, called a tool or shoe, having the contour of the inside surface of the insulator, is then pressed down by means of an arm attached to the machine and the finished interior outline given. The mold containing the shaped piece is then removed and another mold dropped into place for the next piece.

The pieces are permitted to remain on shelves in molds for 24 hours. The mold is then opened up, the piece removed and set upon boards or cars in readiness to be taken to the drier.

Hot Pressing

The hot press room contains eight hot presses, a machine similar in general characteristics to the jigger. Fig. 7 shows one of these ready for the operation.

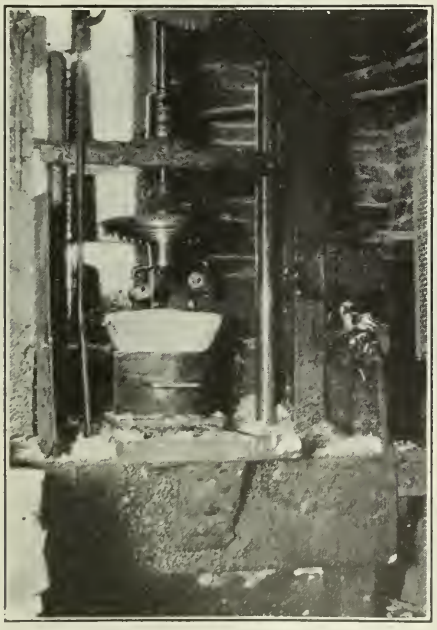

FIG. 7—HOT PRESS

Different from the jigger, the table below does not revolve, but holds the plaster of paris mold solidly in position. A circular billet of clay with one end rounded is thrown with round end down into the mold.

While the machine is in the position shown two gas flames play upon the upper cast-iron half of the mold, keeping it warm between movements. These gas burners are visible between the upper and lower halves of the mold. It will be noted that the upper half is threaded and grooved to form the inside of the insulator. The crosspiece above acts as a guide for the threaded mold shaft.

After the clay is placed in the lower half, the operator throws on power, causing the shaft to revolve, and due to threads on shaft of the same pitch as the threads on the mold the upper half moves downward quickly and enters the clay, forcing it to fill all the space between the upper and lower halves and simultaneously forming a thread on the interior of the piece. At the end of the travel the piece is thus shaped, the power is reversed and the upper half unscrews upward to its original position, to be heated again by the gas flumes.

The heating of this mold causes a film of steam to form when it comes in contact with the wet clay, giving a clean-cut surface and, still more important, permitting an immediate removal of the iron from the clay without danger of sticking. The iron mold is hollow, avoiding suction by permitting air to pass through small holes when it is withdrawn. The operation may be repeated very rapidly, the speed being entirely dependent on how quickly the lower half may be removed from the machine and a new plaster of paris mold inserted.

As in the case of jigger work, the piece is permitted to remain in the mold 24 hours before removing and transporting to the drier.

Other Shapes

The method of shaping the high-voltage pieces depends upon the article to be made. Pieces of a diameter rather large in proportion to the height, such as pin and suspension insulators, are made on the jigger or press as above described. Long corrugated pieces like bushings and post insulators are turned. This turning may be done on a special lathe or jigger. It is essentially the same as wood turning. Wet turning is most advantageous where possible because of increased speed and lack of dust.

Plain tubes are made by extrusion from a machine composed essentially of a cylinder and a piston. In the bottom of the cylinder is placed a die having a hole equal to the outside diameter of the desired tube and a concentric mandrel to form the bore. In the case of small tubes several may be extruded simultaneously. The cylinder is filled with pugged clay, the piston moves slowly down, squeezing the clay from the die in the form of a continuous tube. Suitable lengths are cut off and straightened by rolling. The head is pressed up on small tubes and spun on in the larger sizes.

Drying High-Voltage Body

All of the various pieces having been placed on rack cars after removing from the molds, these are wheeled to the entrance of the large drier as shown in Fig. 8. This drier is 104 ft. long and three tracks wide. It has a capacity of nineteen cars per track. One track handles cars containing larger ware and operates at a rate of one car entering every 3 hours, or giving a drying time on each car of 57 hours. The two other tracks carry cars of smaller ware and operate on a 2-hour schedule, consequently giving a drying time of 38 hours per car.

Proper regulation of drying rate is one of the most important features of insulator manufacture. Extreme care must be taken or cracks and warping will develop, affecting both the mechanical strength and dielectric

FIG. 8—RACK CARS ENTERING DRIER

properties of an insulator. Before the advent of the mechanically operated, automatically controlled drier in the ceramic industries it was necessary to place the ware in a heated room with little humidity control for a period of from 2 to 6 weeks.

The insulation at this plant is a Hurricane drier manufactured and installed by the Philadelphia Drying Machinery Co. The humidity and air supply is automatically controlled by wet and dry bulb Tycos regulators. Fig. 9 is a part view along the drier showing blower drive and control.

There are nine fans alongside the drier, all driven by a 25-hp. two-phase motor. Steam at 100 lb. pressure is supplied to the coils. All steam used in the plant is purchased from an adjoining factory. An air pump furnishes 25 lb. air pressure to operate the diaphragm valve on the controls. There are four sets of control mechanism for automatically handling the supply of steam and air to the drier. Pieces from the drier are conveyed to the glaze dipping room.

Dry-Process, Low-Voltage Room

Low-voltage body in the form of filter cake, having been passed through the drier on cars along with the high-voltage shapes and subsequently stored in a heated room over the kilns, is sent to the low-voltage shaping room. Here it is rough ground to nut size and mixed with just sufficient water to make a damp powder without becoming plastic. It finally passes through a plate type grinder running at 2,200 r.p.m., coming out as a fine damp powder. Two complete grinding units perform this operation.

Arriving in the press room through a chute from above, the powder is shaped in about fifty different hand presses to the forms required. The dies used in these presses are lubricated with a special oil known as Franklin XX. After trimming off the rough edges by hand, an operation known as fettling, the pieces are transported on trays to the dipping room.

Dipping Room

Both high- and low-voltage bodies are dipped by hand in tubs of wet raw glaze. The ingredients of the glaze are ground with water as previously noted. Colors are often introduced in glazes to identify electrical circuits when the insulators are in place. These include chromium, cobalt, Albany slip, a dark brown and the natural white. Before dipping in the glaze the pieces are immersed in water to remove dust which may have accumulated through the process. The dipped pieces are allowed to drain and dry in the air and are then ready for the kiln. In cases where it is desirable to roughen part of the surface of the insulator to give friction where in contact with insulator pin or for other reasons, the part is coated with paraffine, then with a mixture of sodium silicate and gum arabic and dipped in high-voltage sand. The sand adheres to the sticky surface, giving the desired roughness. The portions of all insulators which come in contact with the sagger are paraffined.

Firing

The kiln room is equipped with twelve updraft periodic kilns of 12, 14 and 16 ft. diameters. Materials and saggers are handled in and out of the kilns by Lowden overhead conveyors. When the saggers of ware are stacked in the kilns, the green or unburned saggers are placed near the top above the jack saggers.

Actual firing time varies from 40 hours on the small ware to 70 hours on the larger pieces. During the first stage the temperature is raised and the moisture is driven off. This moisture includes that merely mixed with the clay which has not been driven off in drying and also that which is chemically combined with the clay particles as an essential constituent. The latter action is accomplished at about 1,200 deg. F. and is a true decomposition of the clay substance. In the next stage the temperature is raised to proper value for the vitrification to porcelain and is held there until a heat-saturation point is reached as indicated by cone 11.

FIG. 9—VIEW ALONG DRIER SHOWING BLOWER DRIVE

This is a delicate stage. If the temperature is too low, the porcelain is underfired and porous, and if too high, it becomes brittle, full of bubbles and therefore electrically weak. During the last stage the kiln is allowed to cool gradually so that the ware is well annealed. The entire cycle requires about 5 days.

Fuel

Three of the kilns burn coal, three gas with natural draft burner and the remaining six burn fuel oil or gas. The combination burners on two of the kilns are the Maxon Premix and on four kilns are Spencer burners made by the Leader Furnace Equipment Co., Cleveland, Ohio. Fig. 10 shows the new type gas-oil burner applied through the ash door of a kiln. The oil is sprayed into the space below the firebox at a pressure of 30 to 40 lb. with air pressure at a maximum of 3 oz. The oil nozzle is cut with cross-shaped slot. Fuel oil is purchased from the Oklahoma fields and is a refining residue. The main storage tank holds 200,000 gal., with an auxiliary tank of 6,600-gal. capacity.

Fig. 11 is a view of the natural draft burner adapted through ashdoor.

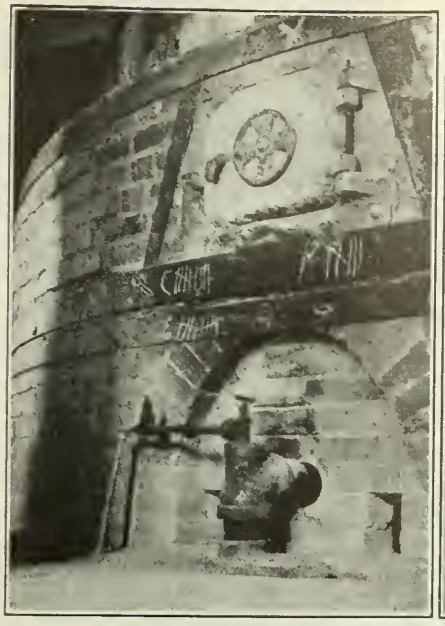

FIG. 10—NEW TYPE GAS-FUEL OIL BURNER

FIG. 11—NATURAL DRAFT GAS BURNER

An average kiln consumes about 2,000 gal. of fuel oil per burn, making a fuel cost of $70. To do the same work 220,000 cu.ft. of gas is required at a cost of $100. Twelve tons of coal at $5 per ton is used per burn, at a cost of $60 plus the cost of cleaning and ash-handling. It is obvious that oil is the most economical fuel for this plant.

Assembling

After the burning operation the insulators are sent to the assembling and testing departments. The parts of pin and suspension insulators are fastened together with portland cement mixed neat and just thin enough to flow readily. The tubes of roof and wall bushings, not being exposed to much mechanical strain, are fastened together with an asphalt compound which incidentally gives increased insulation.

Electrical Testing

Dry-process porcelain, being for low voltage, is not ordinarily subjected to electrical tests. On the contrary, the wet-process, high-voltage product must undergo not only electrical but also mechanical tests. Electrical tests which do not injure the test-piece, to determine size and proportion such as measurements of dry and wet flashover, corona voltage, etc., are usually made on a few samples. Electrical tests are made where the proportions and size are assumed to be correct and it is required to determine the limitations of the porcelain or compare with some standard.

Where the ultimate limit is to be determined, the piece is destroyed, which prevents the application of the test to more than a small fraction of the product. The puncture under oil test and the ultimate mechanical strength test are examples. The particular sample being destroyed, the only value of such tests lies in what may be inferred as to the qualities of the large proportion not tested.

Where the material is merely required to come up to a certain standard, only pieces failing to meet it are destroyed. Common examples are the routine flashover test in the pan applied to all insulators, and with suspension insulators the test load. Good judgment is required in laying out such tests. They should be severe enough to remove really defective material but not injure or weaken average or good material. This is complicated, since there is no sharp distinction between good and bad, and all intermediate grades will exist. For commercial purposes the test must be such that most of the material if of average quality will pass it, and the pieces so selected will stand the working conditions. If these features are not consistent, a design of stronger proportions must be selected.

Dimensions of Porcelain Pieces

The accuracy to dimensions of porcelain is affected by a number of factors. There is first the wear of the molds. This is important with both steel and plaster molds. The greater the variations which can be permitted the longer the life of the mold. Next comes the shrinkage in drying. This depends upon the amount of moisture in the clay, and is difficult to control very closely. Finally there is the shrinkage in firing. Of course exactness in dimensions can be obtained by gaging and rejecting all parts outside the limits, but this is scarcely possible except in the few instances in which the rejected pieces can be used for other purposes where exact dimensions are not so important. In some cases the variation can be reduced by special attention to the moisture content, by trimming after drying, or grinding to size after firing. All such methods cause added expense, and unless really necessary are avoided. Good commercial limits which do not involve any unusual precautions are a total variation from minimum to maximum of $\frac{1}{32}$ in. per inch for dry process porcelain, and $\frac{1}{16}$ in. per inch for wet process.

Shipping Room

The inspected and tested insulators finally arrive at the shipping room, where they are packed with shavings in barrels and crates. The finished package is weighed over an American Kron scale and passed into the cars.

Ceramic Laboratory

In addition to research work the ceramic laboratory controls the various operations in the plant. Moisture factors must be taken on all raw materials. Porosity and screen tests are made on clays. Chemical analysis is made on feldspar and elutriation tests on flint and feldspar. Some test must be made of the lime content of the flint.

Ball clay vitrifies at cone 11 but does not overfire, because of long vitrification range. It also has high mechanical strength. Electrical porcelain is a vitrified ware, where tableware made in this district is only semi-vitreous. Naturally the body used is difficult to dry because of high ball clay content. China clay runs more uniform and causes less trouble.

The body mixed is controlled by regular tests which effect the length of time to age, the moisture in the filter cake and the operation of the drier. The uniformity of mixture secured by aging is most important in the manufacture of porcelain. It resembles chemical stoneware in this respect.

Concentrating Dilute Nitric Acid Solutions

Results of Experimental Studies on the Concentration of Dilute Nitric Acid by Distilling at Atmospheric Pressure While Keeping the Liquid and Gas Phases in Equilibrium

By CLIFFORD D. CARPENTER and JOSEPH BABOR
Department of Chemistry, Columbia University

ZEISBERG has recently translated for this journal two articles on the concentration of nitric acid. In the first[1] Galle has considered the preconcentration of dilute acid by fractionation and its superconcentration in the presence of sulphuric acid. In the second[2] Pascal has studied the binary system nitric acid-water (Part I) and the ternary system water-nitric acid-sulphuric acid (Part II).

As a result of his experiments Galle advises preconcentration to about 65 per cent acid solution. The results given in his Table III show that he fractionated 33.8 per cent nitric acid to a strength of 65 per cent with a negligible loss either as nitric acid or by decomposition. A thermometer sealed in at the top of his fractionating column remained at 98 to 99 deg. C. throughout the experiments. When he made an attempt to concentrate farther the temperature rapidly rose and nitric acid came over in the vapor. During the last 2 years students[3] have concentrated dilute nitric acid solutions by fractionation in an apparatus identical to the one described by Galle except that the fractionating column was not as thoroughly lagged and the heating of the flask was accomplished by a bath of calcium chloride solution. It was found by them that when heated directly by the flame considerable more decomposition of the acid took place. In general it was found that the acid could be brought to about 35 per cent with very little loss of acid, but that the amount of acid in the distillate increased very rapidly as the concentration of the residue increased above this point. It would seem that Galle had an exceptionally efficient fractionating column.

TABLE I—CONCENTRATION OF NITRIC ACID BETWEEN 6.533 AND 59.72 PER CENT

Weight of Residue, g.	Weight of Total Distillate, g.	HNO_3 in Distillate, Per Cent	Total Distillate, Per Cent	HNO_3 in Residue, Per Cent	Temperature of Bath, Deg. C.
618.370	.....	.....	.....	6.533	.....
559.33	59.04	0.07	9.55	7.21	110–112
495.20	123.17	0.17	19.92	8.12	110–112
451.20	167.17	0.25	27.04	8.90	110.112
403.68	214.69	0.35	34.72	9.92	112
339.67	278.70	0.54	45.07	11.74	112
277.41	340.96	0.84	55.14	14.26	113
218.93	399.44	1.33	64.60	17.85	113
161.99	456.38	2.30	73.81	23.52	114
111.48	506.89	4.59	81.97	32.13	114
79.15	539.22	8.46	87.20	40.36	117
51.69	566.68	15.42	91.80	48.33	119
32.29	586.08	22.34	94.78	55.95	120

Pascal has studied the nature of the vapor phase in equilibrium with the liquid phase at various pressures and temperatures and finds considerable decomposition at the higher temperatures.

In connection with a study of several ternary systems which the authors are making at the present time, the binary system water-nitric acid has been briefly studied. Like Pascal, we have kept the vapor in equilibrium with the liquid phase throughout the distillation, but have considered the results in a slightly different manner. A description of our apparatus,[4] method of procedure and a discussion of our results are given below.

Apparatus

A complete diagram of the apparatus is shown in Fig. 1. The distilling flask and delivery tube is completely immersed in a bath (a solution of calcium chloride) so that the vapor will not condense until it enters the condenser. The condensed liquid then drains down directly into the receiving vessel. A glass stopcock is sealed onto the delivery tube so that there will be no loss of distillate which runs down while the flask which has received the first fraction is being replaced by a second. The detail of the apparatus is fully given in the figure. The flask and all material coming in contact with the vapor or liquids are of Pyrex.

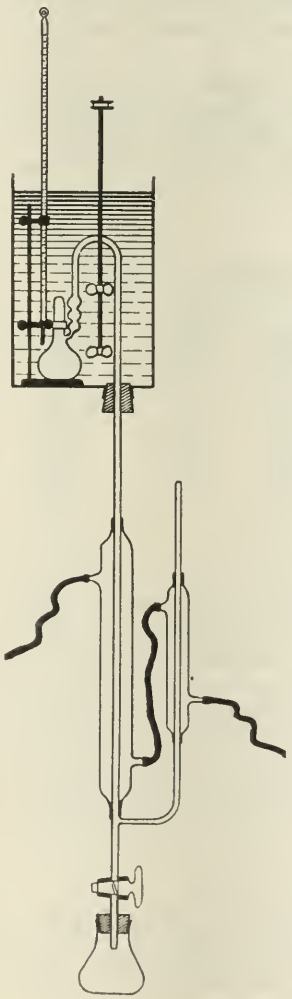

FIG. 1—DISTILLATION APPARATUS

Procedure

A quantity of nitric acid of known concentration is weighed into the flask. The flask is then introduced into the empty pot, the delivery tube led through the stopper in the bottom and then sealed to the inner condenser tube. The bath liquid is then poured into the pot until the flask and delivery tube are well covered. The bath is vigorously stirred and sufficient heat is applied to keep up a slow but continuous distillation. A fraction of 25 or 30 g. is received into a small weighed flask and removed. While a second fraction is being collected the first is weighed and titrated. In this manner a continuous experiment gives a number of values which can be expressed in such a manner that the rate

[3] Chem. 104. Advanced Inorganic Preparations.

[4] Although the apparatus and method is very similar to that of Pascal, it was designed and used 2 years ago, when this work was first started.

of concentration of the acid is known. All experiments were carried on at atmospheric pressure. The results of three experiments are given in Tables I, II and III respectively and these results are graphically expressed in Fig. 2.

In the first experiment 618.37 g. of 6.533 per cent nitric acid was concentrated to 59.72 per cent acid while the temperature of the bath changed from 110 to 122 deg. C.

In the second experiment 705.995 g. of 6.533 per cent nitric acid was concentrated to 53.25 per cent acid while the temperature of the bath changed from 110 to 124 deg. C.

In the third experiment 517.56 g. 38.518 per cent nitric acid was concentrated to 51.915 per cent acid while the temperature of the bath changed from 118 to 122 deg. C.

As has been pointed out by previous experimenters, the results become more or less unsatisfactory as the amount of distillate approaches the amount of residue. In studying the salt effect. McBain[5] used large quantities of dilute solutions and took the composition of only one small fraction as representing the nature of the vapor phase. In Fig. 2, however, we have plotted the results of our experiments on a different basis than previous experimenters and the regularity of the curves indicates the probable value of our results. The third experiment is given in order to give more accurately the upper portion of the curve. As is stated above, an acid of higher concentration was used so that the ratio of the amount of distillate to residue in the higher concentrations should not be large enough to introduce an error.

230.65	286.91	79.61	55.44	51.92	122

Discussion of Results

A study of Fig. 2 shows that starting with 10 per cent nitric acid, its concentration increased to 20 per cent when little more than half had distilled over, while from 10 to 40 per cent about three-fourths distilled over. Thus as the concentration becomes higher the rate of concentration becomes less. The data from experiment 3, Table III, lie on almost a straight line between 40 and 50 per cent. When the line is extrapolated it passes through the point of constant boiling acid as the last fraction comes over. It would appear therefore from Fig. 2 that an acid of constant boiling point could not be prepared by simple distillation. This is in accordance with what might be expected, as the concentration of the acid in the vapor is continuously below, although continuously approaching, that of the acid in the residue; the point at which this change becomes zero, of course, is at the point at which all the solution distills over.

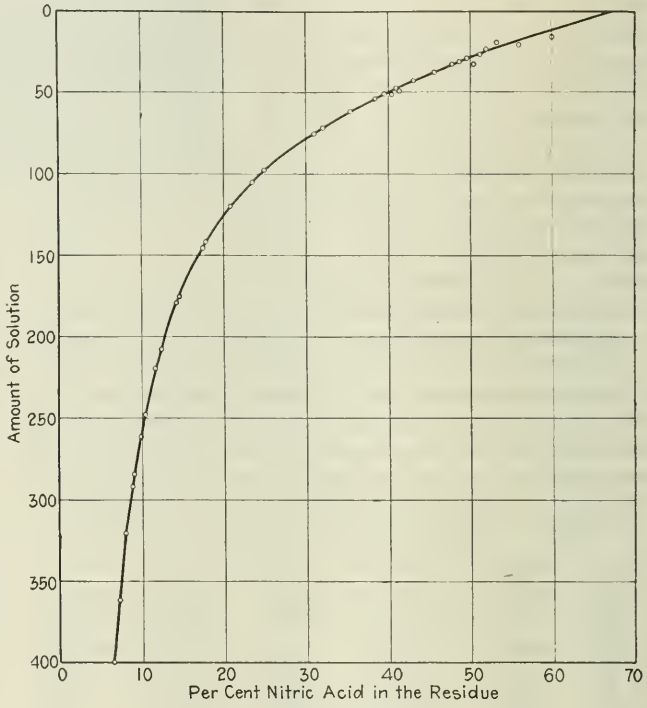

FIG. 2—CHANGE IN COMPOSITION OF NITRIC ACID RESIDUE DURING DISTILLATION

A study of Fig. 2 shows that in a distillation of 1,000 g. of a 10 per cent solution, the concentration would change as in Table IV.

TABLE IV—INTERPRETATION OF FIG. 2

Total Solution, g.	Water, g.	Acid, g.	Concentration of Residue, Per Cent HNO_3	Loss of Acid, Per Cent of Total
1000	900	100	10	0
484	387	97	20	3
302.3	212	90.7	30	9.3
197.7	118.6	79.1	40	20.9
108.6	54.3	54.3	50	45.7

Summary

1. Experimental data are given to show how nitric acid concentrates when it is distilled at atmospheric pressure, with the vapor phase in equilibrium with the liquid phase.

2. It is evident that concentration of dilute nitric acid could not be profitably carried on above 20 to 30 per cent by such a distillation, as 3 per cent is lost as the concentration changes from 10 to 20 per cent and 9.3 per cent as the concentration changes from 10 to 30 per cent.

Relation of Shale-Oil Residue to Other Bitumens*

A Preliminary Study of the Resemblance of Some of the Physical and Chemical Properties of Heavy Shale-Oil Materials to Those of Gilsonite, Asphalt and Rosin

By C. W. BOTKIN
Research Chemist for the American Shale & Petroleum Co.

SOME of the properties of the heavy residues from representative Colorado and Utah shale oils were given in a former article.[1] These properties suggest resemblance to better known and widely used bitumens and it is therefore desirable to study the relation of this "shale-oil residue" to other bituminous materials. In the study presented in this paper special attention has been given to the products of thermal decomposition at atmospheric pressure and to the effects of the decomposition on saturation and nitrogen content. Wherever data on the different bitumens could be found in the literature they have been freely used. However, little information could be obtained on the saturation of the oils produced by destructive distillation of the other bituminous materials, and it was necessary to make a distillation of each substance studied. These distillations have been made for gilsonite, asphalt and rosin, but experimental work planned for grahamite and petroleum residues has been postponed because of difficulty in obtaining authentic samples.

The destructive distillations were made in the same way as the distillation of the "shale-oil residue."[2] The oils obtained were tested for gravity and saturation,[3] then fractionated and the boiling point, gravity and saturation of each fraction determined. The distillation of the bitumen and of the resulting oil was in each case made from Pyrex distilling flasks at atmospheric pressure without steam. The gilsonite and gilsonite oil were also analyzed for nitrogen and sulphur. The data for gilsonite and the gilsonite oil are given in Table I, for asphalt and the asphalt oil in Table II, and for rosin and the rosin oil in Table III. Fig. 1 shows the saturation curves for the oils from the "shale-oil residue," gilsonite, asphalt and rosin and for the once-run Nevada oil[4] and the once-run Utah oil No. 2.[5] Fig. 2 gives specific gravity-boiling point curves for these oils, for the once-run Utah No. 1 and for pure paraffines, and indicates the position relative to the curves of the boiling point and specific gravity of a number of olefines and cyclic hydrocarbons. Table IV is a tabulation of some of the properties of the "shale-oil residue" and the corresponding properties of gilsonite, grahamite, asphalts and petroleum residues. The values for the asphalts and petroleum residues are based largely on data given by Richardson in his "Modern Asphalt Pavement, 1910," and the values for gilsonite and grahamite on the work of William C. Day, Mabery and Richardson. Credit in most instances is given in the footnotes to the table. The data (Table IV) on the "shale-oil residue" and on the products and effects of destructive distillation are taken from a former paper.[1]

The data of Tables I, II and III show a number of interesting phenomena relative to each substance that are not directly pertinent to the objects of this investigation and will not be further mentioned. A study of the data tabulated in Table IV and of the curves in Figs. 1 and 2 will serve to indicate the chief relations of the "shale-oil residue" to the other bituminous materials.

Resemblance of Shale-Oil Residue to Gilsonite

The "shale-oil residue" more nearly resembles gilsonite than any other bitumen. These materials are very much the same in gravity, high content of unsaturates and malthenes and low content of carbenes; in percentages of nitrogen, sulphur and fixed carbon; in yields of coke, gas and "additional saturates" on destructive distillation, and in the properties of the oils obtained by decomposition. The oil from the "shale-oil residue" has a saturation of 54 per cent and the oil from the gilsonite a saturation of 55 per cent. Fig. 1 shows a similarity in the saturation of the fractions of these oils, and Fig. 2 indicates almost identical specific gravity-boiling point curves. The main points of difference are a higher content of malthenes and a higher percentage of high melting point paraffines in the "shale-oil residue." This difference in heavy paraffines is indicated by the amount

of wax which crystallized from the heavy fractions of the oil from the "shale-oil residue" and from the position of the specific gravity-boiling point curves for the heavy fractions of these oils. Mabery has shown[6] that a considerable portion of the saturates from gilsonite oil belongs to cyclic series (C_nH_{2n} and C_nH_{2n-2}) and that some of the unsaturates are olefines. The saturation and specific gravity-boiling point curves for the oils from the "shale-oil residue" and the gilsonite indicate that these oils may be composed of similar series of saturated and unsaturated compounds, the proportions of which vary in about the same way throughout the ten fractions. This close resemblance in the properties of the oils obtained by destructive distillation is additional evidence of similarity in the composition of the parent substances. From a chemical standpoint the gilsonite is such bitumen as might have been removed from some oil shales by pressure and a temperature sufficiently high to cause primary decomposition.[7]

Destructive Distillation of Asphalt

The bitumen of the asphalt examined contained 18.1 per cent of saturates and the asphalt oil contained 5.8 per cent of "additional saturates" not present in this bitumen.[8] The asphalt oil decomposes very little on distillation and the content of saturates is not increased. The percentage of saturates in the asphalt oil is lower than in the once-run shale oils, but the distribution is similar. In the light fractions the curves (Figs. 1 and 2) show a rather high content of saturates and considerable likeness in gravity, boiling point and saturation to shale oils, but in the heavy fractions as the gravity increases a difference becomes more and more evident. The gravity and boiling point of the heavier fractions do not indicate the presence of paraffines. The asphalts (Table IV) resemble the "shale-oil residue" in percentage of malthenes, but the malthenes of the asphalts are higher in saturates and sulphur and as a rule lower in nitrogen.

Peckham[9] has suggested that some of the heavy materials of California petroleum high in nitrogen consist of basic oils combined with feebly acid tars. William C. Day[10] has pointed out resemblance between these petroleums and gilsonite and has made a product called artificial gilsonite by combining, in the vapor phase, the distillation products of fish (basic oil) and pine chips (acidic plant materials). The high nitrogen content of the "shale-oil residue" and the gilsonite suggests that they may be composed of basic nitrogen constituents in unstable combination with acidic resinous materials, and that such compounds may be the source of the saturates formed on decomposition. A destructive distillation of rosin was made to determine whether this material decomposes with the formation of saturated compounds. The rosin contained (data Table III) only 0.2 per cent of saturates soluble in petroleum ether, but the rosin oil, although it was highly unsaturated (20 per cent saturates), contained 17.5 per cent of "additional saturates" not present in the rosin. The oil on distillation showed little evidence of decomposition other than the formation of water. The first eight of the 10 per cent fractions of this oil have an opposite distribution of saturates to that in the shale oils. The rosin oil exhibits the paradoxical behavior of averaging 34.5 per cent for the saturates in the ten fractions, while the composited oil of these fractions tested only 22.6 per cent of saturates. After standing for 3 months, 7.7 per cent of water had separated from the composite of these fractions. The oil then tested 31.2 per cent of saturates. On redistillation the boiling points, except for the first fraction, were practically identical with the former ones and the distribution of the saturates through the fractions was also similar, but each fraction was about 4 per cent higher in saturation than in the first distillation. The composite of the fractions from the second distillation contained 31.4 per cent of saturates when tested in the usual way, while an average of the percentages found in the individual fractions was 38.5 per cent. Strange variations of this kind have been noticed for some shale oils, but the difference between the average and that of

[6] *J. Am. Chem. Soc.*, vol. 39, pp. 2022 and 2023.

[7] Prof. R. D. George has noted minute specks closely resembling gilsonite in Colorado shales. Colorado Geological Survey, Bull. 25, p. 22.

[8] These percentages are based on the weight of the pure bitumen in the crude asphalt.

[9] *Am. J. Sci.*, III, vol. 48, p. 250.

[10] J. Frank. Inst., vol. 145, p. 476.

the analysis of the composite has not usually exceeded 1 per cent and was attributed to experimental error. Error cannot be the cause of this discrepancy in the rosin oil, but the apparent inconsistency may be connected with the water, which was a decomposition product in both distillations. Mills[11] gives bromine numbers for twenty-three fractions of rosin oil obtained by steam distillation. His results indicate a similar distribution of saturates to that of Table III, and the average bromine number for the fractions is about 26 per cent less than for the crude rosin. These data obtained by bromine absorption methods tend to substantiate the data of Table III obtained by absorption in sulphuric acid.

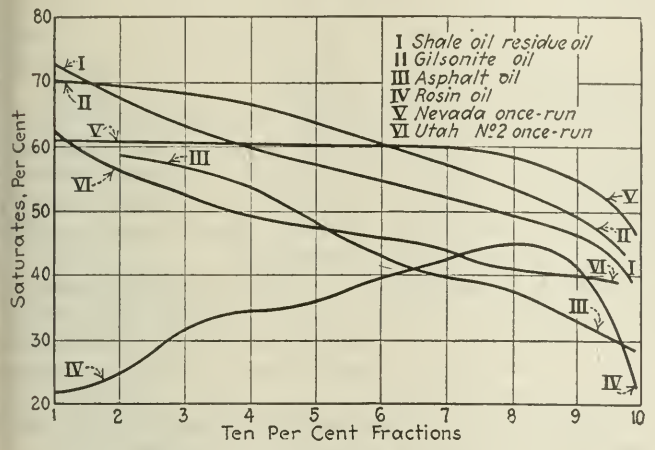

FIG. 1—SATURATION CURVES

Except in the formation of "additional saturates," the rosin bears little resemblance to the "shale-oil residue." The rosin on distillation formed small percentages of gas and coke, but a very high percentage of water. Water was also formed in both distillations of the rosin oil, but did not readily separate from the oil, and measurement was not possible except by redistillation or after standing for months in a warm place.

Petroleum residues are similar to the "shale-oil residue" in content of malthenes, but the petroleum malthenes are higher in saturates and as a rule petroleum yields less fixed carbon on distillation. Further discussion relative to these materials is at present inopportune, since no data have been obtained in regard to the amounts of gas, coke and "additional saturates" formed and nitrogen lost in destructive distillations of petroleum residues at atmospheric pressure. It has not been possible to include these distillations in the experimental work of this paper, but a study of this kind is desirable, since the results might give information regarding the truth of the hypothesis suggested by the author in a former paper[12] that "the 'additional saturates' are formed by decomposition of unstable nitrogen constituents" and might also give light on the correctness of Richardson's hypothesis[13] as to the origin of gilsonite and grahamite from petroleum. It is probable that gilsonite and the many varieties of bitumen found in and near the State of Utah may prove to be more closely related in composition to shale materials than to petroleum.

Both Richardson[14] and Mabery[15] have pointed out the differences between gilsonite and grahamite. These differences apply also to the "shale-oil residue" and grahamite. The grahamite has a higher gravity, lower content of malthenes, a much higher content of carbenes, and yields on distillation less oil[16] but more fixed carbon and residual coke than the "shale-oil residue." The large proportion of saturates noted by Mabery[16] in oil from grahamite and the small amount of saturates found by Richardson[17] in this bitumen suggest that grahamite on distillation may yield an oil of much higher saturation than gilsonite and the "shale-oil residue."

Probable Origin of Distillation Products

Mabery's statement that "while there is considerable decomposition in the initial distillation, it seems probable that heavier saturated hydrocarbons and solid paraffines form a considerable part of the natural bitumen (gilsonite) . . ."[18] is not in harmony with the very low percentages of saturates found by Richardson[19] in gilsonite and verified by the writer in the gilsonite studied in this paper. This gilsonite contained 6.6 per cent or less of saturates and the gilsonite oil contained 29 per cent of "additional saturates." There can be no doubt that large quantities of saturates are formed in the distillation of the gilsonite and the "shale-oil residue." It is probable that diminished pressure would decrease the decomposition of these bitumens on distillation and possible that grahamite may undergo a large amount of decomposition on distillation, even though the pressure is greatly reduced. Such behavior would account for the large amount of unsaturates found by Mabery in the gilsonite oil and for the rather high percentage of saturates noted by him in the grahamite oil. It is not reasonable that coal, grahamite and oil shale,

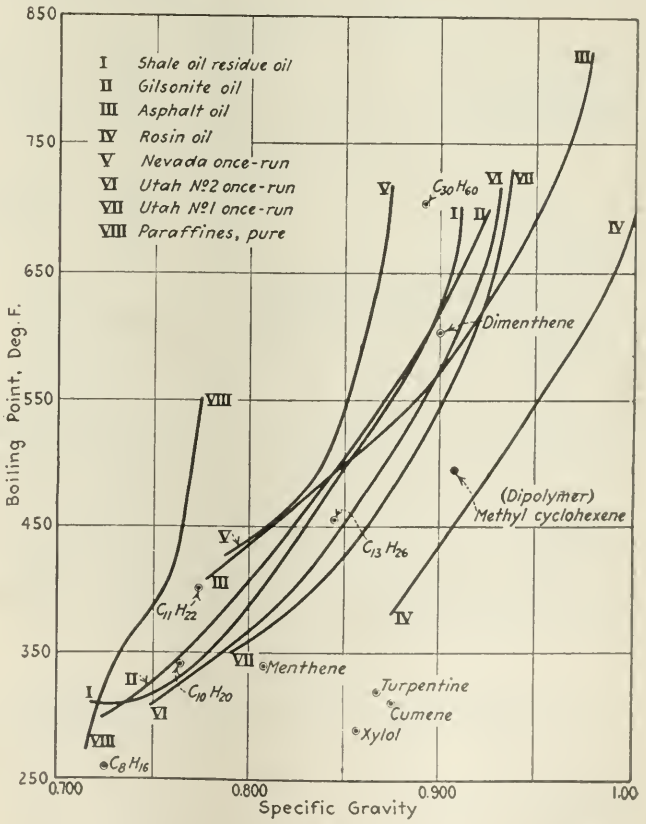

FIG. 2—SPECIFIC GRAVITY-BOILING POINT CURVES

which contain but very small amounts of materials soluble in petroleum ether, can contain paraffines in considerable quantity. The saturated and unsaturated oils produced by destructive distillation of these materials and of the gilsonite and the "shale-oil residue" must be formed by decomposition of heavy unstable materials, other than saturates, in the parent substances. It is evident from the decomposition of the crude shale oils already studied[20] that the percentage of saturated oil increases as the decomposition of the unstable material proceeds and is a maximum only when the decomposition of the unstable shale bitumen is complete.

Both the "shale-oil residue" and the gilsonite contain over 2 per cent of nitrogen. On distillation these materials lose 72.8 per cent and 76.3 per cent respectively of the original nitrogen, and the losses are attended by the formation of 23.3 per cent and 29 per cent respectively of "additional saturates." This is further evidence to that already given[21] that the unstable heavy materials, which are readily removed from the crude oils by sulphuric acid and which form "additional saturates" on decomposition, are composed largely of nitrogen compounds. On decomposition the nitrogen forms ammonia and soluble organic bases and a portion remains as a constituent of some of the lighter stable oils. Small quantities of water are noticeable in the decomposition

TABLE IV—SUMMARY OF DATA ON "SHALE-OIL RESIDUE" AND RELATED BITUMENS

	Asphalt	Petroleum Residues	Shale-Oil Residue	Gilsonite	Grahamite

products of the heavy materials of shale oils. The amount of water thus formed is very small compared with that from the rosin and it does not seem probable that the heavy shale materials can contain any very considerable proportion of oxygen. Whether in the crude shale oils the organic nitrogen bases are combined with acidic constituents such as are found in resins is a question whose solution is beyond the limits possible for the experimental work of this paper.

Summary

A preliminary study has been made of the relation of the "shale-oil residue" to other bitumens. A sample of gilsonite proved to be almost identical in properties to the "shale-oil residue" and the products obtained from these substances by destructive distillation were also similar in quantity and properties. A destructive distillation of asphalt yielded less oil and a much lower percentage of "additional saturates" than the "shale-oil residue," but the distribution of the saturates in the fractions of the oils is similar. On distillation rosin formed "additional saturates" equal in quantity to the yield from crude shale oils, but the decomposition was accompanied by the formation of a much larger quantity of water and the distribution of the saturates in the fractions of the oil was the reverse (last fraction excepted) of that in the oil from the "shale-oil residue." The shale-oil bitumen is more closely related in composition and properties to gilsonite than it is to asphalt, grahamite or petroleum residues.

The high content of nitrogen in the "shale-oil residue" and in the gilsonite, together with the large nitrogen losses which occurred when these substances were distilled, indicates that the decomposition and attending increase in saturates is probably caused by the breaking down of heavy nitrogen compounds.

The saturates in the oils from rosin, gilsonite and the "shale-oil residue" are not present as such in the parent substances, but are produced by decomposition when these substances are destructively distilled at atmospheric pressure.

The author expresses his indebtedness to R. W. Boyd for the distillation of the rosin and the rosin oil.

"Oxide Pox" Among Zinc Oxide Workers

The effects of zinc oxide dust in causing a troublesome dermatitis were observed recently in a zinc oxide manufacturing plant in the course of an investigation of the effects of inhaling zinc oxide dust. In the plant investigated the workers called the disease "oxide pox," because of its similarity to the eruption of smallpox.

Of the seventeen men examined who are exposed to the oxide dust in the bag-room and packing departments all but three gave a history of having had attacks of "oxide pox" and eight were suffering from the affection at the time of the investigation. The men had been employed for varying periods so that the length of employment did not seem to play any part in the occurrence of the disease. "Oxide pox" is caused by a clogging of the sebaceous glands with zinc oxide and subsequent bacterial infection. The disease is most prevalent in summer, although six of the men claimed they were affected regardless of the season but that it was more troublesome in the summer months. The eruption is accompanied by intense itching and usually persists for a week or 10 days, gradually subsiding and drying up, and is then followed by a slow but marked peeling of the skin. The cases studied showed no signs of systemic disturbances and no time was lost from work, although the disease caused considerable discomfort.

Zinc oxide is recognized as a non-toxic substance in which adulterating substance is so small as to be harmless, but is capable of acting as a mechanical conveyor of bacteria. It was found to be the general opinion among the workmen that the occurrence of the disease depends entirely on personal cleanliness and if daily baths are taken no trouble is experienced. Special work clothes of a close weave of cloth, made to fit snugly at neckband, wristband and ankles, should be worn to prevent the dust from coming in contact with the body.

Grain Growth and Recrystallization in Metals—III—Underlying Causes

Growth-Force of a Crystal Depends Principally Upon Small Average Grain Size and Large Contrast in Sizes—Recrystallization Is Grain Growth of Fragmented Crystals, No New Nuclei Appearing Until a New Crystalline Phase Arrives*

By Zay Jeffries and R. S. Archer
Research Bureau, Aluminum Co. of America

MATERIAL presented in previous portions of this article has consisted entirely in the presentation of the facts of grain growth and of such generalizations as may be drawn from them. It is possible that some of these statements will require correction or amendment in the light of more accurate or more complete observations, but in the main they are well established and are of immediate practical use in controlling grain growth in metals. For ready reference, the "Laws of Grain Growth" coded in the last article are here repeated.

Laws of Grain Growth

1. The grain size of cast metals is usually smaller the more rapid the rate of solidification.
2. The grain size in cast metals which undergo no phase change in the solid state cannot be changed appreciably by heating below the melting point.
3. Grain growth in the solid state may occur in (*a*) worked metals, (*b*) compressed powders, (*c*) electrodeposited metals, (*d*) in iron when it changes allotropic form and (*e*) in alloys in which a new phase is formed in the solid state.
4. The recrystallization temperature is lower (*a*) the greater the amount of deformation, (*b*) the smaller the grains prior to deformation, (*c*) the purer the metal, (*d*) the lower the temperature at which the deformation is effected and (*e*) the longer the time of heating.
5. In any given metal the grain size after complete recrystallization is normally smaller the lower the recrystallization temperature.
6. Above the recrystallization temperature the grain size is normally greater the higher the temperature and the longer the exposure.
7. The higher the temperature the more rapid the grain growth. At a temperature near the melting point a few seconds is often sufficient to produce grains which may not change further on extended exposure.
8. Certain conditions of non-uniformity sometimes give rise to the formation of abnormally large grains. This is called germination.
9. The non-uniformities giving rise to germination are: grain size contrast, strain gradients, temperature gradients, concentration gradients, and obstruction gradients.
10. The presence of foreign matter or a second phase introduces mechanical obstruction to grain growth. The resistance to growth increases as the quantity of foreign matter or other phase increases and as the particle size decreases.
11. The presence of a certain amount of obstruction matter promotes germination.
12. The higher the germination temperature the larger will be the grains and the quicker will they form.
13. The more rapid the heating through the germinative temperature range, at least within limits, the finer will be the grain size.

It is also desirable to have a conception of the fundamental causes underlying these phenomena, as by this means the various facts can be more easily correlated and new facts more rapidly discovered. Many contributions have been made to the literature on grain growth and no small part has been devoted to the theoretical aspects. Naturally many of the ideas have been discarded and certain ones have gained a sufficient following to warrant their general acceptance by metallographists. In the remainder of this article the authors will put forth a conception of the fundamental causes of grain growth consistent with the observed facts and with modern developments in molecular physics. While some of the ideas will be recognized as new, the conception as a whole is quite in accord with generally accepted theory on grain growth.

Possible Causes of Grain Growth

Grain growth obviously results from the tendency of matter to assume the form of greatest physical stability, which is the form of least energy. The crystallization of metals from the liquid state is always accompanied by an evolution of heat, representing the loss in the kinetic energy of the atoms incident to their fixation in the rigid crystal lattice. The atoms at the surface of a liquid or solid body are less subject to the attraction of their neighbors than are the atoms in the interior. They are therefore more free to move and consequently possess more energy of motion. A "free" surface of any body is thus a locus of extra energy, known as surface energy or sometimes surface tension. There is, therefore, a tendency for small particles, such as drops of a liquid or crystals of a solid, to unite to form larger particles, since in so doing they diminish their surface area and hence their total energy. It follows that the most stable form for any piece of metal would be a single crystalline grain.

To have the smallest possible surface area this grain should be spherical in shape. This would not, however, necessarily give the minimum surface energy, because of the geometrical properties of the crystal. The most stable shape for a crystalline substance is often an idiomorphic form built up of the natural crystal faces. On the other hand, it is well known that small particles of certain crystalline constituents in a metallic aggregate tend on long heating to assume a spherical form. The question is not of great importance here, and may be dismissed by saying that the most stable form of a metallic crystal is that of least surface energy, which will probably be either idiomorphic or spherical.

There has been considerable confusion in the literature on grain growth arising from a lack of distinction between true or stable equilibrium and metastable equilibrium. Some have considered that the ultimate stable condition of a piece of metal is not a single crystal, simply because such specimens are very rarely encountered and then only as a result of rather special manipulation. Such a conclusion is just as absurd as a conclusion that the gravitationally stable form of the earth's surface consists of mountains and valleys, and for the same reason. Grain growth is a process involving inertia which must be overcome just as the friction of the material composing a mountain must be overcome before the force of gravity can level it with the plain. Similarly the fact that even after prolonged annealing above the recrystallization temperature grains may be found having jagged or irregular outlines does not in any

*Part I, on Definitions, was published in Chem. & Met. Eng., vol. 26, No. 8, p. 343, Feb. 22, 1922; Part II, on Experimental Data and General Laws, vol. 26, No. 9, p. 402, March 1, 1922.

way disprove that smooth outlines would represent a condition of greater thermodynamic stability.

Obviously any roughness on the surface of a crystal is a source of increased surface energy and hence diminished stability.

If a crystal is subjected to an external load below its elastic limit, it becomes temporarily deformed or distorted. On release of the load the crystal returns to its original form. The deformation of the crystal by the external load requires an expenditure of energy which is stored in the crystal itself and manifested by its ability to return to its original shape, doing work as it returns. An elastically deformed crystal thus contains more energy than a similar crystal free from stress and distortion, and is therefore less stable thermodynamically.

We have now considered briefly all of the factors which, according to our present knowledge, may influence the stability of a crystal—namely, size, form, surface and distortion. The most stable form for a solid metal is a single crystal, spherical or idomorphic in shape, of smooth surface, and free from any distortion of its space-lattice. All solid metals must tend to assume this condition.

Conditions for Grain Growth

Any piece of metal which consists of more than one grain must possess a tendency for grain growth which is greater in proportion to the departure from the condition of maximum stability. We may for convenience designate this tendency "growth-force." Grain growth will take place whenever the growth-force is sufficient to overcome the opposition to growth. Grain growth takes place by a process of boundary migration which involves the gradual transfer of atoms from the lattice of one grain to that of the adjacent grain. Whether or not this transfer takes place through a layer of amorphous grain boundary metal, it requires a certain degree of atomic mobility of *temperature* for its accomplishment. There is usually present in metals some form of obstruction which mechanically interferes with grain growth, such as thoria in tungsten and pearlite in steel. This obstruction may be so great that it prevents grain growth altogether. In any case with a given growth-force the presence of obstructing materials raises the temperature required for grain growth.

It has been suggested that in order for one grain to absorb another it is necessary that the orientations of the two grains be very similar. Some observers have reported, however, that the relative orientation of the grains has no apparent effect on growth. It may well be imagined that although similarity of orientation might facilitate the process of growth, this very condition would also decrease the force tending to cause growth. In any event, there is not sufficient evidence to justify serious consideration of relative orientation as a factor in grain growth.

We may take as a sound foundation for the development of a theory of grain growth the proposition that the impetus of growth-force is due to a condition of thermodynamic instability and that when such a condition exists growth will take place whenever the temperature and obstruction factors permit. The factors affecting the stability of the grains of a metal and hence the growth-force have been indicated (size, shape, surface and distortion). The relative importance of these factors will now be considered more fully.

Shape and Surface of Grains

There are frequently found even in unstrained metals grains of such elongated or extended shape that the ratio of surface area to volume is abnormally high for grains of that size. Presumably such grains are less stable than grains of the same size but of more nearly equiaxed shape, which therefore tend to grow at the expense of the former. Actual observation indicates, however, that such differences in shape constitute a relatively minor factor in grain growth.

Rosenhain has observed that in deformed lead in which grain growth was occurring the outlines of the grains were ragged, while in cast lead, in which grain growth could not be produced by heating, the outlines of the grains were much more smooth. He considered that the ragged boundaries represented a condition of greater surface energy, hence less thermodynamic stability, and consequently a greater tendency for grain growth. This may account in part for the fact that grain growth occurs in worked metals but not in cast metals. General observations on the effect of grain outline or surface on grain growth phenomena are lacking, however, so that this factor cannot be incorporated as basic in a theory of grain growth.

Grain Size the Important Factor

The tendency of metals to reduce their store of energy by increasing their grain size is the factor which has probably been considered the principal cause of grain growth. There are, nevertheless, many who do not regard this as furnishing an adequate explanation of all the phenomena involved. The authors believe that grain size, considered both absolutely and relatively, is the chief factor determining the growth-force or tendency for grain growth to occur, and that it furnishes the basis for a completely satisfactory theory of grain growth.

A crystalline grain is to be regarded as an organized structure having a definite power to hold its atoms in their positions in its space-lattice, and to attract neighboring atoms into its lattice. This power is due to the cumulative effect of the directional force fields of the atoms composing the grains. The exact nature of these force fields is not known, consequently the manner of their linkage is unknown. It is held by some students of atomic and molecular physics that the attractive force of an atom does not extend to a distance of more than two or three atom diameters, in which case the orienting power of a crystal would be very little affected by its size when such a crystal contained more than about six atoms across its smallest diameter. The authors believe that the influence of the atoms within a crystal upon its orienting power extends to a much greater distance. In any event, it is certain that large crystals or crystalline grains do possess that property which has here been called "orienting power" to a greater extent than do similar crystals of smaller size.

Many examples of this general fact are known. It is known that the solubility of many salts in water is greater the finer the particles of the salt. Some figures for the solubility of calcium sulphate in water are as follows:

	Diameter of Grains	
	2 μ	0.3 μ
Solubility per liter.....	2.08 g.	2.56 g.

That is, the concentration of a saturated solution in equilibrium with an excess of the solid salt is greater the smaller the particles of the solid. This can mean only that the small particles are less capable of attracting atoms or molecules from solution than are the larger particles. The actual observed effect upon the solubility

is small, and is smaller the larger the size of the particles of excess solid. It is sufficient, however, to cause the size of the particles or crystals to increase by a process of solution and redeposition. Chemically speaking, the solution is unsaturated with respect to the smaller crystals but supersaturated with respect to the larger crystals. The former therefore dissolve and the material thus removed precipitates upon the larger crystals.

Entirely similar phenomena are observed in metals. The most familiar example is that of cementite (iron carbide) in iron. If a steel containing, say, 0.90 per cent carbon is hardened by quenching in water from about 760 deg. C. and then tempered by reheating to about 400 deg. C., it is obtained in a structural condition which is metallographically termed "troostite." Although the structure of troostite is irresolvable under the microscope, it is quite certain that it consists of submicroscopic crystalline particles of cementite imbedded in ferrite (iron). Now, if the steel is heated for several hours at a temperature of about 700 deg. C., the cementite particles become visible, and on continued heating can be observed to grow. They are not directly connected with each other in any way, so the transfer of material from one particle to another must take place through the ferrite. The smaller particles dissolve in the ferrite until a solid solution is formed which is supersaturated with respect to the larger particles. Precipitation then occurs on these larger particles, with the net result that they grow at the expense of the smaller particles. Physically this means that the larger particles have stronger attractions for their constituent atoms than do the smaller particles.

The general principle here illustrated is that in an aggregate of grains of various sizes, the larger grains tend to grow at the expense of the smaller. If we assume a condition in which all of the grains are of exactly the same size and similar in other respects, there is a balanced condition with no opportunity for grain growth, even though the tendency for growth is present, due to the fact that the thermal stability of the aggregate would be increased by an increase in grain size. The grains all possess equal powers of orientation, however, so that there is no resultant growth-force. Grain growth thus depends on a *difference* in grain size, or on what may be called grain size contrast.

While the orienting power of a crystal probably increases with its size almost indefinitely, there is ample evidence that the rate of increase is most rapid when the size is very small, and may become practically negligible for larger crystals. Thus the effect of crystal size on the solubility of salts is appreciable only for relatively small crystals. Similarly the growth of cementite particles in steel becomes very slow after they have reached a diameter of about 0.00004 in. The actual extent to which such growth proceeds is determined largely by the temperature, since a higher temperature is necessary to facilitate growth when the growth-force is small.

Meissner[1] has recently determined the effect of particle size upon the melting point of myristic acid and found that this temperature is lowered about 0.5 deg. C. by decreasing the particle size from 10 μ to 0.8 μ This phenomenon is another illustration of the fact that very small particles of solid have less attraction for their atoms or molecules than do larger particles.

The growth of certain grains in a metallic aggregate at the expense of others may be regarded as a competitive process. At the boundary between two adjacent grains there is a competition for the surface atoms, or the atoms of the essentially amorphous cement which probably surrounds the grains. The grain which has the greater orienting power attracts atoms from the other grain, and thereby grows. Drawing an analogy with vital processes, we may say that the grains have definite powers of attack and defense, and that the stronger grains feed upon the weaker. Power of attack and of defense is of course synonymous with that we have called orienting power. Orienting power depends upon grain size. The tendency for growth or the growth-force depends upon a difference in orienting power. This difference increases with the disparity in grain size and with the smallness of the smaller grain.

To sum up the above discussion, the causes favoring grain growth are:

1. Small grain size.
2. Grain size contrast.

The importance of grain size contrast as a cause of growth has been questioned by some students of the subject and has recently been emphatically denied by Carpenter and Elam[2] as a result of observations purporting to show the absorption of large grains by small ones. These observations are open to two serious objections:

1. They were made on plane sections, and grains which appear small on such a section may actually be very much larger. Given any two adjacent grains of which one is only moderately larger than the other, it will usually be possible to pass through them a plane on which the sections of the grains are reversed in size. It is therefore a mathematical probability that when the differences in grain size are not great there will be on any section including a large number of grains some cases where the larger grains appear to be the smaller. In the discussion of Carpenter and Elam's paper this objection was raised and has not been satisfactorily answered.
2. The alloy of tin and antimony used in their experiments is very soft and susceptible to strain in the polishing operation. It is therefore quite possible that an observed large grain apparently intact had actually been broken up into very much smaller fragments. There is no reason why a small unstrained grain should not absorb a large strained grain; this is in fact more probable than the reverse phenomenon.

The present authors do not know of any well-established case of the absorption of a large unstrained grain by a smaller grain. Even if some such cases should be established, however, they would merely show that some of the other factors which have been mentioned may occasionally overbalance the grain size contrast factor, and would furnish no basis whatever for the dogmatic statement that grain size contrast is not important as a cause of growth. On the other hand there is abundant positive evidence of the strongest kind that the grain size contrast principle is important and usually dominant.

Temperature and Obstruction Limiting Conditions

The presence of a growth-force due to the causes just described will not result in grain growth if the temperature is too low or if the mechanical obstruction to growth is too great. The factors are mutually interdependent. With given conditions as to mechanical obstruction, grain growth will occur at a lower temperature the greater the growth-force; or conversely, the less the growth-force the higher the temperature required to bring about grain growth. With a given growth-force the temperature required to bring about growth increases with the amount of mechanical obstruction. Thus grain growth is controlled by three factors: (1) *grain size;* relative and absolute, which determines

[1] "The Influence of State of Division on the Melting Point," Meissner, *Z. anorg. Chem.*, vol. 110, pp. 169-186, March 12, 1920.

[2] "Crystal Growth and Recrystallization in Metals," Carpenter and Elam, *J. Inst. Metals*, 1920, No. 2.

the growth-force or tendency for growth to occur; (2) *temperature,* which is equivalent to atomic mobility and determines whether the growth-force can overcome the rigidity of the metal; and (3) *obstruction,* which mechanically hinders and sometimes entirely prevents grain growth.

Metastable Equilibrium

Grain growth may fail to occur or having started may come to a halt as a result of unfavorable conditions in respect to any one of these three factors. The growth-force may be so small that even in the purest metal grain growth will not occur at any temperature short of the melting point. This is the condition that ordinarily obtains in metals solidified from the molten state and not subjected to any form of deformation. It is quite natural that this should be the case, in view of the rapidity of grain growth at temperatures near the melting point. The short time which elapses during even the most rapid solidification is sufficient for the growth-force to be reduced by the process of grain growth to such a point that no further growth will take place at lower temperatures even when maintained for long periods of time.

It is quite common to find fairly marked grain size contrast in cast metals in which it is not possible to bring about grain growth. A common example is found in ingots at the junction of the columnar grains which grew out from the mold walls with the equiaxed grains in the central portion of the ingot. Such observations have been considered by some to be inconsistent or even incompatible with the grain size contrast principle. While granting that the failure to obtain grain growth under these conditions may be influenced by the shapes of the grains or their contours, the present authors consider that the grain size principle alone is sufficient to account for the facts. While the grain size contrast may in some of these cases be considerable, the actual grain size is never very fine, in comparison to the grain size of worked metals. It is this general coarseness of grain in cast metals to which may be attributed their failure to exhibit grain growth on heating at temperatures below the melting point.

There is reason to believe that grain growth, in the solid state, does occur in cast metals during the process of solidification. An example was described earlier in this article[3] of a tungsten rod, the axial portion of which had been melted by an electric current and then allowed to resolidify. It was pointed out that whereas we might expect to find the grains formed during resolidification starting from the unmelted grains as nuclei, what we do find in fact is that the new central grains are vastly larger than the old grains in the outer rim, extending from this rim to the center of the rod. It is quite certain that in the initial stages of the resolidification the new grains actually did form upon practically all of the old grains in the rim and began to grow inward. The final result indicates very strongly that some of the larger grains absorbed their smaller and already solidified neighbors.

Upon annealing worked metals under certain conditions it has been shown that the final grain size depends very largely upon the annealing temperature. For the lower annealing temperatures the grain size depends to a large extent upon the degree of prior strain hardening, the rate of heating, time of holding at heat, etc., but at higher temperatures the effect of such variables is greatly reduced, especially if the metal is fairly free from growth obstruction, so that the annealing temperature is the principal factor determining the grain size. In other words, there is an apparent equilibrium grain size for each temperature. As the temperature of the metal is raised, grain growth takes place until the growth-force is reduced to a point where it can no longer cause growth under the existing conditions of temperature and obstruction. The metal is then in a state of metastable equilibrium as regards grain growth. In this condition the grains are usually fairly equal in size. Consequently, the normal grain growth which takes place on heating a worked metal consists merely in a change of structure toward the condition of metastable equilibrium for the temperature of the anneal.

Recrystallization Is Grain Growth

The replacement of a single strained grain by a number of unstrained grains of various orientations suggests that new crystalline nuclei are formed during the process of recrystallization. We know, however, that the strained grain has within it an abundance of nuclei in the form of fragments produced by deformation. It is more logical to suppose that recrystallization consists in the growth of some of these grain fragments to visible size than that entirely new nuclei are formed. A strained grain may be regarded as an aggregate of a large number of crystalline fragments each equivalent to a very small grain. This aggregate is not the same as an equal number of unstrained grains of similar size in annealed metal, since the boundary conditions are undoubtedly different. It is probable, too, that the change in orientation from fragment to fragment is very slight as compared with that from grain to grain in an annealed metal. In spite of such differences, the strained grain is actually an aggregate of smaller grains which, because of their small size and the size contrast unavoidably present, are especially susceptible to growth on heating.

When an annealed metal is plastically deformed, the action is most severe near the grain boundaries. The grain fragments formed are therefore smallest in these regions. Small grain size is conducive to growth at low temperatures, and it is therefore quite natural to find, on heating a strain-hardened metal under conditions of time and temperature which produce only partial recrystallization, that the new grains are first observed at the old grain boundaries. Long heating at low temperature might cause these first grains, by reason of their advantage in size, to absorb all of the grain fragments in the central portion of the old grain. In such a case the new grains could not possibly be smaller in diameter than one-half the least diameter of the strained grain. If the metal is heated quickly to a temperature well above that of incipient recrystallization, fragment growth will take place substantially at the same time in all parts of the old grain. This is probably what happens in ordinary industrial annealing.

An objection to this view that recrystallization is merely submicroscopic grain growth[4] is found in the belief held by some that during plastic deformation the grain fragments retain substantially their original orientation. It is a fact that the new grains which form from a strained grain upon proper heating have practically random orientations, all of which may differ from that of the original grain. If these new grains are held to have grown from the fragments of the old grain, then it must be considered that the fragments which acted as nuclei also possessed random orientations.

In view of the fundamental importance of the question, some experiments were made by means of X-ray analysis to determine whether or not new orientations are produced by

[3] Chem. & Met. Eng., vol. 26, No. 9, p. 403, March 1, 1922.

[4] "Recrystallization of Cold-Worked Alpha Brass on An Mathewson and Phillips, *Trans.*, A.I.M.E., vol. 54, p. 608

deformation. The methods and results have been presented fully in a recent issue of this journal[5] and will not be repeated here. The evidence was conclusive that new orientations *are* produced by the simplest types of deformation, such as rolling or pressing. A stricking illustration of change of orientation produced within a grain by twisting is shown in Fig. 1, reproduced from the same article. The definite proof that the grain fragments produced by the deformation of a single grain actually have mixed orientations removes the only valid objection to the view that recrystallizations is merely grain growth.

The actual amount of grain growth involved in the process of recrystallization is remarkably great considering the small change in temperature necessary for its accomplishment. The average grain diameter in a pure metal or solid solution alloy which has just been completely recrystallized is generally not less than about 0.0005 in. We have as yet no means of accurately measuring the fragment size in a strain-hardened metal, but we know that it is very small, since it requires only a slight deformation to produce slip bands upon a polished metal surface so close together that they cannot be resolved under the microscope. The much more severe deformations commonly effected in cold-working operations must produce fragments with diameters on the order of 0.000001 in. The increase in grain diameter during recrystallization is then about 500 to 1. In terms of grain volumes the increase is 125,000,000 to 1. The same ratio represents the decrease in the number of grains in a given volume of metal. Expressed in a slightly different way, 125,000,000 grain fragments unite during recrystallization to form one unstrained grain. The temperature change required to bring this about for ordinary periods of heating is usually not over 150 deg. C.

If a similar ratio of grain growth would be effected in the recrystallized aggregate whose grains average 0.0005 in. in diameter, the new grains would be ¼ in. in diameter. This is an enormous grain size for any normal worked metal. Such grain sizes are frequently obtained under germinative conditions as described in the second part of this article, but seldom as a result of normal grain growth, even on raising the annealing temperature from that of recrystallization to just under the melting point. This suggests that the commonly observed recrystallization normally takes place under what might be called germinative conditions.

We have seen that the recrystallization temperature is higher the less the previous strain-hardening. As a cause of grain growth, strain is merely a mechanical process of grain refinement. The greater the degree of strain the smaller are the grain fragments produced and consequently the lower the temperature at which grain growth, or recrystallization, will take place.

It is very important here and subsequently to keep clear in mind the fact that small grains or fragments facilitate growth because they are easily absorbed. In an aggregate of grains which are strained to various extents, the grains which are *least* strained are in a position to grow by feeding upon their more severely strained—i.e., fragmented—neighbors. It has been a common mistake to consider that, since strain leads to grain growth, the grains which are most strained are the ones which grow.[2] This fallacy seems to be based upon a false conception of the energetics of the case. It is held that energy is required to impart the power to grow, and that this energy must be stored in some way in the grain. The strained grain is therefore regarded as the one endowed with the power of growth. Actually the conditions are the exact reverse. The unit which does the growing is the grain of greatest thermodynamic stability and hence *least* energy content. The logic of this is apparent on considering the conditions on the solidification of a metal from the molten state. The solid, unstrained grains feed upon the molten phase, which has the higher energy content.

Grain Growth in Electrodeposits

According to the conditions of deposition, electrolytic metal may be obtained in a soft, coarse-grained variety or in a hard form whose structure is so confused that Beilby was led to the conclusion that it is amorphous. Any gradation between these two extremes may also be obtained. If the harder varieties are annealed, they are found to have "recrystallized" very much after the manner of strain-hardened metal. Beilby attributed this to the formation of crystalline nuclei in the amorphous metal. Later researches have shown that the hard electrodeposited metal is predominantly crystalline. There is little doubt that the hardness and recrystallizing properties are due to a very small grain size, just as they are in strain-hardened metal. It is sometimes said that the metal is deposited in a "state of strain," which is correct if taken to mean a condition similar to that produced by plastic deformation. The essential feature in this state of strain is the great fineness of grain.

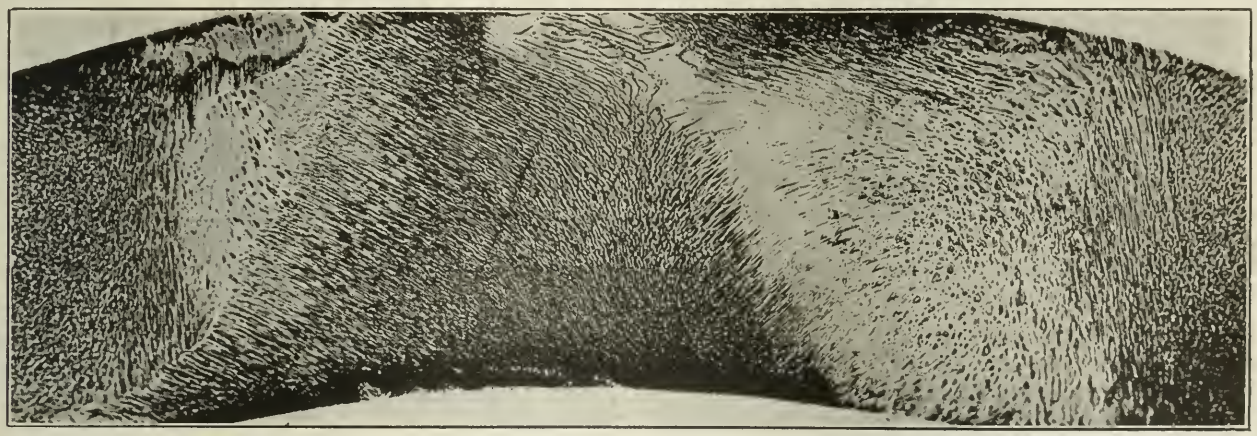

FIG. 1—SINGLE GRAIN IN TUNGSTEN WIRE, TWISTED COLD, POLISHED AND ETCHED. × 300. (TARASOV)

Metal Powders

Growth phenomena in metals formed from powders are exactly the same as in metals which have been melted and cast, although some writers would place them in a separate class. It has been erroneously stated that metal powders will not sinter to form a coherent mass when heated unless the pressure is sufficient to cause fusion at the temperature used. As a matter of fact, tungsten powder can be sintered below the melting point with no pressure except that due to its own weight. In fact it is very difficult to see how pressing a metal powder briquet could have any effect on the melting point except to raise it.

The particles of powder used in making tungsten briquets

[5] "Mixed Orientation Developed in Crystals of Ductile Metals on Plastic Deformation," Bain and Jeffries, CHEM. & MET. ENG., vol. 25, No. 17, Oct. 26, 1921, pp. 775-777.

are crystalline grains formed by reduction from tungstic oxide. It is possible that when strongly compressed some of these grains are plastically deformed. Any such strain-hardening should be removed before sintering takes place, as the sintering temperature is far above that of recrystallization. Sintering therefore consists in the union of unstrained grains accompanied by such boundary migration as is necessary, and usually by distinct grain growth. The grain size of a sintered ingot is never less than the size of the particles from which it was formed. Grain growth here is due to the usual causes—namely, grain size contrast and initial fineness of grain.

Germination

Consider the conditions of grain growth in the hypothetical case represented in Fig. 2. The small grains are supposed to be nearly alike in size, but sufficiently different to give rise to a growth-force capable of causing grain growth when the metal is heated to a suitable temperature, which we will designate *T*2. The small grains in contact with the few large grains are similar to those in the interior of the fine-grained regions. The growth-force is therefore much greater at the boundaries of the large grains than in the interior of the fine-grained regions and the large grains will grow at a lower temperature, *T*1. Now suppose the metal is heated to a temperature above *T*1 but below *T*2. The few large grains will grow at the expense of the small grains until the latter are entirely absorbed and the large grains finally meet one another. Grain growth will then cease on account of the great resistance of the large grains to absorption, and the resulting condition is represented in Fig. 3.

Suppose that instead of being heated to between *T*1 and *T*2 the metal is quickly heated to a temperature above *T*2. The large grains will then begin to absorb the small grains as before, and at an even greater rate. At the same time, however, grain growth will take place among the small grains so that presently the large grains will no longer encounter the very small, easily absorbed grains, but will meet grains of more nearly their own size, which have developed in the fine-grained regions. Grain growth may then cease, leaving the metal as shown in Fig. 4.

Conditions commonly found in metals differ only in degree from the extreme case just described. There are always some differences in growth-force from point to point in the metal, and corresponding differences in the temperature at which grain growth will begin. If the metal is heated at a temperature sufficiently high to cause grain growth at some points but not high enough to cause general growth all through the metal, conditions are favorable for the development of large grains. However, the points at which early growth begins may be so close together that the grains developed are no larger than those normal to the temperature used. On the other hand, if the centers of growth are far apart, abnormal grain growth results. It is this preferential growth of certain grains to abnormally large size which is termed germination.

All kinds of plastic deformation unavoidably produce local, if not general, strain gradients. The strain or fragmentation varies from one region of the metal to another, from grain to grain, and in different portions of the same grain. The greater the strain the lower is the temperature at which grain growth will take place on heating. Hence in a uniformly cold-worked metal it is the points of greatest strain which act as the centers of germination. The grain size produced will be larger as these centers are farther apart. This condition is favored by *slight* deformation. Severe deformation tends to make the strain or fragmentation more nearly uniform throughout the metal, and brings the points of equal strain closer together. Abnormal grain growth is therefore most commonly obtained after mild deformation.

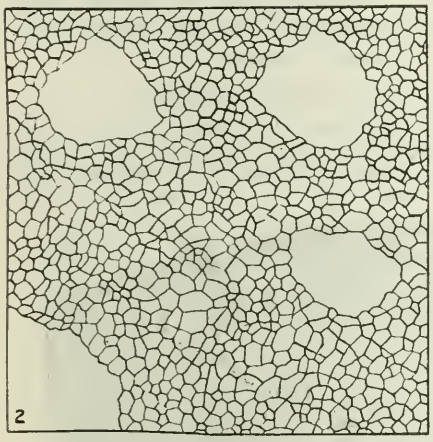

Fig. 2—Metal with moderate grain-size contrast.

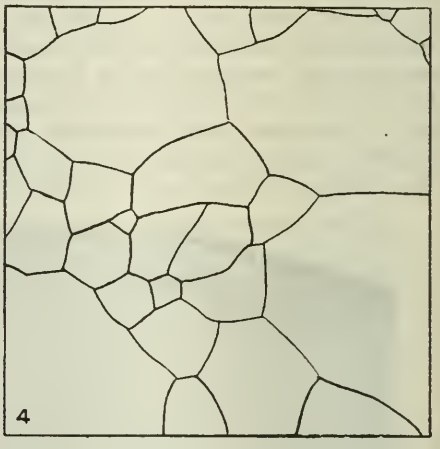

Fig. 4—Metal of Fig. 2 heated so that both sizes grow.

FIGS. 2 TO 4

Sauveur[6] found that a piece of mild steel stressed in tension to 40,000 lb. per sq.in. developed unusually large grains on annealing at 650 deg. C. If stressed to only 38,000 lb. per sq.in., this grain growth did not take place. This simply means that a stress of 40,000 lb. per sq.in. developed at a *few* points strain great enough to cause growth at 650 deg. C. in the time allowed. At 38,000 lb. per sq.in. the greatest strain produced was not sufficient to cause grain growth under these conditions. If a slightly higher temperature or a considerably longer time had been used, germination would have resulted in this case too. On increasing the stress to 42,000 lb. per sq.in. and maintaining the same conditions of annealing, grain growth occurred, but the grain size produced was comparatively fine. The centers of germination were in this case very close together.

When a metal is heated rapidly through the germinative temperature, the preferential growth of a *few* grains is prevented, because at the higher temperatures a very large number of grains are capable of growth. It might be said that they fail to attain abnormally large size because the competition is more keen.

The method of Ruder for producing excessively large grains in silicon steel and of Schaller for producing coarse-grain tungsten wire is based on a very simple type of

[6] "The Metallography and Heat-Treatment of Iron and Steel," A. Sauveur, pp. 265-271.

germination. The grain size of the starting material is sufficiently fine so that marked grain growth of the normal variety will occur at and above a suitable temperature which we will call *T*. The metal is then heated so that one region is above this temperature *T*, but the major portion is below this temperature. In the region heated above *T* grain growth will occur and there will be produced grains considerably larger than those in the colder or "inert" region, where no grain growth is taking place. (It appears that a certain amount of mechanical obstruction helps to prevent the coalescence of the small grains.) At the junction between the large grains of the growth region and the small grains of the inert region, conditions are ideal for the continued growth of the large grains at the expense of the smaller, exactly as in the hypothetical case described above in Fig. 2. The metal is now moved through the heated zone at a rate less than that at which the germinant

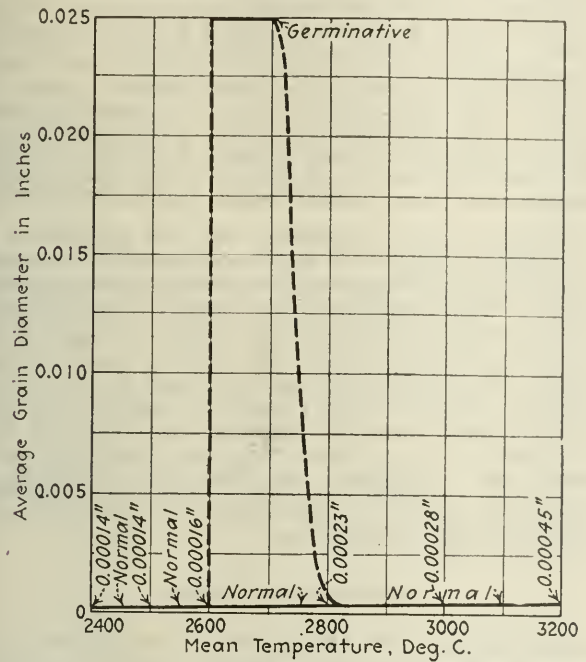

FIG. 5—GRAIN SIZE VS. TEMPERATURE FOR BRIQUETTED TUNGSTEN CONTAINING 0.75 PER CENT THORIA

grains can absorb the inert ones. Advancing the line of the growth temperature *T* at a faster rate would defeat the production of coarse grains just as does rapid heating through the germinative temperature.

The samples from which the "germinative" curve in Fig. 5[7] was obtained illustrates the effect of a temperature gradient nicely. When heated to an average temperature of 2,600 deg. C. by electric current and maintained for about 10 minutes, a few large grains formed about midway between the axis and surface of the rod. The hotter portion, near the axis, was composed of larger grains than the cooler surface portions. This shows that growth had taken place near the axis, but not at the surface. The few large grains were located at the boundary between the axial portion which may be called *growth range* and the surface portion or *inert range*. The inert grains were only inert in so far as concerns absorption by grains of their own size. Before heating, the grain size or particle size was uniform from axis to surface of the briquet. Of course there were local differences, but no general differences. A mean temperature of 2,600 deg. C. was proper to cause growth in the hotter axial portion, but not near the surface. There must then be a boundary between the growth and inert regions. The inert region is inert because of lack of grain-size contrast. Some grains in the growth range at the boundary between growth and inert regions increase sufficiently in size to absorb the inert grains and hence greatly increase in size. These grains are the "germinant" grains. The grains well within the growth range are small compared to the germinant grains, because of lack of grain-size contrast. When the germinant grains reach a size considerably larger than the grains in the growth region the latter are absorbed. The germinant grains then grow toward the surface and toward the axis, eventually producing a very coarse-grained structure as indicated in Fig. 6. The various grain sizes produced by varying the rate of heating through the germinative temperature range in these samples are in exact accord with the hypothetical case cited in Figs. 2 to 4. If the temperature is lowered a little below 2,600 deg. C., the germinant grains form nearer the axis, and with mean temperature a little above 2,600 deg. C. they form nearer the surface.

In the germinative conditions due to obstruction (Fig. 6) it was observed that the germinant grains formed first near the surface of the briquet in the 2.5 per cent thoria sample, about half way between the axis and surface in the 3 per cent thoria sample and near the axis in the 4 per cent thoria sample. The boundary between growth and inert ranges (germinative temperature) was thus at higher temperatures for the greater amounts of obstruction.

It is evident that the presence of a strain gradient in a piece of metal may lead to germination even on uniform heating. When the strain varies continuously as in Chappell's tapered bar,[8] there is some region where the degree of strain is just right to cause germination at the temperature used. After germination has taken place we have a condition similar to that described above —that is, a region of very large grains bordering on the unrecrystallized region of very small grain fragments. Grain growth will then proceed to some extent into this region, but will come to a halt when the strain decreases to a certain value. It should be especially noted that when there is a strain gradient germination may be obtained at any temperature within a rather wide range. When the strain is substantially uniform, there is only one temperature, or a narrow range of temperature, at which coarsening will take place. For this reason the chances of obtaining coarse-grained structures in industrial annealing or under high temperature service conditions is much greater when the strain is not uniform.

The important effect of the obstruction factor on germination has been pointed out. We have seen how germination in steel is most marked for a certain range of carbon content (0.04 to 0.12 per cent). In tungsten

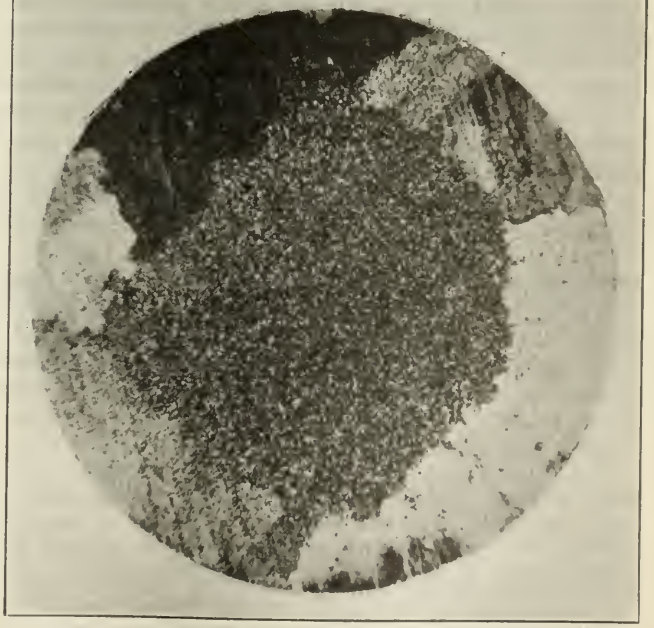

FIG. 6—GERMINANT GRAINS IN POSITION TO ABSORB SMALL GRAINS TUNGSTEN. × 25

heated under certain conditions the addition of a small amount of thoria refines the grain. More thoria causes germination, with the production of relatively enormous grains. Still more thoria inhibits growth to such an extent that no abnormally large grains are produced below the melting point. The same cycle has been shown to obtain on the solidification of a certain aluminum alloy under constant cooling conditions. The first addition of obstructing material refined the grain. A further addition caused marked coarsening, and a still further amount again refined the grain. It is not to be inferred from these examples that the progressive addition of obstruction always results in germination. Germination is in fact the exception rather than the rule. When germinative conditions *are* produced, however, the rule is that the progressive addition of obstructing material causes, first, refinement, then coarsening, then refinement. Often the first stage is not marked—that is, the first addition of obstruction may not produce a grain size noticeably smaller than in the pure metal. The germinative stage is most marked, and the return to normal grain size on the addition of more obstruction is of course equally apparent.

On analyzing the conditions under which these cases of germination occurred, we find that in Sauveur's uniformly stressed bars the coarsening resulted from local strain gradients, while in the tungsten briquets temperature gradients are responsible. In the solidifying aluminum alloy temperature and concentration gradients exist and there is unavoidably at any one time a difference in the size of the newly formed solid grains which corresponds to a strain gradient. These three cases therefore involve the principal factors which at various times cause germination. The fact that the effect of progressive additions of obstructing matter follows the same law in all cases indicates a similarity of mechanism.

Differential Growth Variety

Any case of germination in the solid state depends upon the existence at some stage of a marked grain size contrast as pictured in Fig. 2 or as described in connection with the Schaller process. This condition is always present when there are strain gradients, either general or local, since strain is equivalent to grain fragmentation. At other times, however, the grain-size contrast is not present in the original material, but is developed during the heating as the first stage of the germinative process. This is true of the Schaller process and in general of cases where germination is brought about by temperature gradients. Once this condition of grain-size contrast obtains, it is necessary, in order for germination to proceed, that the metal be held at a temperature where the rate of growth of the larger grains is very great as compared with that of the smaller grains among themselves. We may state the condition for germination as follows: *The existence of marked grain-size contrast in a metal at a temperature which permits absorption of the small grains by the larger, but not growth among the smaller grains.*

Germination thus depends upon a sharp difference in the rate of grain growth from point to point in a metal. It seems probable that the important effect of mechanical obstruction on germination is brought about through the establishment of such differences in growth velocity. We may well suppose that a given obstructing material, present in given quantity and mode of distribution, exerts its maximum obstructing effect on grain growth with respect to grains of a certain size. If such is the case, then the presence of obstruction may accentuate the differences in growth velocity already present because of varying grain size, and thereby increase the probability of germination.

Suppose an obstructing material to be present in a metal to an extent of 1 per cent by volume, and to be uniformly distributed in the form of spheres having an average diameter of 0.0001 in. Assuming for the purpose of calculation a simple cubic distribution, the shortest distance between particles is about 0.0004 in., or about four times the diameter of the particles. Now suppose the grains of the metal to be smaller in diameter than the particles. It is obvious that the particles can have no important effect on the growth of such small grains, since so few of the grain boundaries come in contact with them. If the grains are about the same size or slightly larger than the obstructing particles, the interference with grain growth will also be small in the present case, because of the distance apart of the particles. When the average grain diameter is of the same order of magnitude as the distance between obstructing particles, we may expect a rather marked hindrance to growth. Grains of very much larger size should suffer less interference because the relative distortion of their boundaries by the obstructing particles during growth by boundary migration would be less. It is therefore reasonable to assume that the obstruction to grain growth due to discrete particles scattered through a metal is greatest for a certain range of average grain diameter which is approximately equal to the average distance between particles.

According to this hypothesis, the first addition of an obstructing material to a metal would restrict the growth chiefly of the *larger* grains. Since these grains are already endowed with superior power of growth, the presence of such an amount of obstruction would *decrease* the difference in growth velocity between the larger and the smaller grains. The growth of grains of all sizes is opposed to some extent so that the general effect may well be one of grain refinement. Upon further addition of obstruction, a point will be reached where the maximum retarding effect is on those smaller grains upon which the larger germinant grains feed. Conditions are then most favorable for germination. Still further additions of obstructing material may so increase the general resistance to growth that all grains are kept relatively small.

Formation of Nuclei

It has been stated above that in the opinion of the present authors no new crystalline nuclei are formed during recrystallization. There is no evidence that such nuclei are formed except on the appearance of a new crystalline phase, which occurs in the following cases: 1. Solidification from the molten state. 2. Allotropic transformation. 3. Separation from solid solution. 4. Electrodeposition. The first two of these are most important in connection with grain growth.

Growth of the nuclei proceeds by two distinct processes. First, they feed upon the unstable disappearing phase—that is, the molten metal or the unstable allotrope (as the case may be). Secondly, if the temperature and other conditions are suitable, the larger of the new crystalline units grow at the expense of the smaller by the processes of ordinary grain growth. The resulting grain size therefore depends both upon the conditions affecting nuclei formation and upon the conditions affecting grain growth in the new phase.

Both of these factors are illustrated in the allotropic transformation of iron at A_3 (about 900 deg. C.). Suppose a piece of iron at a temperature above A_3 to be cooled very slowly from one end, so that there is a continuous temperature gradient toward the hotter end. As the cooler end passes A_3, grains of the new crystalline phase appear and grow at the expense of the adjacent disappearing high-temperature allotrope. If a sufficiently sharp temperature gradient can be maintained and advanced at a rate slower than the velocity of grain growth, the grains first formed might sweep the entire piece of metal, as in the Schaller process. Slow cooling through A_3 accompanied by temperature

gradients is therefore conducive to the formation of coarse-grained ferrite.

Slow cooling alone produces distinctly larger grains than rapid cooling. This is attributable to grain growth in the ferrite just after cooling through the A_3 temperature. The rigidity of the metal at this temperature is so great that it is possible to form completely the new phase with a grain size much smaller than the equilibrium grain size. Any exposure to temperatures immediately below A_3 therefore results in normal grain growth.

Other conditions being the same, the grain size of the new allotrope formed on heating or cooling through A_3 is roughly proportional to the grain size of the modification from which it was formed. This principle, which has been called "grain-size inheritance," is believed to depend on the fact that the nuclei of the new phase form most readily in the old grain boundaries.[9]

The fact that grain growth is seldom if ever observed on reheating single-phase cast metals is perhaps responsible for a rather general belief that there is no growth at the expense of *solid* grains during the solidification of metals. This belief leads to the conclusion that all of the crystalline nuclei formed persist, so that the number of grains in the solid metal is equal to the total number of nuclei formed during solidification. The grain size of a cast metal is then held to be a direct consequence of the laws of nuclei formation. This theory of the solidification of metals has been particularly developed by Tammann.[10]

The present authors have indicated above their opinion that normal grain growth involving the absorption of solid grains occurs during and perhaps shortly after solidification. On this basis, the number of grains left on cooling is very much less than the number of nuclei formed. There is considerable evidence that actual solidification is preceded by the formation in the liquid of groups of atoms which are essentially crystalline nuclei and yet obviously some of these groups are absorbed by others during solidification.

Germination in a solidifying alloy may be explained in very much the same way as germination in a solid metal. In the case cited, the first addition of obstructing material caused general interference with growth, but with a maximum effect on the larger potentially germinant grains. A further addition produced germinant conditions by exerting a maximum obstructing effect on the smaller grains, thereby preventing them from coalescing into large grains of greater resistance to absorption. Finally, the obstruction became so great that no grains could attain abnormally large size.

The Distortion Theory of Grain Growth

Within recent years there has been developed, largely by Czochralski,[11] an interesting theory that grain growth is caused by varying distortion of the crystal lattice. It is known that when a metal is cold-worked, internal stresses are left which must necessarily involve elastic distortion of the grains or grain fragments. It is also quite certain that the amount of relative distortion varies from grain to grain. The grains which are distorted the least are most stable and are, from the thermodynamic point of view, in a position to grow at the expense of the more severely distorted crystalline material. The distortion theory postulates that when such growth takes place, the atoms added to a grain arrange themselves in a lattice having exactly the same degree of distortion as that of the growing grain. Grain growth then involves a progressive decrease in the elastic energy of the metal due to lattice distortion. At any given temperature a state of metastable equilibrium is reached.

On heating to higher temperatures, the decreased inertia enables more growth to take place, always with a differential distortion as the cause.

This theory accounts very nicely for the absence of growth in unstrained castings, and fits in well with many of the grain growth phenomena. It depends, however, upon an assumption (which appears to the present authors so improbable as to require quite definite proof) that lattice distortion and hence internal stress exists in metals which have been fully annealed. The effect of heat upon internal stresses has been fully investigated in connection with the season cracking of brass, and it has been found that these stresses are reduced to a vanishing point by annealing *below* the temperature of recrystallization. It does not therefore seem likely that at temperatures several hundred degrees higher any appreciable distortion can exist. The surface energy due to small grains is present at all temperatures, and can be reduced only by grain growth. On the other hand, cast metals can be obtained in a condition of internal stress nearly equal to the elastic limit and involving practically the maximum possible lattice distortion in some of the grains, which distortion can be removed on heating without causing any grain growth. Such considerations lead to the conclusion that surface energy is the principal cause of grain growth.

General Propositions

1. Crystalline nuclei are formed only on the appearance of a new crystalline phase.
2. Crystalline nuclei may grow by the absorption not only of the disappearing phase but also of each other, so that the final number of grains may be less than the total number of nuclei formed.
3. Grain growth results from the tendency of metals to assume the form of greatest possible physical stability.
4. The principal conditions conducive to grain growth are small grain size and grain-size contrast.
5. Grain growth is opposed by mechanical obstruction and by inertia due to low temperature.
6. A condition of metastability as regards grain growth must be recognized, in which, while the metal is not in the most stable form, the forces tending to cause grain growth are insufficient to overcome the opposition to growth. As the temperature rises, this condition of apparent equilibrium approaches that of maximum stability.
7. Recrystallization is essentially grain growth on a submicroscopic scale.
8. Germination consists in the preferential growth of certain grains favored by their large size. The necessary condition is the existence of grain-size contrast and suitable temperature such that the larger grains can grow at a considerably more rapid rate than the smaller grains.
9. There is a critical amount of mechanical obstruction which favors the establishment of this necessary difference in growth velocity and hence germination.

Lead and Zinc Tailings May Be Used as Fertilizer

Tailings from the lead and zinc mines of southwestern Wisconsin may be used by farmers in that vicinity for fertilizer. After experiments with this byproduct at the Wisconsin University it is claimed that it may be a satisfactory source of lime for correcting soil acidity. The experiments further indicated that there are no dangers from the possible poisonous effect of the lead and zinc or the development of sulphuric acid through the oxidation of the sulphide. Quantities as large as 4 or 5 tons to the acre have been used without injurious results and with marked benefit to the clover and alfalfa. The better grade tailings, if dried and ground, would be satisfactory for shipment.

High Temperatures in Industrial Processes

Use of Various Liquids and of Superheated Steam for Transmitting the Heat Required in the Preparation and Processing of Chemicals and Allied Materials—Development of Direct-Fired Tubular Heaters for Use in the Process Industries

By PELL W. FOSTER, Jr.
Power Specialty Co., New York City

ONE of the difficult problems confronting the combustion engineer is to obtain the high temperatures often required in modern manufacturing processes in which overheating is likely to result in a loss of products. The solution of such a problem necessitates a thorough working knowledge of the many methods which may be employed as well as the ability to select from these the one which is best adapted to the peculiar characteristics of the particular process. As a matter of fact, the difficulty lies as much in the choice of the most efficient method as it does in its design or application. For example, a chemical manufacturer will commit a serious economic error if he selects, out of the several different methods which are available, one with high operating or maintenance charges. Any decision should be based on a thorough study of the relative advantages and limitations of each of the possible methods.

For the purpose of this article, high temperatures will be considered as those which are higher than can be obtained by the use of steam under moderate pressure. The methods to be considered will be limited to applications in which the delicate nature of the product precludes the use of a direct-fired kettle. By using steam at 150 lb. pressure in a closed coil or jacket, a temperature of approximately 350 deg. F. could be obtained in the product. Where temperatures higher than this are necessary in a plant having only ordinary boiler equipment and cast-iron fittings, a different sort of heating medium is required. It will be useful to consider the various methods available for this purpose, discussing in each case the characteristics which might either recommend or preclude the practicability of each for use in a particular case.

Transmission of Heat by a Liquid

The transmission of heat by a liquid consists in circulating a high-boiling liquid as a medium for conveying the heat from a direct-fired heater to the heating tank. The liquid is kept in continuous circulation by a pump between the heater and a coil placed in a tank containing the material to be heated. As the liquid travels through the tubes of the heater its temperature is raised and its total heat content is increased proportionately. Subsequently in passing through the coil or jacket of the heating tank the heat is transferred from the circulating liquid to the material being heated. Thus the liquid in the system is kept in continuous circulation and is always maintained at a higher temperature than the material to be heated.

A mineral-oil distillate of high flash point is the liquid most commonly used. The oil gives satisfactory results, as it is easy to pump, has a specific heat of about 0.5 and need not be kept under any pressure except that required to give the necessary pumping head and to exclude air. If a liquid of a lower boiling point is employed, a considerable pressure has to be carried on the system in order to keep the liquid from vaporizing. It is possible to obtain temperatures as high as 550 or 600 deg. F. by employing this method with oils now available. The limiting factor as far as high temperatures are concerned is the temperature at which the oil will crack. Overheating and possible burning of the tubes of the heater can often be attributed to the carbon deposited during the cracking or burning of the oil.

A high efficiency can be obtained by the circulation of a hot oil, due to the fact that the same oil is reheated continuously, and that no heat is lost by either rejecting the heated oil from the system or reheating make-up material. The two factors which limit the efficiency of the system are the economy developed in the oil heater and the radiation losses suffered by the oil in traveling from the heater to the heating tank. It is obvious that the oil heater should be located as close as possible to the heating tank and that the pipe lines carrying the oil to and from the tank should be well insulated. The radiation losses at fairly high temperatures in the tank are very large. Whereas it might not pay to go to the expense of lagging a tank which contains the material at 200 deg. F., it would be entirely a different matter if the temperatures were 400 deg. F. or above. Other conditions remaining constant, doubling the temperature difference between the material and the outside air will double the heat lost by radiation.

Design and Operation of Oil Heater

Having reduced the radiation losses to a minimum, the residual overall efficiency of the system depends entirely upon the design and operation of the oil heater. It should be remembered in this regard that the flue gas temperatures from the heater cannot be lower than the cool oil returned from the heating tank. Let us assume, for example, that the heater is designed along counter-current principles of flow with the coolest oil meeting the coolest gases. In this way the flue gas temperatures are reduced to the lowest possible point. But if the oil is being circulated at a high temperature with a small drop in going through the heating coil, it will necessarily follow that the gases will leave the heater at a fairly high temperature. A definite problem will serve to bring out this point. In certain acid-treating processes it is necessary to obtain temperatures of 400 deg. F. For this purpose the circulating oil passing through the heater will be raised in temperature to 475 deg. F. In passing through the heating coil and back to the heater inlet the oil loses 50 deg. F., which means that the oil at 425 deg. F. will meet the waste gases just before they are discharged. In order to make the surface at this end of the heater effective.

the gases must leave at a temperature slightly above the oil which they are to heat. For this reason the gases could probably not be cooled below 500 deg. F.

Assuming that complete combustion is being obtained in the heater, an efficiency of 70 per cent could be maintained even with the waste gases at 500 deg. F. To get the ultimate efficiency of the actual transfer of heat from the fuel to the product, deduction must be made for radiation losses. If all parts of the equipment are well insulated, this loss in the average case should not exceed 10 per cent. On this basis, therefore, a high-temperature effect could be obtained at about 63 per cent efficiency, and even in unfavorable cases this should not fall below 50 per cent.

As has already been stated, the temperature which can be developed with this method depends upon the temperature at which the oil can be circulated without danger of cracking. Even where the oil is to be circulated at temperatures which are well below those at which cracking might be expected, extreme care must be taken to avoid local overheating. Improper circulation or faulty combustion in the furnace might cause overheating and cracking of a portion of the oil in some tube section. The deposit of carbon resulting prevents transfer of heat through the tube to the oil passing on the inside, resulting in overheating and possible burnouts.

The danger of leaks in the oil heater and consequent fire hazard have been the subject of some objections to this system. However, if all joints of the heater are located outside the path of the hot gases, there is no danger of an oil leakage causing a fire and thus this danger is eliminated. Provision should also be made that a leak in a tube itself will not pour oil down into the combustion chamber.

The use of a circulating oil for heating in this way has been in very common use for the last 10 or 12 years. The close control possible has brought it into great demand in the many processes in which temperature fluctuations would be ruinous to satisfactory results. A list of products which have been treated in this way would require more space than is available in this paper, but among them might be mentioned some of the more important, such as paints, food products, acids, soaps, asphalts, vegetable oils and various chemical products.

Use of Superheated Steam

Superheated steam may be successfully employed for high-temperature heating in many different ways. All of these methods, however, may be classified under two heads according to whether the steam is actually mixed with the material to be heated or is employed indirectly in coils or jackets.

The direct use involving the injection of steam directly into the mass of the material to be heated is the more simple of the two methods and its advantages are more apparent. Fundamentally superheating steam is not only raising its temperature but is also increasing its total heat content. Just how much certain degrees of superheating add to the heat in a pound of saturated steam at 100 lb. pressure is shown in the following portion of the steam tables:

Degree of Superheat		Total Heat per lb. Above 32 deg. F. in B.t.u.	Percentage Increase in Heat Content Over Sat. Steam
Saturated	0	1,189	0
	100	1,243	5
	200	1,293	9
	300	1,342	13

It is therefore apparent that if it is desired to heat up a specified weight of liquid to a certain temperature it can be done with a smaller weight of steam by superheating. The figures given are based upon a comparison between dry saturated steam and steam with varying degrees of superheat. In actual practice the comparison is even more favorable to superheating, because the saturated steam suffers considerable heat loss, producing condensation. This appears as moisture in the steam, the amount varying with conditions such as the distance the steam must be piped to the heating tank. Superheating eliminates this moisture and thus makes an additional saving.

An idea of how superheating cuts down radiation losses may be gained from the following record of test on a long pipe line. It will be noticed that besides eliminating moisture superheating also reduces the drop in pressure.

Test Taken on 4-In. Line 500-Ft. Long, and Well Covered

Initial boiler pressure, lb.	120
Drop in pressure in line, lb.	3
Superheat at superheater, deg. F.	140
Superheat at end of line, deg. F.	90
Loss of superheat, deg. F.	50

In the heating of many substances the required temperatures cannot be obtained with saturated steam at ordinary pressures and often these pressures cannot be raised because of the condition of the boiler and steam piping. In instances where such conditions exist the steam has been superheated before being blown into the material and the necessary temperature increase obtained. The heating of vegetable oils for purposes of deodorization is an excellent example of this application. In the deodorization of these oils certain odoriferous constituents are volatilized. The temperatures at which these substances can be vaporized is in many cases above that of medium-pressure saturated steam. As steam can be superheated to a high final temperature regardless of its pressure, the oils can easily be raised to the desired point by the installation of a superheater. Also in many processes the agitation obtained by blowing superheated steam into the mixture is an important consideration.

Use in Closed Coils or Jackets

The successful use of superheated steam for heating in coils or jackets is by no means a simple problem, although in some cases it can be utilized with good economy and satisfactory results. It should be definitely noted, however, that it cannot be used in the same way as saturated steam. Often attempts are made to obtain high temperatures in a material in a kettle by merely substituting superheated steam for saturated steam in a closed coil. The results obtained are practically always disappointing.

Let us assume that we have a kettle equipped with a heating coil which has a trap on the outlet. Superheated steam is allowed to fill the coil. Before any of this steam can condense, the superheat must be given up. Consequently part of the coil is filled with saturated steam and no more superheated steam can enter until this is condensed. The temperature effect produced by this portion of the coil is therefore that of the saturated steam. The part of the coil nearest the inlet is filled with superheated steam, but even this heating surface does not afford a higher temperature. As shown in the section of the steam tables previously cited, superheating a pound of steam 100 deg. F. adds

5 per cent to the total heat content. On the other hand, it increases its volume 17 per cent.

The part of the coil filled with superheated steam therefore contains 17 per cent less steam than it would if the steam were saturated. As this superheated steam has only 5 per cent more heat per pound, it is obvious that there would be less heat units present than in the case of saturated steam. A temperature effect is after all dependent upon the transfer of the requisite number of heat units to produce the necessary increase; therefore the cutting down of the total heat content of a part of the coil will not produce any higher temperature. In addition to the fact that there are less heat units present, these heat units are given off but slowly because superheated steam parts with its heat so reluctantly. It therefore follows that superheated steam cannot usually be employed in a closed jacket or coil to obtain a higher temperature than saturated steam would have afforded.

If superheated steam is to be used to obtain high temperatures, then it must be allowed to circulate at a high rate through the coil or jacket and must leave the heating surface usually with some degree of superheat remaining in it. Thus it would be possible to heat a material up to 700 or 800 deg. F. by superheating steam to 1,000 deg. F. and allowing it to blow through a coil in a kettle. In this case, however, during the latter part of the operation the steam would have to leave the coil at temperatures above 800 deg. The practicability of this method of heating depends upon whether the heat remaining in the steam when it leaves the coil can be utilized. In some plants it has been found possible to connect up the coils of several kettles in one continuous series, staging the operation of the kettles down in temperature so that the steam can leave the last one at a fairly low temperature. The superheated steam of the highest temperature enters the high-temperature kettle and travels on to where its lower temperatures still provide a heat head. Usually this steam has no remaining superheat upon leaving the last coil and is then used in feed water heating or in some operation where the saturated steam can be condensed and the latent heat recovered.

Use With Series of Coils or a Series Superheater

The method of passing superheated steam through several coils in series gives the steam a long travel through small pipes and usually exhausts practically all the pressure in the steam. In certain cases the amount of material to be raised to a high temperature is so small that only a small coil is required. Superheated steam can be passed through such a coil with a small drop in pressure and the high-pressure saturated steam upon leaving the coil can be fed to engines or pumps. In this application the saturated steam has acted merely as a conveyor for the high-temperature effect of superheat to the process. As far as the economy of the saturated steam on the engine equipment is concerned nothing has been lost except a few pounds pressure. Moreover, if the material to be heated required a high temperature, the steam would leave the coil with considerable superheat remaining and the economy thereby produced on the engine would more than make up for the slightly lower pressure.

A series superheater has also been employed to resuperheat steam several times, alternately heating it and delivering the high-temperature heat units to a process. As this method involves using the same saturated steam to get a high-temperature effect by superheating it five or six times, only a small weight of steam is required and the economy obtained is very high.

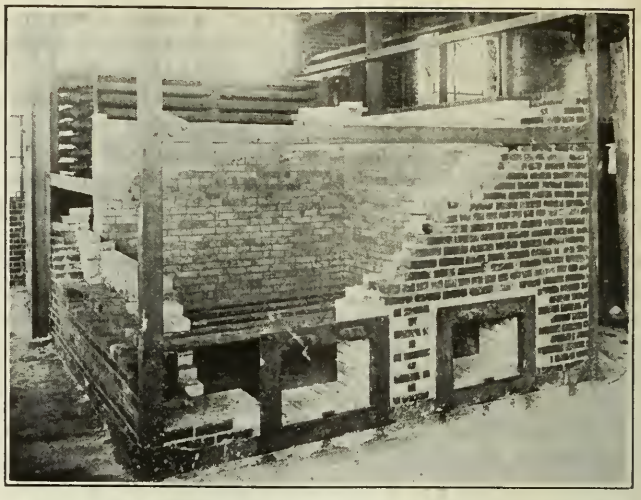

FIG. 1—DIRECT-FIRED TUBULAR HEATER FOR VEGETABLE OILS (UNDER CONSTRUCTION)

View shows armored heating surface placed behind protecting bridge wall.

In one plant where this system is employed they have been able to demonstrate an efficiency of 75 per cent. The design and installation of such a system are complicated and are usually intrusted to experts in the use of superheated steam.

Direct Heating of Materials

While it will not be attempted in this paper to discuss all the heating problems which can be solved successfully in a direct-fired kettle, it still seems worth while to point out what can be accomplished in obtaining high-temperature effects in a delicate material by means of a heater of tubular construction. At present many materials are being heated in this way which could not be handled with uniformly good results in an ordinary kettle or cylindrical still.

The obvious objection to the kettle or cylindrical form of heater is the difficulty of heating a material with any degree of uniformity. In these vessels only a small part of the material is in contact with the heating surface at the bottom where the vessel is exposed to the furnace. The result is that this material becomes very much overheated while the greater mass in the cooler parts of the vessel are insufficiently heated. Even though artificial means of establishing a circulation are resorted to, the movement set up is usually poor and cannot be counted on to maintain a uniform temperature in the product. This objection is sufficient to prevent the use of this method of direct heating in the case of many processes.

Development of Special Tubular Heaters

On the other hand, a properly designed tubular heater will often eliminate this disadvantage and make it possible to solve in this way many problems in which a slight overheating would be disastrous to the material being heated. If the heating surface consists of a series of pipes or tubes through which the material is pumped continuously and if the heat from the furnace is applied so as to avoid concentration at any point, the material will be heated gradually and evenly from

the time it enters the heater until it reaches the outlet. Moreover, the temperature in the material will gradually increase through the heater and can be brought to the proper maximum at the outlet by varying the rate of circulation and the firing.

Although it is admitted that a careful study of furnace construction and methods of applying heat generated in a furnace to a tubular heating surface should give uniform heating, the successful development of such a heater has presented many problems. Complete combustion is usually accompanied by high temperatures in the combustion chamber. The radiant heat thus evolved has a constant tendency to overheat the tubular heating surface unless some steps are taken to protect the tubes from this powerful source of heat. The first heaters of this type were built with the tubes located directly above or in the rear of the combustion chamber. With this design, however, the destructive effect of radiant heat in many cases led to frequent burning out of the hottest tubes. In other words, the radiant heat would be poured into these tubes faster than the heat-absorbing material circulating in the inside could absorb it. As radiant heat always travels in straight lines, the next step in the development of these heaters was to screen the tubular heating surface from the direct rays of heat. This was accomplished by placing the heating surface behind a bridge wall which separated it from the fire. The adoption of this design did much to eliminate the troublesome effect of radiant heat. Even so, when a heater of this design was fired hard, the heat from the combustion chambers would eventually become intense enough to raise the brick roof to a red heat. This incandescent brick in turn would reflect the radiant heat down on to the upper rows of heater tubes and would, under severe conditions, still cause local overheating and tube failures. The final step in the development of these heaters was the installation of heating surface of special construction opposite and above the main section of heating surface. Such a heater is shown in Fig. 2. The front part of the tubes directly over the furnace is screened from radiant heat by special tile. The rear part of the tubes directly over the heating surface behind the bridge wall has no tile protection, but the steel tubes are covered with a special solid cast-iron casing only a small portion of the surface of which is exposed to radiant heat. As these two opposing heating surfaces are both cooled by the liquid passing through the tube and hence are at approximately the same temperature, there can be no exchange of heat or radiation.

The tubes back of the bridge wall absorb the heat generated in the furnace almost entirely by convection and therefore at a much lower rate than by radiation. This feature tends to prevent overheating in any of the tubes and therefore makes it possible to heat the most sensitive materials without danger of spoiled products. This construction also furnishes a durable roof and improves the heater efficiency by reducing the radiation losses from the roof.

Direct Heating of Vegetable and Mineral Oils

The heating of vegetable oils for deodorization purposes is one of the difficult problems which has been solved in a tubular heater. In this process a uniform rise in temperature is essential and for many years it was believed that superheated steam offered the only satisfactory method of heating with the necessary close control. The oil must be raised to a certain temperature to obtain proper results and if any of the oil is

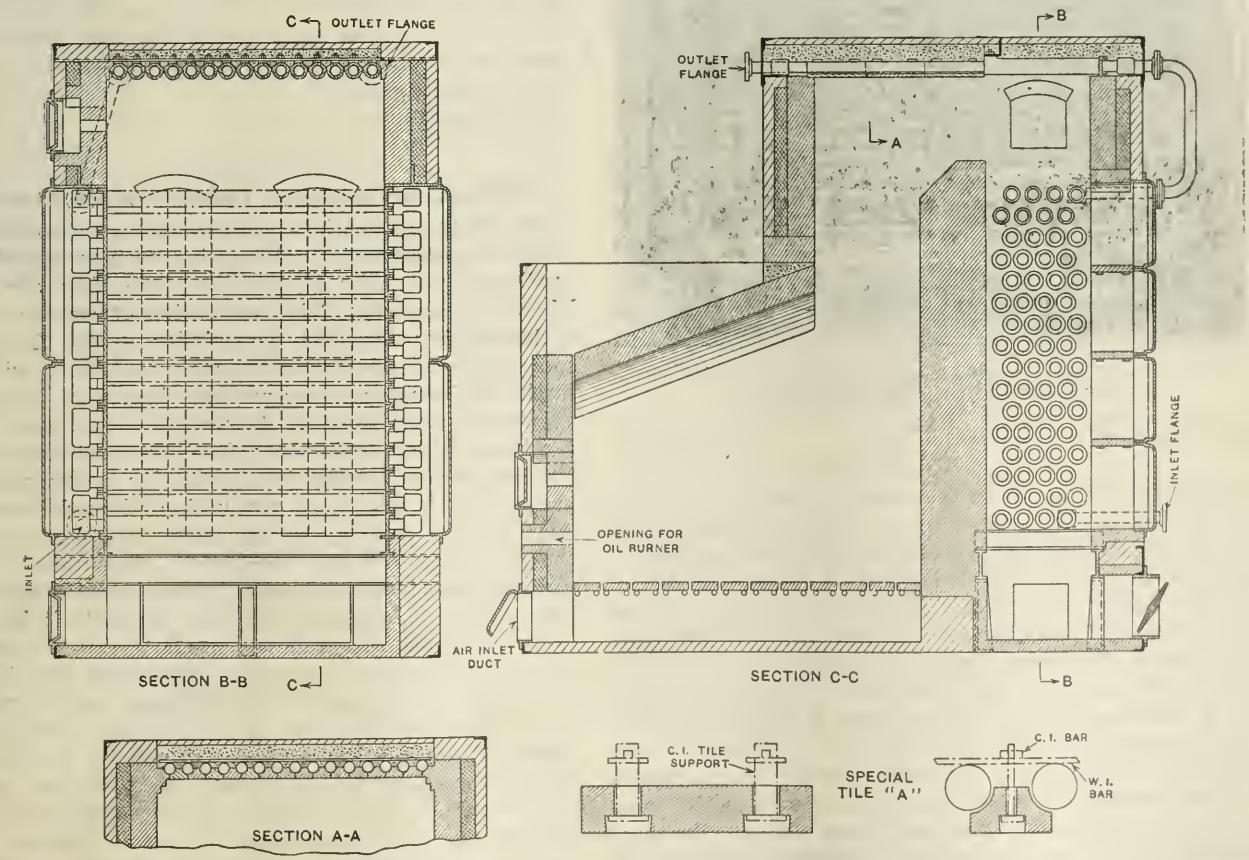

FIG. 2—SECTIONAL VIEWS SHOWING ROOF CONSTRUCTION OF SPECIAL TUBULAR HEATER FOR LIQUIDS OR GASES

unevenly heated and has a temperature below or above this predetermined limit a complete refining is not accomplished—in fact, the whole batch may be ruined. Many vegetable oil refineries are now using tubular heaters with excellent results as far as the quality of the product is concerned and greater economy than could be obtained with other methods.

As an average it may be stated that the efficiency of one of these special heaters would be about 60 per cent, although an efficiency of 67½ per cent has actually been demonstrated in some installations. The average efficiency of heating with steam in the case of vegetable oils probably does not exceed 20 per cent. The saving in time required to heat a given batch of oil through a specified temperature rise is also an important advantage. In one of these heaters it is possible to treat in 1 hour a weight of oil which would require from 2 to 4 hours in a steam still.

In the mineral oil refineries the tubular heaters have also made considerable progress in the last few years. In the cylindrical stills commonly used in refineries of this country many troubles have been encountered due to improper circulation and faulty combustion. Oil is admittedly a poor conductor of heat. As a result the oil in contact with the bottom of the tank is likely to

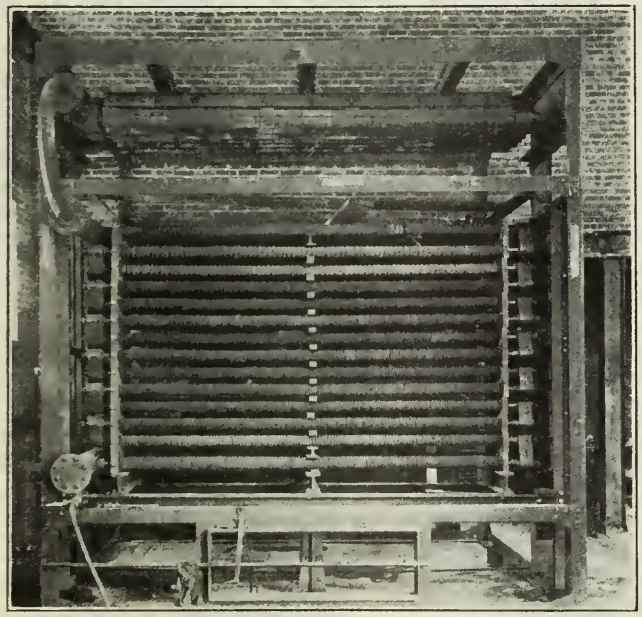

FIG. 3—SPECIAL TUBULAR HEATER FOR USE IN OIL REFINERY (UNDER CONSTRUCTION)

This view taken from rear of the heater shows special heating surface designed to absorb radiant heat.

"crack," while the oil in the cooler portions of the still fails to reach the temperature at which the desired cut can be made. The percentage of the total surface of the cylindrical still which is exposed to the furnace or the hot gases is comparatively small. The result is that this section of the plate is very much overworked and the plates oftentimes become insulated on the inside with carbon deposit and burn out. This overworking of a small portion of the surface is eliminated in a tubular heater, where every part of every tube is actually absorbing heat. Not only is more space exposed to the products of combustion but also a better heat transfer is obtained per unit area due to the high velocity of the oil in positive circulation through the tubes. This improved transfer obtained through the metal wall acts to prevent local overheating such as is encountered in the bottom plates of a tank still.

Almost any liquid which can be pumped can be handled in a tubular heater in this way. Besides mineral and vegetable oils, several heaters are now operating in roofing plants heating up the asphalt coating. Many gases have also been successfully heated to a high temperature in heaters of this same general type. In one case a highly flammable gas is being heated to a temperature above 1,000 deg. F. under a pressure of 1,500 lb. per sq.in. In all high-temperature heating problems it is well worth while to ascertain whether the material under consideration cannot be treated directly. From a consideration of the many materials handled in this way it is evident that in many cases direct heating can be utilized with much better economy than is possible with any indirect system.

Waste Heat

Where waste gases at fairly high temperatures are available, heat interchange apparatus enables effective use to be made of this waste heat in obtaining high temperatures in processes. Ordinarily waste gases are at too low temperatures to be of use for this purpose, but in the case of some furnaces or kilns the gases are available at temperatures of 1,000 or 1,200 deg. F. In this case they can be used with great economy, and advantage should be taken of this source of heat available with no additional fuel costs. Just as in the cement plants, waste-heat boilers are installed to utilize the gases from the kilns, so in chemical and other industrial plants hot waste gases can and are being used as the means of obtaining high temperatures in a process. In many of these industries the cost of obtaining high temperatures constitutes a large proportion of the total cost of the manufacture of a product, and it is therefore worth while for plant executives and engineers to study the efficiency of such processes with a view to reducing these costs.

Refining Midwestern Crude Oil to Be Studied

The Bureau of Mines is planning a comprehensive series of experiments to determine the practicability of producing the finer grades of lubricating oils from Western crude oils. The production of certain grades of lubricating oils, such as cylinder stocks, from mid-continent crudes is one of the most important problems in the oil industry at the present time.

Until recently these special products have been manufactured almost exclusively from Pennsylvania crude, but due to the increase in demand for products of this nature and to decreased production of crude from the Appalachian district, it has been necessary to seek other sources for the production of cylinder stocks. Cylinder stocks are now made from mid-continent crude, but in order to make satisfactory products it is necessary to subject the crude to special treatment for the removal of asphalt and other undesirable constituents. It is planned to make use of the experimental refinery at the Bartlesville station of the Bureau of Mines as a means of determining the best methods for handling the different types of mid-continent crudes for the production of cylinder stocks, also to determine the most satisfactory operating conditions for manufacturing products that can compete with lubricating oils made from Pennsylvania crude.

The German and American Synthetic-Ammonia Plants*—V

Costs of Construction and of Ammonia Production in the Plants at Oppau, Germany, and Sheffield, Ala., Are Compared and the Synthetic-Ammonia Problem Is Considered From the Viewpoints of the Chemist, Engineer, Operator and Executive

By R. S. TOUR

THE entire construction cost chargeable to the Oppau plant will total perhaps 250,000,000 marks. If the original pilot plant, the coke plant, the ammonia-utilization plants—i.e., ammonium sulphate, and nitric acid—be neglected and corresponding reductions made in the general facilities investment, the cost chargeable to the manufacture of ammonia alone is about one-half the entire cost, or some 125,000,000 marks. Of this about one-third is chargeable to buildings and construction, and two-thirds to equipment and machinery. The former includes buildings, foundations, roads, trackage, and all general construction; the latter covers special equipment or machinery and includes its installation cost. This is an estimate of actual pre-war (1914) cost and would mean an investment of about $270 per annual short ton of ammonia capacity, or $100,000 per daily ton. This cost applied only for the conditions existing in Germany at the time considered. In 1916, the construction costs at Merseburg showed an increase of more than 50 per cent over the Oppau figure in view of the rising labor and material charge. The 1918 estimate, based on the construction costs for the last one-fourth capacity of the Merseburg plant, had increased 150 per cent over the 1914 figure. (1914—$270; 1916—$400; 1918—$700.)

It is difficult to arrive at the labor necessary for operation. During the war there were at Oppau more than 6,000 workmen, not counting prisoners of war. This number was reduced after the war to about 5,000, directed by about 50 engineers through many superintendents and foremen. These figures include all departments of ammonia utilization, as well as construction, repair and maintenance. About 3,500 men and 35 engineers are chargeable normally to the manufacture of ammonia, including repair and maintenance of the plant. Of this number about 2,500 are required directly on operation. The labor charge of 2,500 men represents about 66 man hours per ton. The wages paid at Oppau in 1914 might average about 0.6 mark per hour. By 1918, wages had gone up in about the same proportion as the construction costs above—i.e., to 1.5 marks.

Fuel and Upkeep Charges

The only raw material necessary at Oppau is fuel. Estimates based upon reliable data indicate the following quantities of fuel per ton ammonia:

a. For water gas generators (Hydrogen production)	2 tons coke
b. For lean gas generators (Nitrogen production)	
c. For gas producers (Power and steam)	1 ton coal
d. For boilers (Steam and power)	2 tons lignite

The power and steam consumption is all included under (c) and (d). The power developed as such seems to be of the order of 3,000 kw.-hr. per ton of ammonia. The steam developed by gas engine exhaust or by boilers and consumed directly (not in steam engines) is perhaps 8 tons per ton of ammonia.

For the maintenance and repair charges (including materials and labor) we may assume 2 per cent per annum for buildings and construction and 8 per cent for equipment and machinery, which averages 6 per cent for the ammonia installation. For depreciation and amortization, we may allow 4 per cent for buildings and 7 per cent for equipment, which also averages 6 per cent for the installation. A charge for development and obsolescence is properly made on this type of plant and this has been allowed at 6 per cent on equipment and machinery only. As the process becomes more standardized and better developed this charge will decrease till it may be absorbed as depreciation and amortization, then taken at 10 per cent. These differentiations are delicate ones, since certain repair charges may be classed as depreciation while certain obsolesence charges may properly be classed with amortization. The total plant-upkeep charge per annum can be conservatively taken at 16 per cent of the investment for this type of installation.

	Buildings and Construction, Per Cent	Equipment and Machinery, per Cent	Average for Plant, per Cent
Maintenance and repair	2	8	6
Depreciation and amortization	4	7	6
Development and obsolescence	0	6	4
Total plant upkeep	6	21	16

In addition there are such fixed charges as interest, insurance, and taxes, which we may sum up at 9 per cent. The total for plant upkeep and fixed charges

PLANT PRODUCTION COST PER TON OF AMMONIA AT OPPAU, GERMANY, IN 1914

	Marks	Dollars
Labor Operating:		
35 engineers at 10,000 marks per annum	3.2	
66 man-hours per ton at 0.6 mark per hr	39.6	
	42.8	($10.27)
Fuel:		
2 tons coke at 20 marks	40	
1 ton coal at 15 marks	15	
2 tons lignite at 10 marks	20	
	75	($18.00)
Plant Upkeep:		
Repair and maintenance at 6 per cent	68.2	
Depreciation and amortization at 6 per cent	68.2	
Development and obsolescence at 4 per cent	45.5	
	181.9	($43.66)
General Works Expense:		
Unclassified expenses, 10 per cent of above	30	
Incidental materials, 5 per cent of above	15	
	45	($10.80)
Fixed Charges:		
Interest, insurance, taxes (at 9 per cent)	102.3	($24.55)
Total production cost per short ton of ammonia	447.0	$107.28
Total production cost per pound of ammonia	0.2235	0.05364

*For Parts I-IV see Chemical & Metallurgical Engineering, vol. 26, Nos. 6, 7, 8 and 9, pp. 245, 307, 359 and 411.

(25 per cent) represents over half the production cost of ammonia.

In the accompanying table is given an estimate for the cost of ammonia per ton as produced at Oppau in the form of aqua in 1914-1915, at the time the plant was developed. The cost in German marks for 1918, based on Merseburg experience and prices then existing, may be taken at about 2½ times the 1914 figure. The 1918 figure may be indicative of the present-day cost in Germany, although in view of the unsettled conditions and the prevailing rates of exchange any figures given for post-war conditions are to a large extent meaningless.

Construction Costs for the American Plant

The actual construction cost of the entire plant at Sheffield as built under emergency conditions was about $13,000,000. Thus included the nitric-acid and ammonium-nitrate plants, as well as the village for housing the employees. Of the total amount, about $7,000,000 is chargeable to synthetic-ammonia manufacture if all else be neglected and necessary deductions be made in general facilities. The plant was in many ways not completed and an additional $1,000,000 must be allowed for this purpose. This additional allowance does not consider the changes or improvements necessary for successful operation, but is to cover the incomplete installation of Unit No. 3 at the plant, the omission of properly equipped repair shops, and the future requirement of a laboratory and office building. The total of $8,000,000 represents costs under emergency conditions and may be reduced by 25 per cent for an estimate of normal construction costs at the close of the war. Based on the rated capacity of 10,000 tons per annum, the normal investment per annual ton of ammonia would thus be about $600, which at first sight compares favorably with the later construction costs of the German plants. However, in making any comparison, the following points must be kept in mind: (1) The rated capacity of the Sheffield plant may not have been its production capacity. (2) The investment in Germany included gas producers, gas engines, etc., which were necessary there to reduce the power charges and which in the United States are in general not necessary. For purposes of estimating costs for present-day construction in the United States, we can not allow less than $500 per annual ton of ammonia for plants of capacities comparable with that at Sheffield.

Based on a $500 investment per annual ton of ammonia, plant upkeep and fixed charges will represent a cost of about $125 per ton of product. The additional cost for labor, materials (fuel, power, steam, water) and other direct operating expenses will be of a like magnitude. No attempt is made here to develop these latter costs since they would depend upon the specific conditions existing at any particular plant. The total plant production cost, whether it be $250 or $300 per ton ammonia, of course includes no distribution, sales, or main office expense. It is evident from this superficial survey of costs that improvements of efficiencies at different steps of the process, with corresponding slight reductions in fuel, labor or power consumption, will not in any large proportion decrease the cost of the product. Any great saving must be accomplished by the use of the byproduct, carbon dioxide, from the process or by a reduction in the investment.

The only byproduct from the process is carbon dioxide, which is available to the extent of 40,000 to 45,000 cu.ft. per ton of ammonia. Its utilization requires the installation and operation of some additional process using the carbon dioxide and preferably a process using the ammonia as well. This calls to mind, first, the ammonia-soda process, turning out as final products ammonium chloride and soda ash. This combination of processes is in every way logical, but not as simple as it might appear. Interdependence of the two processes will make operation increasingly more difficult. Although the byproduct, carbon dioxide, would be of direct use in the ammonia-soda process, still lime would remain necessary for causticizing. The marketability and desirability of the ammonium chloride, as well as its preparation from the liquors, are also important factors. The complicating features just mentioned can be overcome in time should necessity require. A much less intricate, though less valuable, utilization of carbon dioxide is that for the double decomposition of gypsum in the presence of ammonia, yielding ammonium sulphate as the product and discarding the calcium carbonate. The German plants are using both of the above combinations, finding advantages in each. They have also experimented with the direct combination of ammonia and carbon dioxide for conversion to urea as the final product. The latter would be a very desirable solution of the entire problem of ammonia and carbon-dioxide utilization.

Some reduction in investment per unit production may be obtained by plants of very large capacities, but as long as these plants consist of multiple items of apparatus, each of comparatively small capacity, such reduction of investment can be only of a secondary order. Any large reduction in the investment must presuppose fundamental modifications of the process, as installed either in Germany or the United States. Such changes must be basic in character and represent definite reductions in the quantity or in the cost of equipment necessary for operation.

Concluding Remarks

The German process and combination of processes reached their present state of development with the financial aid of the government and under military pressure. As has been stated previously, a pilot plant had been built and preliminary experimentation completed by 1914, before the final construction and operation of the large Oppau plant to supply Germany's war needs. It is a question whether private capital would have of itself invested such large sums in the Oppau and Merseburg plants in normal times or without governmental aid. It is a further question as to whether post-war conditions are as favorable for private capital as were the pre-war conditions. We know, however, that since the plants have been built and operated successfully during the war to produce large quantities of ammonia, those plants must continue to operate and furnish ammonia for home consumption and export. The cost figures from those plants may mean but little, for a great part of their construction cost and development has been written off as a war charge.

The synthetic-ammonia industry in this country is at present in a status similar to that in Germany at the time the pilot plant at Oppau was being developed, although there is not here the enormous pressure and stimulus for development that the government put behind the German installation. It would be obviously unfair to compare the experimental plant at Sheffield

with anything but the original pilot plant in Germany. The main Oppau plant was the final development from the experimental stages through which any new and complex process must pass. Unless the Germans should take up actual construction in this country and make available their store of experience and knowledge, the industry in this country must develop its own industrial installation.

The Problem From Various Viewpoints

It is said that the industrial development of the direct synthetic-ammonia process is the greatest of modern chemical engineering problems. The true aspects of the problem, however, are somewhat beclouded by the difference in viewpoint of those following or aiding in its developments. The research chemist realizes quite rightly that the chemical problems involved are of the simplest nature except for the final step of catalysis of hydrogen and nitrogen to synthesize ammonia. He, therefore, feels that if he can develop an active and satisfactory catalytic material, the entire problem is in general solved and it remains but for the engineer to design and erect the plant. The designing engineer, on the other hand, feels that the development of a catalyst is a specific laboratory problem with which the research chemist is properly equipped to cope, but that the design of dependable equipment to operate at high pressures with temperatures at times approaching a red heat, and with gases or liquids sometimes corrosive on the materials of construction, is the really serious obstacle to success. He is appalled at the lack of data and precedents at hand for his work and is certain that if he succeeds all else is relatively simple and it only remains to erect and operate the plant. The operating chemical engineer to some extent appreciates both the above viewpoints, since he realizes to what extent his success depends on the success of both the chemist and the engineer, but he further feels that the determination and proper control of the many complicated and interdependent operating variables and steps of the process are in the last analysis the real basis of success. The industrial interests in control of commercial development have still another viewpoint. They appreciate only to a small extent the problem of the research chemist, the designing engineer, or the operating chemical engineer, but rightly feel that the success of the above men is for them a failure if the resulting investment, fixed charges or operating expenses make the cost of the product prohibitive.

Successful development of the synthetic-ammonia process can be attained only by a full appreciation of all the above viewpoints properly weighed against one another and by the most conscientious co-operation among the chemists, engineers, operators and executives. A new plant availing itself of the experience gained in operation at Sheffield, and of information obtained since then, should show very great improvement over the Sheffield plant, and there is no reason why the process could not finally be developed successfully in this and other countries as well as in Germany, if the demand for the product is sufficient to justify the investment.

Tax Returns of Precious Metal Companies

Companies engaged in the smelting and refining of precious metals in 1919 paid a total tax in that year of $6,615,353. The number of companies making returns was 567. Of this number 505 had net incomes totaling $26,285,275.

The Possibilities for Commercial Development of Muscle Shoals*

By Richard C. Tolman
Director, Fixed Nitrogen Research Laboratory

THE Muscle Shoals plant is designed to produce 220,000 tons of cyanamide per annum, which is later transformed into ammonium nitrate, amounting to 110,000 tons, as the final product of the plant. The raw materials which are used in the process are air, limestone, coke and a certain amount of coal for drying and heating purposes, and power, which might come either from the Wilson dam or from the steam power plant. The final product which the plant now makes is ammonium nitrate, which was to be used, mixed with TNT, in explosives.

Besides ammonium nitrate, there are several other nitrogen compounds which could be produced, first of which may be mentioned ammonium sulphate. This would necessitate setting up sulphuric acid units which were shipped from the Old Hickory plant. Another product, in the making of which we would employ phosphoric acid, would be ammonium phosphate. Another product which could be made there, by a method which we have worked out at the Fixed Nitrogen Research Laboratory, is urea. This material is manufactured at the present time in Germany and has been manufactured to some extent in this country. It is used at the present time, in the largest quantities, as a stabilizer for celluloid, and because of the size of the moving picture industry, considerable quanities of urea are used for that purpose. It is our belief that this material is being imported from Germany. We have tried to work out at our laboratory a process for this material, which we believe is somewhat similar to the process used in Germany, although we believe we have made improvements on the process used by the Germans.

Ammonium Nitrate as a Fertilizer

Then we have ammonium nitrate, which might well be made in certain quantities even during peace time, because it is used in peace time in permissible explosives and might work to some extent into fertilizer products. The main problem with ammonium nitrate as a fertilizer compound is that although it is an excellent plant food, nevertheless it is a very deliquescent substance. We have made a number of experiments in regard to the various possibilities of ammonium nitrate as a useful component of fertilizer products. We have gotten up methods for graining and oil-coating the ammonium nitrate, and it might be sold in that form. We have also experimented with a double salt of ammonium sulphate and ammonium nitrate. This double salt is less deliquescent than the ammonium nitrate, although not perhaps entirely satisfactory. Another method is to mix potassium chloride with ammonium nitrate. The two salts react together to form a mixture which is non-deliquescent, and that material contains two substances which are useful in fertilizer and which are used in fertilizer practice. Still another method is to mix ammonium nitrate and potassium sulphate together.

Use of Cyanamide in Fertilizer

Since the total capacity of this plant in the form of cyanamide, which is the cheapest form of nitrogen which it produces, would be 220,000 tons, it is not

*Abstracted from Dr. Tolman's testimony before the Military Affairs Committee of the House of Representatives in considering Henry Ford's offer for the Muscle Shoals plant.

believed that any large proportion of the product of the plant could be sold as cyanamide. The material cannot be used in mixed fertilizers, for the following reasons: If used in large amounts, it reacts with the acid phosphate to destroy its availability and it is also likely to produce dicyanodiamide, which is a substance poisonous to plant life. It can, however, be used in quantities of about 50 lb. to the ton of mixed fertilizer, but that would not absorb anywhere near the whole production.

We have made experiments which show that it can be more successfully mixed with basic phosphate, a material now produced by the Tennessee Coal & Iron Railroad Co. in Birmingham, and that it can be mixed with Thomas slag, a material which has been imported from Europe, and that it can be mixed with calcined phosphate, a new material which is not yet on the market.

Production of Organic Chemicals

Nitrogen, when fixed in the form of cyanamide, is combined directly with the carbon atom, and that leads to the possibility of the production of a variety of chemicals which could not be produced by other methods of nitrogen fixation. We believe the plant could produce quite a variety of organic chemicals.

Additions to the plant would have to be made in varying amounts to manufacture this variety of products. Some of the addditions would be relatively unimportant, such as putting in hydrating and oiling equipment for oiling the cyanamide. To put in phosphoric acid furnaces to make the ammonium phosphate would be more expensive.

One of the special chemicals that can be made with the help of nitrogen in the cyanamide form is nitroguanidine, which is a substance that the Ordnance Department is now experimenting with as a constituent of smokeless powder. Nitroguanidine can be obtained from nitrogen only in the cyanamide form. It is believed that there is a considerable possibility that nitroguanidine will be an important constituent of smokeless powder in the future. It was used by the Germans to some extent during the war. At the present time the only place on this continent where you can get the material to make nitroguanidine is the plant of the American Cyanamid Co. at Niagara Falls, Canada. If the smokeless powder used in the future should contain 50 per cent of nitroguanidine, which is perhaps an upper limit, the amount necessary to keep 100 divisions in the field per annum would be far larger than the total output possible at the Muscle Shoals plant. The reason why this material is a desirable substance for smokeless powder is because it has a high explosive force and yet explodes at a very low temperature, is a pure chemical substance, and is non-deliquescent.

A statement as to the possibilities of commercial success in the operation of the Muscle Shoals plant for the production of commercial fertilizer is a difficult matter, because it is trying to make predictions with regard to the future. However, the Fixed Nitrogen Laboratory feels that with ammonium sulphate at its present market price, in the neighborhood of $50 per ton, if the Muscle Shoals plant is to be run commercially to produce ammonium sulphate as its main product, the plant cannot be run and made to pay expenses.

If the Muscle Shoals plant be regarded as mainly producing ammonium sulphate, then with the price of ammonium sulphate at $65 a ton, the Fixed Nitrogen Research Laboratory feels that the plant can just about pay expenses and perhaps make a little profit, provided whoever runs the plant charges himself with a low enough figure for the water power which he uses and does not make his capital charges too high. The plant might about break even, with ammonium sulphate selling at $65 a ton, assuming a power cost of about three-quarters of a mill per kilowatt-hour and capital charges on a sum not larger than five or ten million dollars. These are our best guesses, because one cannot make precise predictions in a field of this kind.

As to the possibilities of the Muscle Shoals plant, if the plant be developed for a variety of materials, including ammonium nitrate, ammonium phosphate, urea and special chemicals of various kinds, under these circumstances, I think the plant can be made a commercial success, provided the man who obtains it surrounds himself with the proper chemical and scientific talent.

Research on Wood Conservation and Economy in Painting Planned

The Engineering Division of the National Research Council has projected a "paint on wood" research which is now being planned by the secretary of this division and G. H. Pegram and A. H. Sabin, members of a special committee responsible for the project. It is hoped that a committee will be organized representing the committee of the Engineering Foundation, American Institute of Architects, National Lumber Manufacturers Association, with representatives of painters, furniture manufacturers, piano and vehicle manufacturers and other principal users of paint and wood who will cooperate through the National Research Council in the investigation which will probably be done experimentally at the national Bureau of Standards and the Forest Products Laboratory.

Arrangement has been made with the two government laboratories named for contribution of their information and assistance regarding wood or wood treatment and paint and paint testing respectively. Among the objects sought are: Control of dimensional changes of wood due to absorption and loss of moisture; preservation of wood for economic reasons, including conservation of forests; economies in use of protective and finish coatings for wood and of the labor required for their application.

The research is to be put in the immediate charge of a well-trained technical man of varied experience, one who has not been connected directly with the lumber, wood-working or paint industries. Principal financial support aside from contributions made directly or indirectly by governmental bureaus, Engineering Foundation and National Research Council, is to be sought from producers and workers of wood and large users of protectives. Estimated cost is $8,000 to $12,000 a year for ten years. The Engineering Foundation or National Research Council will act as treasurer to receive and disburse funds.

New Metalliferous Solvent Reported Developed in Australia

Australia is preparing for commercial use a newly developed substance known as fibroferrite, according to advices to the Department of Commerce. It is said to possess valuable properties as a solvent. Its composition is given as follows: Ferrous sulphate, 50 per cent; oil of vitriol, 15 per cent; ferric sulphite, 10 per cent; alums and sulphur, 20 per cent; inert material, 5 per cent. The substance is said to possess properties which make it valuable in connection with the manufacture of red oxide of iron, disinfectants and dyestuffs.

Industries Offer Full Aid in Dye Investigation—Senator King Repeats Monopoly Charges

Monopoly, interlocking directorates, trusts, and similar appellations and charges constitute the basis of much of the attack made on the dye industry by Senator King. This is perhaps as conspicuous a point as has been raised during the past week in the proceedings before the Senate committee on investigation of this industry.

In contrast with the vitriolic attack upon the industry is the promise by Francis P. Garvan, of the Chemical Foundation, that the committee would be assisted in every way by presentation of any records or appearance of any person that might assist the investigators. The representatives of the chemical industries making dyes urge that no chance be lost to make the fullest possible presentation of the facts in the situation, as they state this will go far to dispel any feeling of improper relationship within the ranks of American dyestuff manufacturers.

It is charged by Mr. Garvan that the attacks made upon this industry can be traced back to an organized campaign of the German dye monopolies to block development of the domestic industry in the United States. This basis of discussion falls within the scope of the inquiry, as it is authorized to include not only a study of the domestic dye industry itself, but also the practices of dye importers.

The decision of Senator Shortridge of California to appeal to President Harding and Secretary of State Hughes to take prompt action to exercise whatever right the United States has to reparation dyes was made known informally at the close of Friday's session, after Albert M. Patterson, president of the Textile Alliance, had emphasized, in sworn testimony, the necessity of prompt action by the United States Government to prevent interruption of the supply of reparation dyes to the textile industry of the United States.

The State Department, in December last, terminated an arrangement whereby the Textile Alliance acted as agent for the department in importing reparation dyes allocated to the United States by the reparations commission, and distributed these dyes to the American textile trade. Since then, Mr. Patterson said, the reparations commission has declined to sell such dyes to private individuals and will soon cut the supply off altogether unless the United States Government will nominate some agency to continue or resume importation and distribution for the United States. Unless the government acts, therefore, Mr. Patterson said, the German dyes needed here will be furnished by the German dye cartel or trust instead of the reparations commission, at prices dictated by the German monopoly.

"I intend to call upon the President and the State Department, probably tomorrow, and urge that if the United States has a legal right to these dyes, the government proceed promptly to exercise that right," said Senator Shortridge. "I shall recommend that some government body or some agency be nominated to import and distribute those dyes in the United States, assuming, of course, we have a right to them. Personally, I am inclined to think we have."

Chemical Foundation Welcomes Investigation

Francis P. Garvan, former Alien Property Custodian, and now head of the Chemical Foundation, announced early in the hearing that "on behalf of myself and anybody connected directly, indirectly or remotely with the Chemical Foundation, I make haste to waive consideration of any kind whatsoever. We have been here trying for two years to have an investigation of this sort started, and while, of course, the thought never entered our heads, we are only too happy to place ourselves at your service without any consideration being asked or expected."

Senator King contended in substance that the average price of dyes in the American market today is much above pre-war prices and that the prices of intermediates have advanced in proportion. This advance he declared largely was due to special tariff and embargo legislation which he said had been passed for the benefit of the American dye industry.

Senator King declared that the Allied Chemical & Dye Corporation and the du Pont interests today have "practical control" of the manufacture of intermediates in this country. He attacked the Textile Alliance, declaring that "if it is not dominated by the American dye interests, it is working hand in hand with them to impose upon the textile industry extortionate and exorbitant prices."

He declared that it is economically wrong to prohibit importations either of intermediates or the finished products. If tariff protection is necessary, it should be "fair and just," he said. Propaganda for an embargo on importation of dyes has been and is being carried on, Senator King charged, by the Chemical Foundation, the Textile Alliance and the American Dyes Institute, which he described as "alleged eleemosynary institutions." The first, he alleged, controls all former German dye patents and formulas in this country; the second, he said, has controlled the distribution of reparation dyes in the United States, and the third, he charged, made it possible for American dye makers to "meet and agree as to prices, limit territory, restrict and regulate production and to prevent excess production."

King Questions Motives of American Dyes Institute

Senator King said the American Dyes Institute had no authority in its charter to carry on the activities he charged to its account, and also said the Textile Alliance has been acting outside the authority conferred upon it by its charter. The latter, he said, could be set aside in the courts, as a result. He further alleged that the Textile Alliance is under the domination of the Allied Chemical & Dye Corporation and the du Pont interests, adding that on the advisory committee of the Chemical Foundation and on the executive committee of the Textile Alliance are members of the "Allied" and of the du Pont interests. The du Ponts, he said, were the largest subscribers to the stock of the Chemical Foundation. The latter, he said, was conceived by Mr. Garvan and Joseph H. Choate, Jr.

The Chemical Foundation, said Senator King, has expended considerable money in propaganda. Mr. Garvan challenged a statement by King that the Foundation controlled the patent for manufacture in this country of synthetic indigo, informing Senator Shortridge that this patent lapsed years ago.

Condemns Seizure of German Patents

With the aid of a chart, Senator King sought to point out the connection between the office of the Alien Property Custodian and the organization of the Chemical Foundation. Francis P. Garvan, president of the Chemical Foundation, King said, was Alien Property Custodian; Joseph H. Choate, Jr., general counsel for the Foundation, was a dollar-a-year man in the office of the Alien Property Custodian; Ramsay Houget, patent attorney for the Chemical Foundation, was a dollar-a-year man in the office of the Alien Property Custodian; the trustees of the Foundation constituted the advisory sales committee of the Alien Property Custodian's office.

Senator King said that after the armistice, the Alien

Property Custodian, then A. Mitchell Palmer, sold, by authority of former President Wilson, 4,500 German patents to the Chemical Foundation for $250,000, although "I have been told that they were worth from $10,000,000 to $50,000,000."

Mr. Garvan was chief of the bureau of investigation in the office of the Alien Property Custodian when the patents were sold, it was developed, and later succeeded Palmer as Custodian.

The sale, Senator King further charged, was made to "officials who participated in the sale and this would be prima facie evidence of fraud in the case of private individuals."

Claims That Textile Alliance Is Aiding Monopoly

The Textile Alliance, Inc., he charged, is working "hand in glove with the domestic dye companies of the United States and is aiding them in maintaining a monopoly." Referring to the former control over the distribution of German reparation dyes in this country by the Alliance, Senator King declared the organization had acted far beyond the power of its New York state charter of incorporation and said the State of New York should proceed to disincorporate it. The Alliance, he claimed, is carrying on an aggressive campaign at Washington to continue as the sole importing agency of German reparation dyes.

In answer to questions from Senator Sterling of the subcommittee, Senator King denied any hostility to the American dye manufacturers, asserting he was not opposed to "fair and reasonable" tariff protection for them, and insisting he wished them to prosper. He declared his sole object was to attack the monopoly which he belives exists, and denounced all monopolies.

Harding Asks Definite Action on Dye Situation

The following letter written to Senator Frelinghuysen, of New Jersey, by President Harding was presented by Senator Frelinghuysen to the Judiciary sub-committee, of which Senator Shortridge, of California, is chairman.

Mr. Fleisch's full name is F. A. Fleisch and he is vice-president of the Textile Alliance, Inc.

> I have been going over the memorandum left with me by Mr. Fleisch of the Textile Alliance. I have also taken the matter up with Under Secretary Fletcher, and will pursue the matter further immediately upon the return of the Secretary of State. At the moment my best judgment is that we will get no effective arrangement made except through a resolution by Congress. I quite agree that we ought to get the benefit of such reparation credit as might come to us through the German export of dyes to this country, through the reparation commission, and we ought to protect our textile manufacturers against the grant of undue advantage to their competitors in the Old World. It would be easy to do this if Congress had not tied the hands of the administration in dealing with the reparation commission. I am writing to suggest that you confer with some of your associates regarding a resolution which will deal with the dye question definitely and directly.

Edgar Nathan of New York City, counsel for Kuttroff, Pickhardt & Company, Inc., importer of dyestuffs, obtained permission to make a statement in reply to what he termed as "unjust and misleading statements" made regarding his clients by representatives of the Textile Alliance, Inc. The officers and directors of his company, he said, are American citizens with a long record of honorable and satisfactory dealing with American consumers of dyes.

Mr. Nathan said his clients had dealt largely in dyes of American, English, French and Swiss manufacture as well as German dyes and that today their principal business is in American dyes. For many years they had the exclusive sales rights in the United States and Canada of the products of the Badische Anilin & Soda Fabrik of Germany, now one of the principal parts of the German dye cartel. Mr. Nathan said this company was not a member of the German cartel when first its relations with his clients began.

Practically every attack made upon the American dye and organic chemical industry can be traced back to a campaign of the German dye cartel, or monopoly, to block development of the industry here in order to regain control of the American market, Francis P. Garvan declared.

Blames German Intrigue for Situation

Mr. Garvan presented to the committee a story of German intrigue, beginning long before the war and continuing today, to expand in the United States German at the expense of American business. The German dye trust, he charged, really controls the business and property of its agents in this country.

The reparation system made it possible, Mr. Garvan explained, to supply dye consumers in this country with the 10 per cent they need.

"If we can continue to get this 10 per cent from the Germans through the reparations commission, the textile trade can be supplied reasonably," said Mr. Garvan. "But there is a danger that unless this is done, the textile trade will become impatient. The German dye cartel hopes to be in a position to supply us this 10 per cent on its own terms so that it can be used as a club upon the American textile trade and upon Congress to force us to take 100 per cent."

Defends Chemical Foundation

"Expressed in a few words, the main criticism against the Chemical Foundation seems to be that I, as Alien Property Custodian, transferred to myself or the Chemical Foundation, of which I was president, patents which some say were worth $1,000,000 for $250,000, so that by the German process of reasoning I derived a profit of $9,750,000.

"Senator King said we had no right to seize or sell this property; that it was in violation of the treaty of 1828. The United States Supreme Court decided in a case brought against me as Alien Property Custodian that the treaty applied only to German merchants actually in this country at the time war came on. We seized no property of any German citizen residing in America, except in the case of aliens interned because of activities against the United States Government."

Motives which caused the Alien Property Custodian to seize during the war German patents for the manufacture of dyes and drugs and to be certain that they were placed in American hands were summarized by Mr. Garvan thus:

1. Decision to make United States industry independent of the German dye trust so that no foreign power would control dyestuffs, key of many industries.
2. Resolve that the public health in the United States should not be dependent upon drugs the manufacture of which was controlled abroad.
3. Necessity of providing the United States with adequate chemical foundation for national defense.

When the United States became a belligerent, Mr. Garvan said, it was determined as a matter of national policy to seize and sell to American citizens German-owned property, including patents. The first sale by the Alien Property Custodian was the Bayer Company, manufacturer of aspirin, then owned by one of the six members of German dye cartel, he explained.

Garvan Tells of Sale of Patents

When it came to the question of disposing of the patents of the other five German trust members, it was recognized that to sell them at public auction would be dangerous, as they might fall into unfriendly or speculative hands. They were, accordingly, sold, with approval of the President, to the Chemical Foundation, which issues licenses for manufacture under the patents held by it and has never refused a license to any American manufacturer, he said.

The value of these patents, Mr. Garvan testified, was most uncertain, as in the first place they did not give the key to manufacture and, in fact, were worthless without expenditure of large sums of money in research work and for the establishment of a manufacturing plant. That American manufacturers were able to make use of these patents was a "great triumph" for American industry.

U. S. Chamber of Commerce Referendum Vote Shows Opposition of Business to Bonus

A referendum vote of the membership of the Chamber of Commerce of the United States commits the organization definitely in opposition to the cash bonus for ex-service men. A two-thirds majority of votes cast is necessary to commit the Chamber. In this case the vote against the bonus was 72 per cent. The vote will be placed immediately before Congress, now considering veteran legislation.

Although the Chamber had declared previously at two annual meetings against the cash bonus, the referendum ballot was sent out 6 weeks ago, with the desire on the part of the Chamber, according to Elliot H. Goodwin, a vice-president, "to be perfectly fair and to record any change in public sentiment if change there had been." Votes were cast by business organizations in 375 cities, 46 states, in the District of Columbia, Alaska and Hawaii, and by American Chambers of Commerce in Cuba and Mexico. Both classes of the National Chamber's membership, local chambers of commerce and trade associations, recorded themselves again the bonus by a more than two-thirds majority, although the vote of the trade associations was the heavier. The vote of the local bodies comprising the membership of the Chamber was even more strongly opposed.

The Chamber also committed itself in favor of a national system of reclamation through adequate federal appropriations to afford ex-service men an opportunity to cultivate the soil and of national legislation and appropriations to enable ex-service men to obtain vocational education.

General Fries Declares Continuation of C.W.S. Not Incompatible With Treaty

The treaty regarding submarines and gas adopted by the Limitation of Armament Conference does not attempt to abolish any service nor impose any limitations on research, development or proving, or even upon the accumulation of supplies of gas or any other materials of chemical warfare. The treaty simply prohibits "the use in war of asphyxiating, poisonous or other gases and all analogous liquids, materials or devices . . . ."

This is the interpretation of Brigadier General Amos A. Fries, chief of Chemical Warfare Service, in a statement regarding the effect of the action of the Conference on that branch of the Army. The statement continues:

"The good faith of the United States cannot be questioned if it continues the Chemical Warfare Service exactly as now constituted and doing exactly the same work as it is now doing. It is now, and would be then, simply a precaution against any other nation breaking its plighted word. There would seem to be less right to question the good faith of the United States for keeping its Chemical Warfare Service than to question its keeping its agreement not to use submarines improperly against merchant shipping, for the reason that submarines are constructed, maneuvered and supplied solely for the purpose of offensive action. Offensive action against merchant ships requires no different training, no different supplies or no different machinery than does the use of submarines against battleships.

"It is sometimes argued that we should keep up in research, but that it should not be done in a service called Chemical Warfare. If we attempt to camouflage preparations, we are immediately open to charges of perfidy in that we are secretly studying the use of gas while openly declaring that we do not intend to use it in war. That charge would be practically impossible to controvert. That a man is forbidden to carry a pistol does not in any way prevent his keeping one in his home and under proper regulations indulging in target practice so that he may successfully use it to keep out intruders. That is unquestionably the position of Great Britain and France, or Mr. Balfour and Minister Sarraut would not have had their statements to that effect recorded and made public as a part of the proceedings of the Conference. Proper preparedness is never a threat of aggression.

"It is submitted that the above is the patriotic and only proper interpretation of the treaty, and that no consideration should be given to any other interpretation."

Ladies Conduct Interesting Meeting of Chicago Section, A.C.S.

Each year the ladies of the Chicago Section of the American Chemical Society are given full charge of one regular monthly meeting. This year Feb. 24 was selected, and the enthusiastic attendance threatened to tax the seating accommodations at the City Club.

Miss Elizabeth Weirick, presiding, introduced the speaker of the evening, Miss Ruth O'Brien, associate professor of textile chemistry at Iowa State College. The opportunities for chemists in modern cleaning and dyeing establishments were pointed out by Miss O'Brien in an instructive and interesting manner. Through her intimate knowledge of conditions in cleaning and dyeing establishments throughout the country the speaker was able to indicate most convincingly the problems requiring scientific knowledge for their solution. Although essentially chemical in its nature, dealing as it does with animal and vegetable fibers, stains, cleaning agents, bleaching and finishing processes and dyes—this widespread industry engages very few chemists.

Miss O'Brien outlined the processes employed at the present time and showed how many of them had developed empirically. Like many other industries, the details of the processes vary from plant to plant, each operator being confident that his success lies in his own trade secrets. At the present time, however, the need for scientific counsel is beginning to be realized and real progress should result from the interest shown by the National Cleaners' and Dyers' Association. Miss O'Brien has been co-operating with this association and has just completed a short course in cleaning and dyeing at Iowa State College for members of the Iowa State Association.

The usual group meetings were also conducted by the ladies, the topics being as follows: "Standard Arts," by Miss Mary Hall of the Weyman-Bruton Co.; "Chemical Changes in Fats in Cooking," by Miss Katherine Blunt, University of Chicago; "A New Insight Into the Bromination of the Double Bond Between Carbon Atoms," by Prof. Ethel M. Terry, University of Chicago; "Chemical Analysis of Blood," by Dr. Chi Che Wang of the Michael Reese Hospital.

Industrial Developments of the Week

Rubber — The Erie Tire & Rubber Co., Sandusky, Ohio, has increased its operating schedule to a 24-hour basis for an indefinite period.

The Goodyear Tire & Rubber Co., Akron, Ohio, has increased production from 20,000 to 22,000 tires a day and will maintain this schedule for an indefinite time. About 500 men have been added to the working force.

The Seiberling Rubber Co., Portage, Ohio, is arranging for an immediate increase in manufacture from 839 tires a day to 1,265 tires, with corresponding advance in inner tube production from 1,000 to 1,500 per day.

Leather—Robert H. Foerderer, Inc., Philadelphia, Pa., has increased production 137 per cent as compared with this time last year. The number of employees at the plant is now 122 per cent greater than in March, 1921.

Oil—The Empire Refineries, Inc., is arranging for the immediate resumption of production at its plant at Gainesville, Tex. Other refineries of the company are increasing their outputs.

The Waco Refinery, East Waco, Tex., has placed its plant on a production basis of 2,000 bbl. of oil per day.

Ceramic—The Robinson Clay Products Co. has placed all of its plants in this district on a full running time basis. Orders on hand insure this operating schedule for some time to come.

Iron and Steel—The Gulf States Steel Co., Birmingham, Ala., has blown in its last blast furnace, following an extended idle period. The unit will be used for pig-iron production for the ingot mills of the company.

The Carnegie Steel Co. has blown in a blast furnace at its plant at Clairton, Pa., and plans to place three other units in service at an early date. The furnaces have all been out for more than a year.

The Hanna Furnace Co., Cleveland, Ohio, has relighted its blast furnace at Dover, Ohio, which has been out for

the past 13 months. About $600,000 has been expended for repairs and betterments. The plant will give employment to 150 men.

The Tennessee Coal, Iron & Railroad Co., Birmingham, Ala., will soon place its No. 4 furnace at Ensley, Ala., in blast, following a shut-down for some time past. The unit will be used for iron production for the open-hearth furnaces. The company is operating its tie-plate plant and car works under full production. The rail mill is increasing operations and the ingot department is now operating at about 77 per cent normal.

The Atlas Steel Co., Dunkirk, N. Y., has resumed operations at its plant, following a period of curtailment. Employment will be given to a large force of men.

The Glasgow Iron Co. has resumed operations at its seven puddling furnaces at the Universal Midland plant, Pottstown, Pa.

The Bethlehem Steel Co. has resumed operations at another open-hearth furnace at its Steelton, Pa., works, making six of nine furnaces now in service.

Cement—The Texas Portland Cement Co., Dallas, Tex., is arranging plans for capacity production at its mills early in March. The plant is running on a 24-hour basis, giving employment to about 250 men.

Coke—The Mt. Pleasant Coke Co. has resumed operations at its Beatty plant at Mount Vernon, Pa. The present capacity will be increased at an early date. The company recently fired over 300 ovens at its plant at Carpentertown, Pa.

The H. C. Frick Coke Co. is planning to increase operations at its plant in the vicinity of Mount Vernon, Pa.

Metals—The American Smelting & Refining Co. is arranging to increase the working force at its Perth Amboy, N. J., plant by more than 200 men. The company has taken a large smelting contract from the Phelps Dodge Corporation, New York, which will be handled at the Perth Amboy plant.

The Anaconda Copper Co. has resumed operations at its copper refinery at Great Falls, Mont., following a recent increase in output at the electrolytic plant. It is planned to give immediate employment to about 1,000 men, increasing shortly to 1,200 men. Normally, the smelting would give employment to 1,500 men.

The Mt. Shasta Gold Mining & Milling Co., Montague, Cal., has resumed production at its Black Hawk silver properties. Plans are under way for enlargements in the mill to increase the present capacity.

The Butte & Superior Copper Co., Butte, Mont., is planning to increase its present working force from 700 to 1,000 men. The company is now operating at the Black Rock concentrator at about 80 per cent of capacity and will bring production up to normal within the next few weeks.

Application of Muscle Shoals Power to Chemical Processes Denounced

The worst possible use to which the power at Muscle Shoals could be put, in the opinion of Colonel Hugh Cooper, would be its application to chemical processes. This was one of the main reasons which he advanced, while testifying before the Military Affairs Committee of the House of Representatives, as to why Henry Ford's offer for Muscle Shoals should not be accepted.

"It is not wise from the standpoint of public interest in the South to take out of its water-power reserves so great a horsepower for chemical purposes," he declared. "If this plan is consummated, the people in the South who are clamoring for the acceptance of this proposal soon will be crying for its abrogation.

"Twenty years ago at Niagara Falls they started to build what is now a 400,000-hp. plant. At that time they could not get a market for the power, so they took in the chemical people. Chemical interests and the water-power interest tied up and built up a great industry, all in chemistry. As a result, this water power at Niagara Falls did not get as far as Buffalo, 23 miles away. Two years ago Buffalo had to pay $10,000,000 for a steam plant, yet the city is within 23 miles of one of the greatest water powers in the world.

"Now there is a wide movement in the State of New York to alter the water-power situation at Niagara Falls. At this very moment they are passing legislation that is absolutely conclusive and compelling so that the power generated at Niagara Falls can be distributed throughout the tributary territory and no more of it go into chemistry.

"I do not want to be understood as saying that that these chemical industries at Niagara Falls are a curse to the country. They have accomplished a great good and the country would have been in bad shape during the war without all of them. There is a limit, however, to the water power which should be assigned to chemistry. The people of New York, after 20 years of experience with the chemical industries, are storming the Legislature to stop the use of power in chemistry in a territory that is buying coal for power use. Chemical industries do not use much labor. Take the Aluminum Company, for example. It has 150,000 hp. in its works at Messina. The town is no larger than it was 20 years ago. The South needs cheap, reliable energy to be distributed over a large territory. If you put the power at Muscle Shoals into chemistry, it will be like taking vertebræ out of a man—there would be nothing to which the ribs could be fastened. When these people get over their present spell, they will see the errors in their enthusiasm. I think it would be a tremendous calamity to the South if the greatest water power it has should be taken out of the field of public utility for 100 years."

J. W. Worthington, chairman of the executive committee of the Tennessee River Improvement Association, in his testimony before the committee, when called upon to explain if it would be wise to permit the No. 1 plant to be converted into an automobile factory, said in part:

"No prudent person would use the Haber process in view of what happened in Germany a few months ago when the Oppau plant blew up. It is rather singular, if that plant could be operated successfully—and admittedly it never has been—that the General Chemical Co., which designed it and which let the government have the process, refused Mr. Glasgow's proposal to take the plant for 3 years, when the United States would not charge a penny for its investment for the use of the plant if only the General Chemical Co. would agree to spend $500,000 in further development, investigation, research and operation. It stands today as a failure. At Syracuse, N. Y., byproduct hydrogen is available. The plant was located at Syracuse to be near the coke ovens. Suppose Plant No. 1 had proved to be a success. Even then it would not be operated by Mr. Ford. He would double it up with No. 2."

Joint Meeting of Middle Western A.C.S. Sections

A full program for the afternoon and evening of March 14 is planned for the joint meeting of the sections of the American Chemical Society co-operating in the publication of the *Chemical Bulletin*. The meeting is to be held at Northwestern University, Evanston, Ill., where excellent facilities are provided for all parts of the program. The afternoon general meeting will be addressed by H. E. Howe, editor of the *Journal of Industrial and Engineering Chemistry*, on "Chemistry's Publication Problem." The evening will be devoted to group meetings of the inorganic, organic, synthetic, biologic, educational and non-technical groups. Among the speakers at these group meetings will be H. I. Schlesinger of the University of Chicago, who will speak on "The Theory of the Chamber Process," J. A. Wilson of Milwaukee, on "The Analysis of Vegetable Tanning Materials," and Roger Adams, of the University of Illinois, on "Platinum Black Catalysts."

New Power Project for Pacific Coast

Application has been made to the Federal Power Commission for permission to construct the transmission line which will link the power systems of California with those of the Columbia River Valley. The application was filed by the California-Oregon Power Co., Medford, Ore. The transmission line for which license is asked is to extend from Prospect power house to Springfield, Ore., a distance of 100 miles.

American Institute of Chemical Engineers Announces Plans for Summer Meeting

The summer meeting of the American Institute of Chemical Engineers will be held at Niagara Falls, N. Y., June 19 to 22. Headquarters will be at the Clifton Hotel.

For the program of papers a symposium on acid manufacture is being arranged. This will include the manufacture and concentration of sulphuric, nitric and hydrochloric acids, as well as phosphoric acid. A number of excellent papers have already been promised for this symposium.

One day will be spent in Buffalo visiting the industries in that locality. Another day will be devoted to a lake trip to Toronto, Canada, and inspection of the chemical plants in that vicinity.

Technology of Lubricants Subject at Delaware Section, A.C.S., Meeting

An interesting address on the subject of "Why Oils Lubricate" was given by Prof. Robert E. Wilson, director of the Research Laboratory of Applied Chemistry of the Massachusetts Institute of Technology, at the Feb. 15 meeting of the Delaware Section of the American Chemical Society, at Wilmington, Del. The talk was based on the results of research work at the laboratory. Prof. Wilson pointed out the shortcomings of present specifications for lubricants and discussed the action of various lubricants in different uses.

C. F. Chandler Foundation Medal Presented to Edgar F. Smith

One of the most pleasant details attending the award of the Charles Frederick Chandler Foundation medal to Edgar F. Smith, president of the American Chemical Society, at Columbia University, March 2, was the fact that the token was presented by the man whose name and likeness it bears. In handing the medal to Dr. Smith, Dr. Chandler spoke of their long personal friendship and declared that there was no one to whom he would rather present the honorary award. He referred to the wonderful growth of Columbia University since 1864 when he became associated with it, a time when the student enrollment was 150 and the headquarters of the college were located in the deaf and dumb asylum.

In accepting the honor conferred upon him, Dr. Smith spoke reminiscently of his student days at Göttingen where he and Dr. Chandler studied under the same masters. He also mentioned the close relationship between Columbia University and the University of Pennsylvania, especially between the chemistry departments of the two institutions.

The Chandler medal is the result of a foundation established by the friends of Professor Chandler in 1908. Previous awards have been made to L. H. Baekeland, W. F. Hillebrand, W. R. Whitney and F. G. Hopkins.

Dr. Smith delivered an address on "Samuel Latham Mitchill—a Father in American Chemistry." Mitchill was the first professor of chemistry at Columbia College and the first Senator from the State of New York. It was particularly to his achievements in the field of chemistry, however, that the speaker gave attention.

Mitchill gained prominence in 1792 as the first public champion of anti-phlogiston views in America. He supported Lavoisier, whereas Priestley, who came to America in 1794, remained the protagonist for phlogiston until the day of his death. He gave a vivid picture of the controversy that raged. In 1797 Mitchill founded the *Medical Repository*, a journal originally intended to serve the medical profession but which later broadened its scope to take in the whole field of science. The *Repository* was strongly opposed to the phlogiston theory.

As a teacher, for such he was primarily, Mitchill was characterized by the extreme clarity of his methods and the breadth of his views and interests. It was his practice to introduce into his teachings all the new ideas and current developments in the state of the art. As professor of chemistry at Columbia he established a chemical museum in which were included exhibits of chemical products and minerals.

Among the earliest experiments conducted by Mitchill was his investigation of evaporation. In these experiments the first inklings of physical chemistry are discernible. It is worthy of note that the early chemists realized the importance and scope of this branch of the science but on account of the pressing needs of the country were forced to devote their energies to the practical applications.

Mitchill's mind was of a very speculative nature. His writings in 1802 still show the influence of the phlogiston theory but this later disappears. It was at this time that he published his belief that all matter consists of atoms, infinitely small, held together by balanced attractive and repellent forces. In his experiments on wood ashes he discovered the presence of potassium phosphate in the ash. As a result of these studies he conceived the conviction that potassium was combined with oxygen in potash and it is believed by some that this furnished Sir Humphry Davy with the clue that led to his isolation of metallic potassium.

Early in his career he had thought seriously of the causes of the decay of matter. His medical training no doubt added interest to his consideration of this problem. The most important result of his work was his conception of an imaginary element which would check organic decay and destroy the noxious products. He called this element septon, and believed it to be a combination of the "chlor" element of muriatic acid with oxygen. He declared that "septon is a fiend to animal life" and applauded the virtues of the oxychlorides of calcium and sodium as disinfectants. In this work, Mitchill was assuming the role of the present sanitary chemist and his work antedates the well known European "discoveries" by about 30 years.

He died in 1831, honored by more than 100 American and European scientific societies and famed for his work, not only in chemistry but in mineralogy, medicine, education and the public life of America.

Federal Board for Vocational Education to Fill Vacancy

The United States Civil Service Commission announces an open competitive examination for information assistant. Vacancies under the Federal Board for Vocational Education at $2,400 to $3,600 a year, and in positions requiring similar qualifications, at these or higher or lower salaries, will be filled from this examination, unless it is found in the interest of the service to fill any vacancy by reinstatement, transfer or promotion.

The duties of this position will consist of popularizing the activities and purposes of the Federal Board for Vocational Education through magazines, trade journals and the daily press and of winning public co-operation for the cause of vocational education and rehabilitation of persons disabled in industry or otherwise. It is desired that in addition to possessing journalistic qualifications, the appointee should have had trade and industrial connections and that he should be able to make personal appeals for co-operation by platform or otherwise to industrial, labor and agricultural organizations.

Competitors will not be required to report for examination at any place, but will be rated upon education and experience and published papers or articles prepared by them. Applications will be received on Form 2118 prior to March 28, 1922.

Government Needs Explosives Chemists

The United States Civil Service Commission announces that there are a number of vacancies in the Ordnance Department of the Army in positions of chemist qualified in the chemistry of explosives. These positions offer salaries ranging from $1,800 to $3,600 a year, depending upon the qualifications of the appointee and the duties to which assignment is made. Applicants are not assembled for written tests, but are rated upon the subjects of (1) education, training, and experience, weighted at 70 per cent, and (2) publications or thesis, to be filed with applications, weighted at 30 per cent.

Full information and application blanks may be obtained by communicating with the United States Civil Service Commission, Washington, D. C., or with the secretary of the U. S. Civil Service Board at the post office or custom house in any city.

General Sentiment of National Council Opposed to Metric System

The National Council of the U. S. Chamber of Commerce adopted a resolution rejecting the proposal for a referendum on the metric system at this time. An interesting discussion preceded the adoption of the resolution.

A point that had great influence on the gathering was made by George B. Chandler of the Connecticut Chamber of Commerce when he said: "If you will analyze the support of the affirmative on this question, you will find among all those proponents there is only one representative of industry. That is very significant. The others are representative of the theoretical."

W. C. Wilson, assistant to the president of the American Institute of Weights and Measures, made the principal antimetric argument. He read a concise statement from W. R. Ingalls, the president of the American Institute of Weights and Measures. Mr. Ingalls said that the greatest obstacle to the adoption of the metric system would be its cost to the people. In the manufacture of metals alone, the cost would be something like half a billion dollars, he said. Mr. Wilson, in his address said:

"If the metric system offers such extraordinary advantages as are claimed for it, is it reasonable to suppose that American manufacturers, who have stood in the forefront of industrial progress and who are thoroughly familiar with the metric system, are so blind to their own interest and so lacking in business intelligence that they must have it crammed down their throats by compulsory legislation?"

George B. Blow, of the Illinois Valley Manufacturers Association, who is a manufacturer himself, advocated the adoption of the metric system vigorously. "England is very much in the same condition as ourselves," he said. "She is clamoring for metric weights and measures because she has found out that the country is losing foreign business to the metric countries. England is finding out that Germany and other metric countries are getting business from them, particularly in South America. We have no right to vote down a proposition to submit anything to a referendum. This matter should go to referendum as recommended by the committee."

Charles L. Parsons, secretary of the American Chemical Society, among other things said: "I want to speak for a whole profession. The chemists of America are united in one immense society with 15,000 members. The chemists of America use the metric system daily. They are absolutely united in favor of it. I have no sympathy with the argument of cost. If we followed that argument we would be riding buggies while the rest of the world would be using automobiles."

Educational Conference on Business Training of the Engineer

The United States Commissioner of Education is calling a second public conference on commercial engineering on behalf of a committee on commercial engineering appointed by him to investigate business training of engineers and engineering training for students of business. The conference will be held May 1 and 2 at the Carnegie Institute of prominent deans of schools of engineering and of commerce and of engineers and business men who are nationally known for their interest in the reduction of the costs of production, distribution, transportation, etc.

Outstanding topics at the Pittsburgh conference will deal with the new problems that have recently arisen in modern industries, the solution of which demands a more scientific approach. This will include the training of the engineer for a better understanding of problems relating to community development and for the management of overseas engineering projects.

No Nichols Medal Award for 1921

No award of the Nichols Medal will be made this year, it is announced. The medal is awarded to the writer of the most exceptionally meritorious article appearing during the year in the journals of the American Chemical Society. The passing of the award is due to lack of articles of sufficient merit.

Personal

O. M. Butler, who was assistant director of the Forest Products Laboratory at Madison, Wis., has tendered his resignation, effective March 1. He will leave Madison for Washington, D. C., to join the American Forestry Association to direct its technical activities.

Ernest W. Dean has resigned as petroleum chemist of the Bureau of Mines, Pittsburgh, Pa., to join the staff of the Standard Oil Company of New Jersey as director of the standard inspection laboratory. Mr. Dean's successor in charge of the Pittsburgh petroleum laboratory of the Bureau of Mines is N. A. C. Smith, formerly of the Washington office.

Frank R. Eldred and Frederick C. Atkinson announce the organization of Eldred & Atkinson, Inc., chemical adviser and engineer, with offices at 48 East 41st St., New York City, and 1857 Gent Ave., Indianapolis, Ind.

Henry Harnischfeger, president of Pawling & Harnischfeger Co., Milwaukee, Wis., left on Jan. 28 on a combined business and pleasure trip around the world. He is accompanied by Mrs. Harnischfeger, and they plan to go to Japan, the Philippines, China, Burma, Ceylon, India, and up through the Suez Canal to Naples and Europe.

Pierre E. Hayes, formerly with Linde Air Products Co. and the Prest-O-Lite Co., announces the establishment of a consulting engineering office in the Ellicott Square Building, Buffalo, N. Y. His services will be available for the conduct of research, development, test or survey work involving chemistry, physical chemistry, thermodynamics or engineering economics.

David W. Jayne and Herbert G. Sidebottom, formerly associated with The Barrett Co., New York, have entered business together under the corporate name of Jayne & Sidebottom, Inc. They will act as manufacturers' agents in the sale or purchase of chemicals commonly used in the textile, paint, rubber, dye, chemical, pharmaceutical, paper, leather and allied industries. Their offices are in the Whitehall Building, 17 Battery Place, New York.

Colonel E. Lester Jones, director U. S. Coast and Geodetic Survey, Washington, D. C., spoke on March 2 at the Franklin Institute on "Surveying From the Air."

L. Charles Mazzola, assistant superintendent of the Metal & Thermit Corporation, spoke on March 3 at a meeting of the chemical society, which was held in conjunction with the mechanical society of Polytechnic Institute. His subject was "Thermit and Its Application."

Edwin J. Prindle, patent attorney, of Prindle, Wright & Small, New York, was presented by the Commissioner of Patents with the pen with which President Harding signed the Patent Office bill.

Kirby Thomas of New York has been examining the limestone deposits in Parkers Landing, Butler County, Pa.

The American Institute of Mining and Metallurgical Engineers announces the election of new officers of the Institute of Metals Division, as follows: Chairman, W. B. Price, Scovill Manufacturing Co., Waterbury, Conn.; vice-chairman, George K. Elliott, Lunkenheimer Co., Cincinnati, Ohio; secretary and treasurer, W. M. Corse, Monel Metal Products Corporation, Bayonne, N. J. The executive committee is composed of George K. Elliott, Lunkenheimer Co., Cincinnati, Ohio; C. T. Bragg, Michigan Melting & Refining Co., Detroit, Mich.; H. M. Lane, H. M. Lane Engineering Co., Detroit, Mich.; Lawrence Addicks, New York City; William Campbell, Columbia University, New York City; J. A. Capp, General Electric Co., Schenectady, N. Y.; E. E. Thum, Chem. & Met. Eng., Tenth Ave. and 36th St., New York City; George F. Comstock, Titanium Alloy Manufacturing Co., Niagara Falls, N. Y.; W. A. Cowan, National Lead Co., Brooklyn, N. Y., and H. M. Williams, General Motors Research Corporation, Dayton, Ohio.

Market Conditions

IN CHEMICAL, METALLURGICAL AND ALLIED INDUSTRIES

A Survey of the Economic and Commercial Factors That Influence Trade in Chemicals and Related Commodities—Prevailing Prices and Market Letters From Principal Industrial Centers

A Statistical Study of the Pulp and Paper Industry

The manufacture of paper pulp and its further fabrication into the various grades of paper is one of the chemically controlled industries for which accurate and comprehensive statistics are available. Through the services of the Federal Trade Commission, the commodity division in the Department of Commerce, and the active co-operation of the entire industry, paper manufacturers and consumers, and the general public as well, are provided with a reliable means for following conditions in this important industry.

These compilations prove beyond a doubt that the paper industry has already passed through the worst stage of the present business depression and is now distinctly on the road to improvement. To be sure, the total production figures for 1921 show a decrease of about 27 per cent as compared with 1920, but the real gain is in the monthly outputs. From Table I it will be noted that during the first 7 months of 1921 production dropped off at an alarming rate. From

TABLE I—DOMESTIC PRODUCTION AND SHIPMENTS OF ALL GRADES OF PAPER BY YEARS 1917 TO 1921

(Quantities in Net Tons.)

Month and Year	Monthly Production 1921	Monthly Production 1920	Monthly Shipment 1921	Monthly Shipment 1920
Total for All Grades				
January	420,468	650,293	385,923	646,715
February	407,966	564,500	383,679	532,336
March	440,777	641,343	416,668	656,658
April	422,012	634,402	425,584	622,913
May	383,995	645,413	386,671	662,587
June	403,657	657,322	405,959	668,082
July	370,429	658,518	379,672	657,360
August	442,519	654,158	448,054	652,998
September	477,926	643,018	489,128	648,295
October	542,408	621,964	560,558	613,324
November	535,876	518,144	531,606	499,281
December	508,284	445,539	503,567	423,986

Year	Annual Production	Annual Shipments
1921	5,356,317	5,317,069
1920	7,334,614	7,284,535
1919	6,190,361	6,225,904
1918	6,051,523	6,089,776
1917	5,919,647	5,838,286

420,500 net tons in January the output fell to 370,500 tons in July. Since then, however, the industry has made a remarkable recovery and is now on a production basis which compares favorably with the average for the last 5 years. According to the announcement of the Federal Trade Commission, we produced 506,195 net tons of paper in January, 1922, while the 5-year average for that month is only 504,175 tons.

The trend of production in the paper industry is shown graphically in Fig. 1, which is taken from the Harvard Economic Service's recent report on "The Volume of Manufacture." The adjusted index of 100 is based on the monthly averages for 1919. In discussing the relation of output to productive capacity of the paper industry, Babson makes the following statement: "Operations for 1921 were in the neighborhood of 60 per cent, as against about 90 per cent in 1920 and the rough average of 80 per cent for the 20 years previous thereto. The industry presented no evidence of undue expansion during the war, but since 1919 has increased in capacity at a rapid rate. From 1899 to 1919 the machine capacity grew about 220,000 tons per year. In 1920, however, the capacity increased 900,000 tons over 1919, and in 1921 further increased 650,000 tons over 1920. The number of companies engaged in the business decreased slightly between 1914 and 1919. Production is now estimated at about 70 per cent of capacity. It should be noted that the present capacity exceeds any probable demands during this year."

Production of all grades of paper decreased in 1921 as compared with 1920, the percentage of reduction varying from 39 per cent in the case of wallpaper to 17 in the case of tissue paper. Bag paper, which includes that made into flexible commercial containers such as grocery bags and flour sacks, and fine paper, such as writings, bonds and ledgers, also had very high rates of decrease. Book paper, which includes all periodical paper and miscellaneous grades

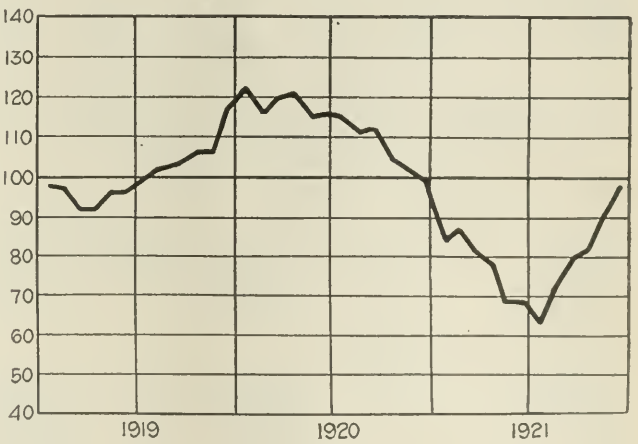

FIG. 1—THE TREND OF PRODUCTION IN THE PAPER INDUSTRY, 1919-1921

of machine finished, supercalendered and coated stock, decreased from 1,104,464 net tons in 1920 to 725,992 tons in 1921. It will be noted that stocks, on the other hand, were considerably larger during 1921 than in the preceding year.

Pulp Production and Stocks

A similar comparison of the production of wood pulp and the other kinds of pulp used in paper making is afforded by Table III. It will be noted that the decreases are in almost exactly the same proportion as in the case of paper. The bleached sulphite pulp shows the maximum reduction in output. Production for all grades of pulp in January, 1922, was 266,921 net tons, as compared with an average of 270,850 tons for the same month in 1919-1922. The Federal Trade Commission has the following to say regarding the ratio of stocks to average production:

"Comparing the stocks on hand at the domestic pulp mills at the end of January, 1922, with their average

CHEMICAL & METALLURGICAL ENGINEERING'S WEIGHTED INDEX OF CHEMICAL PRICES

Base = 100 for the year July 1, 1913, to June 30, 1914

This week	157.46
Last week	151.21
March, 1921	157
March, 1920	252
April, 1918 (high)	286
April, 1921 (low)	140

The index number has shown a gain of 6.25 during the past week and is now 14 points higher than the quotation for Jan. 25, 1922, which was the lowest level reached during the current year. This week's increase is due principally to the higher prices for ammonium sulphate, barium chloride, caustic soda and cottonseed oil. The only price reductions among the index commodities were for bleaching powder, soda ash and glycerine.

daily production based on the reports covering the years 1917, 1918, 1919, 1920, and 1921, the figures show that:

Ground wood pulp stocks equal 28 days' average output.

News grade sulphite mill stocks equal 9 days' average output.

Bleached sulphite mill stocks equal 5 days' average output.

Easy bleaching sulphite mill stocks equal 3 days' average output.

Mitscherlich sulphite mill stocks equal 6 days' average output.

Sulphate mill stocks equal 17 days' average output.

Soda pulp mill stocks equal 9 days' average output.

Mill stocks of "other than wood pulp" equal 5 days' average output.

Total mill stocks of all grades equal 16 days' average output."

Imports and Exports

Recent increase in the total imports of finished paper, combined with a 50 per cent reduction in exports during 1921, has been a matter of considerable concern to paper manufacturers. Newsprint, the bulk of which is imported from Canada, is the only grade of which the United States is a heavy importer. In 1921 newsprint showed about a 10 per cent increase both in quantity and value. Our foreign trade in paper during 1920 and 1921 and in pulp during the period 1918 to 1921 is shown in Table IV.

The Outlook for 1922

The most pressing problem now facing the paper manufacturers is the need for reducing costs of production. Although costs have receded considerably from the peak reached in 1920-21, they are still much higher than in 1913. To quote a second time from Babson: "Briefly, the outlook for the paper industry during 1922 is for continued readjustment of costs to prices with, nevertheless, a somewhat better demand for manufacture than was the case during 1921. Production should average about 70 per cent, or 6,200,000 lb. The most active period will probably be during the spring and fall months, with very quiet conditions in the summer. The spring activity will not be so good as the fall activity, due to the presence of fairly high stocks. Moreover, an improvement in general business conditions during the fall will then furnish greater stimulation."

Volume of Manufacture Will Increase in 1922

In a detailed report on this subject published Feb. 25, 1922, the Harvard Economic Service makes the following statement regarding future manufacture:

"There is a growing conviction that 1922 will witness a substantial increase of industrial output. Underlying factors are undoubtedly improving; liquidation is proceeding relentlessly; wages are being adjusted; prices are gradually assuming greater stability; agricultural prices in particular are exhibiting a definite tendency to rise. As these factors exert their favorable influence, production will undoubtedly respond. It seems to be generally conceded that consumption for the past year and a half has materially exceeded production. Stocks have been steadily reduced and there has been an increasing resort to current manufacturing to supply current consumption. It is this fact which accounts fundamentally for the rise in the volume of manufactures since last summer. There is every reason to believe that the same forces will operate cumulatively to stimulate production during 1922. With the evident improvement in underlying conditions, a rise in the volume of manufacture during 1922 is confidently predicted."

Many Far-Western Engineers Are Unemployed

Walter V. Brown, manager of the Employment Service of the American Engineering Council, has received a particularly discouraging report from his Californian representative regarding employment conditions on the Pacific Coast.

"The great question," said this report, "is: What is to become of the large percentage of engineers, long out of work and likely to stay so? Engineers do not earn so much that they can be idle for a year with impunity. Many here have gone into other business and others are ready to do the same at the first opportunity. There have been too many engineers turned out by the universities in late years. The market is glutted and it will be a good reaction if we see fewer in the near future."

Annual Reports and Dividend Announcements

Air Reduction Co.—C. E. Adams, president, stated in a recent letter to stockholders that the gross income of the company decreased from $7,189,767.37 in 1920 to $5,338,869.17 in 1921; and the net profits earned on the outstanding stock, before federal taxes, decreased from $1,256,439.93 in 1920 to $630,524.24 in 1921. The latter sum, however, was sufficient to pay the regular dividends out of current earnings.

Among other developments reported in the annual report was announcement of the purchase of control in the National Carbide Corporation. This assures the company of an ample supply of carbide for its own acetylene charging plants as well as for customer demands. Through the purchase of the Compressed Carbonic Co. in Baltimore, the company enters the liquid carbonic field and has already made satisfactory progress. During the year a new oxygen plant was built in Pittsburgh and a new acetylene plant in the Boston district. Commercial production of the "Airco Ignition Gauge" began in October, its active principle, neon, being obtained as a byproduct in the operation of the company's oxygen plants.

Allied Chemical & Dye Corporation—The regular quarterly dividend of 1¾ per cent was declared Feb. 28 on the preferred stock of this company, payable April 1, 1922, to stock of record on March 15, 1922.

Atlas Powder Co.—For the year ended Dec. 31, 1921, this company reported a net income of $634,484, which after allowing for preferred dividends was equal to $1.71 a share on the $5,515,985 common stock. In 1920 the company earned $1,434,693 and paid $16.32 per share on its common stock.

President W. J. Webster, in his letter to stockholders, pointed out that during the last 4 months of 1921 the company had actually earned $15.20 a share on its common stock, but because of greatly reduced inventory could show only $1.71 in its report.

Celluloid Co.—A dividend of 2 per cent upon the capital stock of this company has been declared, payable March 31 to stock of record March 8.

International Salt Co.—The regular quarterly dividend of 1¾ per cent has been declared on this company's capital stock. The dividend is payable April 1, 1922, to stockholders of record on March 15.

National Lead Co.—The report of this company for the year ended Dec. 31, 1921, shows a net income of $3,481,512, as compared with $4,735,509 in 1920. After deducting preferred dividends, the income in 1921 is equivalent to $8.59 per share on the common stock of $20,655,400. The 1920 dividend was $14.67.

United Dyewood Corporation—Dividends on both preferred and common stock of this corporation were announced March 1. The preferred dividend of $1.75 per share and the common of $1.50 are payable April 1 to stockholders of record March 15.

The St. Louis Market

St. Louis. March 2, 1922.

The recent activity in the heavy and industrial chemical market is still apparent with evidence of a broadening demand. Prices on the whole are very steady and the general trend appears to be toward higher levels. This is especially true on goods of foreign origin, where prices are being increased solely by the rising exchange. The weak spots in the market are becoming fewer and apparently the pressure toward downward revisions has passed, and prices today are based on actual production value and replacement conditions. Increased business is also manifested by the fact that the sales for February exceeded those for the corresponding month of last year by a large margin.

Alkalis

The alkali market remains firm with no price change since our report of Feb. 16; 76 per cent solid *caustic* is quoted at $3.40 per 100 lb. in carlots f.o.b. point of production, with 1- to 10-drum lots at $4@$4.10 delivered to buyer's door. The flake can be had at from 35 to 40c. per 100 lb. over the solid in all cases. There is no change in *soda ash*, prices still ranging from $2.40@$2.75 per 100 lb. for 58 per cent light in less than carlots. There is little doing in carlot buying. A buyers' market now prevails in *sal soda*, with a considerable range of prices.

General and Special Chemicals

Producers of heavy commercial mineral acids report the market very strong, especially the *nitric acid* group, price being based on 40 deg. at $7.40 per 100 lb. f.o.b. point of production and find no difficulty in getting business. *Sulphuric acid* is also very strong. *Muriatic acid* has had an overproduction; however, the price is firm. The decline of 1c. per lb. on *boric acid* last week has given way to a better demand and there is a freer movement. The low stocks of imported *citric acid* are stimulating a demand for domestic goods. This should be an opportune time to anticipate requirements, as prices have declined to a level where further reduction would net a loss to the producer. *Carbolic acid* is moving in a fair way. There has been no change in the *gallic acid* and *pyrogallic acid* movement. While the activities in the *phosphoric acid, U.S.P. sirupy*, market have not been altogether at a standstill, the increase has not been sufficient to give prices a firmer tone, but factors believe that complete recovery will be made in a short time and that a firmer market will then exist. Producers still report a sold-up position on *white arsenic* and are quoting in carlots at 7c. St. Louis. With the continued advance in the sterling exchange, *bismuth salts* and *iodide salts* are in greater demand than ever, and producers are well situated to meet this increase.

Glycerine has eased up some, and can be had at 16c. in drums, a decline of ¼c. in last week's price. *Sulphur* has shown a little more life recently, and while the price remains constant, it has been moving in greater volume. Inquiry and demand for *zinc sulphate, U.S.P.* continue to increase, with a fair demand for the technical grade, the latter being quoted at $2.95 in carlots f.o.b. St. Louis.

Linseed oil is still firm, the raw oil price having reached 92c. last week, and is now being offered at 91c. *Castor oil* advanced ¼c. during the last few days, now being held firmly at 13¼c. in drums; in quantities of 200 gal. this price can be bettered 1c. *Turpentine* is somewhat easier, and is being offered today at 91½c. in barrels.

A very unusual condition now prevailing in the paint industry is pessimism. The paint grinders, usually optimistic, are now showing signs of losing faith, and their attitude is evident in their purchasing. One of the largest paint grinders in St. Louis recently made the statement that at the rate he was now going it would be unnecessary to purchase any more raw material this season. Prices remain unchanged and demand very poor.

The New York Market

New York, March 6, 1922.

Changes in the price levels for a number of basic commodities are the outstanding developments of the week. Although the general trend of the market is undoubtedly upward, a number of leading producers have announced lower prices for such products as bleaching powder, glycerine, and zinc sulphate. On the other hand, there have been significant increases in the case of ammonium sulphate and cottonseed oil. Prices for caustic soda have not changed appreciably among the manufacturers, but the dealers report a noticeable firmness to the market. The export inquiry for caustic has continued and a few sales of moderate volume were reported.

There was no relief seen in the nitrite of soda market. A scarcity of imported material, together with a limited amount of domestic goods on the spot market, was chiefly responsible for the present situation. Some large producers of bleaching powder have reduced prices in order to compete successfully with importers. The first-hand market, as a result, reached the lowest price since May, 1919, when sales were recorded at 1½c. per lb. Prussiates have remained fairly firm, with odd lots in moderate demand. Zinc sulphate in carload quantities is a trifle lower.

Acetate of Soda—Some producers are not inclined to accept business in this chemical under 4½c. per lb. It is stated that large sales have been made to the dyestuff industry on this basis. Low-priced material that was

offered so freely has been partly absorbed and offerings are much scarcer.

Barium Chloride—Higher prices have been established on spot and it is doubtful if better than $58 per ton can be done for any quantity. Some sellers quote up to $60 per ton. The demand is good, with a higher market expected in the near future.

Bichromate of Potash—Sales of small lots on spot were recorded at 10¼c. per lb. Large sellers have shaded this figure to 10⅛c., while in some quarters as low as 10c. was heard. Business in only fairly moderate.

Bichromate of Soda—Trading on spot has shown no unusual activity. Dealers have sold small lots at 7¾c. per lb. Shipments are quoted at 7½c. The call for contract deliveries is steady among leading manufacturers.

Bleaching Powder—Foreign competition is being met by domestic producers and sales have gone through at the works as low as 1¾c. per lb. Imported material has been offered at $1.80 per 100 lb. ex-dock New York. The demand is not as active as in the early part of February.

Caustic Soda—Leading producers are maintaining the contract price of 2½c. per lb., basis 60 per cent, f.o.b. works. The demand is holding steady and shipments for the month of February have shown an increase over January. Dealers are quoting 3½c. per lb. for March shipment.

Lead Acetate — Large factors in this commodity have announced a cent per lb. reduction on all varieties. Prices range from 9§@12c. per lb. Business was reported a trifle better since the reduction.

Nitrite of Soda—Second hands are in possession of some limited quantities of domestic goods which are being offered at 8c. per lb. Producers are asking 8½c. per lb., f.o.b. works. Imported material is offered sparingly, with some small-lot sales recorded at 8c. per lb. early in the week. These sellers demand 8½c. at the close. The market is very firm.

Silicate of Soda—Large producers report sales to the consuming industries at $2.25 per 100 lb. in carload quantities for the 60 deg. Bé. Prices on the 40 deg. range from 85c. to $1.20 per 100 lb., depending on quantity.

Soda Ash—Lower prices have been established for soda ash at the works. Manufacturers offer light, 58 per cent, at $1.10 per 100 lb. in bulk, $1.20 in bags and $1.40 in barrels, basis 48 per cent, f.o.b. works. Spot and prompt shipments command a premium of 10c. per 100 lb. Dealers report sales of less than carload quantities at $1.95.

Zinc Carbonate—Producers are holding spot material at 14c. per lb. in barrels and 16c. in kegs. Moderate trading was reported at these figures.

Zinc Chloride—Domestic sales were reported by producers at 7½c. per lb. in carlots and 8c. in smaller quantities. The demand is fair.

Zinc Sulphate—Leading factors have reduced prices in large quantities ½c. per lb. and quote $2.75 per 100 lb. for prompt shipments. Business has improved to a noticeable extent since this reduction.

Vegetable Oils

Cottonseed Oil—The market during the past week was comparatively firm, reflecting the growing scarcity of crude material. New high figures were established at the close of trading. All short interests in the market were virtually liquidated. Winter oil on spot for domestic consumption was held around 13¼@13½c. per lb. Crude cottonseed sold at a new high mark, sales passing at 10¼@10½c. per lb., buyers' tanks, f.o.b. mills.

Linseed Oil—The market was easier, with fairly liberal offerings of imported material in several directions.

Fertilizers

Ammonium Sulphate—The market on this product has become one of the outstanding features in the chemical market. Spot supplies have practically disappeared and futures have been offered in only a very limited way. The export inquiry has become more active and unfilled orders for large quantities have been on the market for the past weeks. Material in double bags, f.a.s. N. Y., was quoted at 3c. per lb. Goods at the works are nominal, with a stray offering heard now and then at 2¾c. per lb.

The Iron and Steel Market

PITTSBURGH, March 3, 1922.

There has been a slight further increase in steel mill operations, the rate of steel ingot production at present being set at 29,000,000 tons a year, against 28,000,000 tons a fortnight ago, less than 18,000,000 tons at the end of December, and 23,000,000 tons last October and November, the highest rate since February a year ago.

Latest reports, not generally circulated as yet, are that there has been a noticeable falling off in buying of important finished steel products in the past week or 10 days. This might be regarded as quite natural in the circumstances, but the period of observation is too short to justify definite conclusions. A period of 30 days would be better.

The buying of steel has been widespread in character and is thoroughly healthy in that respect. There is even a fair percentage of railroad business, fully as much as could be expected in present railroad conditions. Even the agricultural implement trade, long the slackest of all the steel consumers, has been doing a little business. Demand for steel for the building trades is good rather than merely fair, seen particularly in standard steel pipe, both black and galvanized, and in sheets for metal lath, ceiling, eaves trough and conductor pipe, etc. The automobile trade is taking a natural proportion.

More Price Weakness

Some fresh price weakness has developed, although only in certain lines. Bars, shapes and plates, which got to an unexpectedly low level when they reached 1.40c. recently, are by no means rallying around that price, as in the Pittsburgh district lower prices have been made on certain large orders, while east and west the divergences from Pittsburgh basing have been more pronounced, the probability being that approximately 1.40c. f.o.b. mill has been done, representing very much less than 1.40c. f.o.b. Pittsburgh. In tubular goods the concessions from the regular lists have grown rather sharply in the past week or two, so much so that there is question whether new lists will not have to be issued.

In sheets the prices established more than 3 months ago, 2.25c. for blue annealed, 3c. for black and 4c. for galvanized, are still maintained, but this price steadiness, instead of being regarded as a support or stimulus to the steel market in general, is now regarded rather as an anomaly. The sheet prices present the curious phenomenon of affording a slight profit to the producers. Tinplate is in this category also, but that is not phenomenal, since tin plate is different from all other steel commodities and is promised a full demand for this year if not indeed a record demand.

The market in wire products is perhaps a trifle steadier. The special price of $2.40 on nails, as against the regular or official price of $2.50, has now become practically general, but on the other hand plain wire, instead of yielding correspondingly, seems to be steady at its regular price of 2.25c.

Pig Iron

Recent sales of basic pig iron on the basis of $17.75 valley are now regarded as making the market rather than as being exceptional and $18 is considered merely an asking price. Bessemer has sold in carload lots in the past week at its old price of $19.50, although there is little doubt that the $19 basis, done recently on a fair-sized lot, would apply on any tonnage. Foundry iron has sold more often at $19 valley than at $18.75.

Connellsville furnace coke has no more than held its recent advance to a range of $3.25@$3.50. Demand for coal, an important factor in coke prices, has decreased in the past 10 days, and the expectation that Connellsville operators could do better in the coal market than in the coke market is not yet justified. Foundry coke, however, has gone up some more, being now quotable strong at $4.25@$4.75, depending on brand, representing a straight advance of 50c. in 2 or 3 weeks.

The Pittsburgh Steel Co. and the Jones & Laughlin Steel Co., long absent from the scrap market, have in the past few days bought more than 10,000 tons of heavy melting steel, the reported price being $15. Dealers had been bidding $14 @$14.50 for odd lots as they appeared.

General Chemicals

CURRENT WHOLESALE PRICES IN NEW YORK MARKET

		Carlots	Less Carlots
Acetic anhydride	lb.	..... –	$0.40 – $0.42
Acetone	lb.	$0.12½ – $0.12½	.13 – .13½

Coal-Tar Products

NOTE—The following prices are for original packages in large quantities:

Alpha-naphthol, crude	lb.	$1.00 — $1.05
Alpha-naphthol, refined	lb.	1.10 — 1.15
Alpha-naphthylamine	lb.	.29 — .30
Aniline oil, drums extra	lb.	.16½ — .17
Aniline salts	lb.	.24 — .26
Anthracene, 80% in drums (100 lb.)	lb.	.75 — 1.00
Benzaldehyde U.S.P.	lb.	1.25 — 1.30
Benzidine, base	lb.	.85 — .95
Benzidine sulphate	lb	.75 — .85
Benzoic acid, U.S.P.	lb.	.60 — .65
Benzoate of soda, U.S.P.	lb.	.55 — .57
Benzene, pure, water-white, in drums (100 gal.)	gal.	.29 — .35
Benzene, 90%, in drums (100 gal.)	gal.	.27 — .32
Benzyl chloride, 95-97%, refined	lb.	.25 — .27
Benzyl chloride, tech.	lb.	.20 — .23
Beta-naphthol benzoate	lb.	3.75 — 4.00
Beta-naphthol, sublimed	lb.	.60 — .65
Beta-naphthol, tech	lb.	.27 — .30
Beta-naphthyla mine, sublimed	lb.	1.50 — 1.60
Cresol, U. S. P., in drums (100 lb.)	lb.	.15 — .16
Ortho-cresol, in drums (100 lb.)	lb.	.18 — .20
Cresylic acid, 97–99%, straw color, in drums	gal.	.50 — .52
Cresylic acid, 95-97%, dark, in drums	gal.	.45 — .47
Dichlorbenzene	lb.	.06 — .09
Diethylaniline	lb.	1.10 — 1.15
Dimethylaniline	lb.	.38 — .40
Dinitrobenzene	lb.	.22 — .25
Dinitroclorbenzene	lb.	.23 — .25
Dinitronaphthalene	lb.	.32 — .35
Dinitrophenol	lb.	.35 — .38
Dinitrotoluene	lb.	.22 — .24
Dip oil, 25%, car lots, in drums	gal.	.24 — .26
Dipnenylamine	lb.	.59 — .70
H-acid	lb.	.90 — 1.00
Meta-phenylenediamine	lb.	.95 — 1.00
Monochlorbenzene	lb.	.12 — .15
Monoethylaniline	lb.	1.20 — 1.25
Naphthalene crushed, in bbls.	lb.	.06½ — .07
Naphthalene, flake	lb.	.06½ — .07½
Naphthalene, balls	lb.	.07½ — .08½
Naphthionic acid, crude	lb.	.65 — .70
Nitrobenzene	lb.	.10 — .12
Nitro-naphthalene	lb.	.30 — .35
Nitro-toluene	lb.	.15 — .17½
Ortho-amidophenol	lb.	2.75 — 2.80
Ortho-dichlor-benzene	lb.	.15 — .20
Ortho-nitro-phenol	lb.	.75 — 80
Ortho-nitro-toluene	lb.	.15 — .20
Ortho-toluidine	lb.	.20 — .25
Para-amidophenol, base	lb.	1.25 — 1.30
Para-amidophenol, HCl	lb.	1.30 — 1.35
Para-dichlorbenzene	lb.	.15 — 18
Paranitroaniline	lb.	.75 — .77
Para-nitrotoluene	lb.	.70 — .75
Para-phenylenediamine	lb.	1.50 — 1.55
Para-toluidine	lb.	1.10 — 1.15
Phthalic anhydride	lb.	.35 — .38

Phenol, U. S. P., drums	lb.	.11½ —	.15
Pyridine	gal.	1.75 —	2.75
Resorcinol, technical	lb.	1.25 —	1.30
Resorcinol, pure	lb.	1.80 —	1.95
Salicylic acid, tech., in bbls.	lb.	.18 —	.20
Salicylic acid, U. S. P.	lb.	.22 —	.23
Salol	lb.	.80 —	.82
Solvent naphtha, water-white, in drums, 100 gal.	gal.	.25 —	.28
Solvent naphtha, crude, heavy, in drums, 100 gal.	gal.	.12 —	.14
Sulphanilic acid, crude	lb.	.25 —	.27
Tolidine	lb.	1.20 —	1.30
Toluidine, mixed	lb.	.32 —	.38
Toluene, in tank cars	gal.	.25 —	.28
Toluene, in drums	gal.	.30 —	.35
Xylidines, drums, 100 gal.	lb.	.40 —	.45
Xylene, pure, in drums	gal.	.40 —	.45
Xylene, pure, in tank cars	gal.	.45 —	....
Xylene, commercial, in drums, 100 gal.	gal.	.33 —	.35
Xylene, commercial, in tank cars	gal.	.30 —	....

Waxes

Candellila Wax.....25-26c. per lb.
Carnauba Wax—No. 3—North Country....15½-16c. per lb.

All other prices remain quotably unchanged.

Naval Stores

All prices are f.o.b. New York unless otherwise stated, and are based on carload lots. The oils in 50-gal. bbls., gross weight, 500 lb.

Rosin B-D, bbl	280 lb.	$5.30 —	5.35
Rosin E-I	280 lb.	5.40 —	5.45

Industrial

Financial, Construction and Manufacturers' News

Construction and Operation

Alabama

ROBERSTDALE — The Sanford-Seever Orchard Co. is planning for the construction of a new gas-producer plant at its properties.

DOTHAN—Fire, Feb. 14, destroyed a portion of the refining plant of the Dothan Syrup Co., with loss estimated at about $75,000, including equipment.

Arizona

JEROME—The United Verde Copper Co. is completing plans for the construction of a new crushing plant at Clarkdale, Ariz., estimated to cost about $1,500,000, with machinery. Contract for foundation work has been let to Twohy Bros., Phœnix, Ariz., at a cost of approximately $150,000.

California

BURBANK—The American Aluminum-Metal Products Co. has awarded a contract to R. W. McCrea, Huntington Park, Cal., for the erection of its proposed new local plant, comprising a group of seven buildings, estimated to cost in excess of $90,000. Richard D. King, 519 Van Nuys Bldg., Los Angeles, is architect.

Florida

CHULUOTA—The Petrous Mfg. Co., recently organized with a capital of $50,000, is planning for the erection of a 2-story plant, 40 x 85 ft., for the manufacture of cement brick and kindred products. The works will be equipped for an initial daily output of 30,000 bricks. Frank Wheeler is president; J. A. Rogers is secretary and treasurer in charge.

FORT PIERCE—The Gulf Sugar Corp. has completed plans and will soon commence the erection of a new sugar refinery on local site, with initial capacity of about 100 tons per day.

SEABREEZE—The Town Council has plans under way for the installation of a water-softening plant in connection with extensions and improvements to the waterworks system.

Georgia

ATLANTA—The White Provision Co. is planning for the erection of a new fertilizer works at its plant. The capacity of the lard refinery will be increased with the installation of new equipment. The company will also build a new electric power plant. The capital has recently been increased to $1,000,000 for expansion. W. H. White, Jr., is president.

Illinois

BRISHENE—The Western Union Telegraph Co., Van Buren near Scott St., Joliet, Ill., has plans under way for the erection of a new creosoting plant for pole treatment at Frankfort, near Brishene, estimated to cost about $60,000, including equipment.

Indiana

BLOOMINGTON—The Bloomington Brick & Tile Co. has plans nearing completion for the construction of a new plant at Unionville, near Bloomington, for the manufacture of brick, tile and other burned clay products, estimated to cost about $250,000, including machinery. The company is arranging for the financing of the project. A. W. Beecher is president.

Kentucky

CATLETTSBURG—The Great Eastern Refining Co., recently organized with a capital of $200,000, A. J. Dalton, Huntington, W. Va., president, is planning for the erection of a new oil-refining plant at Leach, near Catlettsburg, with initial capacity of about 500 bbl. A site has been selected and work will be commenced at an early date. The equipment installation will include agitators, stills, tanks, and general operating machinery. T. H. Gilman is general manager.

Maryland

BALTIMORE—The Standard Oil Co., Pratt and Commercial Sts., has completed plans for the construction of a 2-story chemical mixing and pumping plant on Third Ave., near Second St.

TEXAS—The J. B. Logan Lime Co. will install a new 30-in. grinding mill at its plant.

BALTIMORE—The Pompeian Romanza Corp., recently organized with a capital of $1,760,000, has acquired the plant, property and equipment of Musher & Co., manufacturer of olive oil products, at Fayette and 11th Sts., for a consideration said to be $600,000. The new owner will use the plant for the manufacture of edible oils, compounds, etc., and will commence operations at an early date. It is headed by W. W. and W. H. Cook, and W. H. Hamilton.

Massachusetts

MALDEN—The Silex Co. of Massachusetts has acquired the factory of the Franklin Rubber Co., 926 Eastern Ave., for the operation of a plant for the manufacture of glass products.

FALL RIVER—The Atlantic Refining Co., 3144 Passyunk Ave., Philadelphia, manufacturer of refined oil products, is planning for the erection of a new plant at the foot of Slade St., Fall River, estimated to cost close to $1,000,000, including equipment. Metzger & Fisher, Otis Bldg., Philadelphia, are contractors for certain features of the project.

Michigan

CADILLAC—The new plant of the Cadillac Lumber & Chemical Co., to be located at Sault Ste. Marie, Mich., will consist of a number of buildings, estimated to cost in excess of $150,000, including machinery. The plant will have a department for the production of acetate of lime, with capacity of about 2 cars a week; for the manufacture of wood alcohol, charcoal and other affiliated products. Work will be commenced early in the spring, and will be pushed to completion. It is expected to give employment to more than 400 persons. The present plant will be removed to this location. The company is operating with a capital of $1,000,000.

IONA—The Michigan Porcelain Tile Co. has completed plans and will take bids at once for the erection of a new 1-story and basement plant, 120 x 155 ft., estimated to cost about $42,000. P. Lindout, 5th floor, Michigan Trust Bldg., Grand Rapids, is architect. H. Kidder is general manager.

Missouri

ST. CHARLES—The Weldon Spring Quarry, recently organized, is planning for the establishment of a lime-fertilizer plant, in connection with its quarry properties in this section, with a daily capacity of about 2 carloads of material. A rock-crushing plant will be installed with daily output of about 6 carloads of crushed material.

KANSAS CITY—The Lion Oil & Refining Co. is planning for the installation of new equipment at its plant, including agitator, tanks, etc. The company will construct a new pipe line to cost about $80,000. Victor H. Smith is general manager.

New Jersey

NEWARK—The United Butchers' Fat & Reducing Co., Doremus Ave., has filed plans for the erection of its proposed new plant, consisting of a main factory to cost about $23,000, power house, garage and other operating buildings. The plant will be used for the manufacture of soaps, greases, etc.

PERTH AMBOY—Fire, Feb. 23, destroyed a portion of the chemical plant of the Novo Laboratories, 651 Catherine St., with loss estimated at about $15,000.

New York

NEW YORK—The New Amsterdam Gas Co., 130 East 15th St., has filed plans for the construction of a new laboratory and switch house, 63 x 107 ft., at its plant at 403-7 East 40th St., to cost about $100,000. William Whitehill, Buckley-Newhall Bldg., 6th Ave and 41st St., is architect and engineer.

NEW YORK—Fire, Feb. 21, damaged a portion of the plant of the Redding Chemical Works, Inc., 329 East 47th St., manufacturer of printing and lithographing inks. An official estimate of the loss has not been announced.

Oklahoma

SAYRE—The Common Council will install a new filtration plant in connection with extensions and improvements in the waterworks system.

MADILL—The Common Council is planning for the construction of a filtration plant and other improvements at the municipal waterworks to cost about $500,000.

Pennsylvania

LOCK HAVEN—The American Aniline Products Co. is planning for the erection of a 2-story and basement plant building, 200 x 250 ft., to replace the factory recently destroyed by fire with loss of about $150,000. The new structure will cost a like amount. Headquarters of the company are at 80 5th Ave., New York, N. Y.

FAIRCHANCE—The Quertinmont Glass Co., manufacturer of window glass, has preliminary plans under way for the erection of a new plant at Fairchance, to be of "five-pot" initial capacity, giving employment to more than 500 operatives. A new process of glass manufacture will be used. It is expected to have the plant ready for operation in the fall, with additional plant units to be built in 1923. Jules J. Quertinmont is president.

PITTSBURGH—Fire, Feb. 17, destroyed a portion of the plant of the Walker Chemical Co., McCartney St., West End, with loss estimated at about $10,000.

CHESTER—The Scott Paper Co., foot of Market St., Philadelphia, Pa., has taken bids for the rebuilding of a 2-story factory at its works at Chester, 45 x 85 ft.

PITTSBURGH—The Creative Chemical Co. has filed plans for the erection of a new 1-story building at 4616-20 Friendship Ave.

HIGHSPIRE—The Keystone Carbonic Gas Co., recently organized, has acquired the local plant of the Highspir Distillery Co., for the establishment of a new plant for the manufacture of acid gas. The plant will be remodeled and improved, and a carbonic gas laboratory, totaling about 21,000 sq.ft. of floor area, constructed. S. S. Bailey is president, and E. W. Powell, secretary.

Tennessee

GREENBACK—The Greenback Brick Co. is planning for the erection of a new plant for the manufacture of brick and other burned clay products, with initial capacity of about 30,000 bricks per day. J. L. Jones is proprietor and general manager.

MT. PLEASANT—Fire, Feb. 23, destroyed the grinding plant of the Charleston Mining & Mfg. Co., with loss estimated at about $100,000, including machinery. It is planned to rebuild.

Texas

DALLAS—Fire, Feb. 20, destroyed a portion of the plant of the Hesse Envelope Co., Carter and Caruth Sts., manufacturer of paper products, with loss estimated at about $100,000, including machinery. George S. Otey is president.

Virginia

WOODSTOCK—The Hygrade Manganese Co., operating properties in the Cedar Creek Valley section, has taken out a state charter, with capital of $100,000, to provide for general expansion. The company will acquire lands to the extent of 3,000 acres and open up new properties as required. N. H. Manafee is president, and Charles B. Massie, vice-president.

West Virginia

NITRO—The Southern Dyestuffs Co. is planning for the installation of machinery in a number of buildings at its local plant for the manufacture of dyesuffs and intermediates. The extension will give employment to about 200 men.

KANAWHA CITY—The Libbey-Owens Sheet Glass Co. will make extensions and improvements in its plant at Kanawha City, to cost about $200,000, including a new power plant and other buildings.

New Companies

THE PYRALAC CHEMICAL CO., Newark, N. J., has been incorporated with a capital of $25,000, to manufacture chemicals and chemical byproducts. The incorporators are Ira Bingham, M. M. Fast and George N. Bick, 71 Paris St., Newark.

THE KEMO PRODUCTS CO., Rochester, N. Y., has been incorporated with a capital of $25,000, to manufacture chemicals and chemical byproducts. The incorporators are E. N. Barber, R. G. Fisher and S. E. Godden. The company is represented by Lynn Bros., attorneys, Rochester.

THE AMERICAN TIRE WORKS, INC., Pawtucket, R. I., has been incorporated with a capital of $50,000, to manufacture automobile tires and other rubber products. The incorporators are John T. Burke, D. and Nathan Siegelman, 50 Central Ave., Pawtucket.

THE SILVER FLASH OIL CO., 115 North Charles St., Baltimore, Md., has been incorporated with a capital of $100,000, to manufacture petroleum products. The incorporators are Otto C. Peterman, Silas Murray and Stanley C. Edmister.

THE CROWN FOUNDRY CO., Hersheel St., East Peoria, Ill., has been incorporated with a capital of $16,000, to manufacture iron, steel and other metal castings. The incorporators are Frank Barr, J. D. Armstrong and O. B. Slater.

THE NEW YORK COAL-TAR PRODUCTS & CHEMICAL CO., New York, N. Y., has been incorporated under Delaware laws with a capital of $1,000,000, to manufacture chemicals and affiliated products. The company is represented by the Corporation Guarantee & Trust Co., Land Title Bldg., Philadelphia, Pa.

THE KEYSTONE REFRACTORIES CO., Jersey City, N. J., has been incorporated with a capital of $10,000, to manufacture firebrick and other refractory products. The incorporators are J. W. Young, F. W. Beisman and L. E. Turk, 3 Foy Place, Jersey City.

THE SUNNYSIDE BRONZE FOUNDRY, New York, N. Y., has been incorporated with a capital of $5,000, to manufacture bronze and brass castings. The incorporators are K. Rippel, J. Forman and O. S. Berger. The company is represented by Abraham Lipton, 160 Broadway, New York.

THE TYCOON OIL CO., Erlanger, near Covington, Ky., has been incorporated with a capital of $50,000, to manufacture petroleum products. The incorporators are J. B. Respress, Erlanger; Benjamin Berkshire, Petersburg, Ky.; and E. B. Terrell, Covington, Ky.

THE ATLAS CHEMICAL LABORATORIES, INC., 1717 Mosher St., Baltimore, Md., has been incorporated with a capital of $50,000, to manufacture chemicals, acids, fertilizers and kindred products. The incorporators are B. L. Auld, John E. Auld, Sr., and Joseph Lichtenberg.

THE INDE-PENN OIL & REFINING CO., 223 North Galena Ave., Dixon, Ill., has been incorporated with a capital of $50,000, to manufacture petroleum products. The incorporators are Chester V. Chapman, Floyd D. Chapman and George F. Prescott.

THE ZENITH CHEMICAL CO., 285 South 20th St., Newark, N. J., has filed notice of organization to manufacture chemicals and chemical byproducts. The company is headed by Bernard W. VonSmuda, 343 16th Ave., Irvington, Newark.

THE LEVIN CO., 607 Nogalitos St., San Antonio, Tex., has been incorporated with a capital of $10,000, to manufacture lubricants and kindred oil products. Nathan Levin is president, and W. P. Gee, vice-president.

THE ACID-PROOF BRONZE CO., Pittsburgh, Pa., has been incorporated under Delaware laws, with capital of $200,000, to manufacture special bronze and other metal products. The incorporators are John P. and W. R. Kegg, and J. J. Elling, Pittsburgh. The company is represented by the Corporation Service Co., Wilmington, Del.

THE GREAT NORTHEASTERN CHEMICAL CO., 1362 Dorchester Ave., Boston, Mass., has filed notice of organization to manufacture chemicals and chemical byproducts. The company is headed by Richard Fine.

JAYNE & SIDEBOTTOM, New York, N. Y., have been incorporated with a capital of $10,000, to manufacture chemicals and kindred products. The incorporators are D. W. Jayne, H. G. Sidebottom and L. T. McManus. The company is represented by McKerchery & Link, 40 Rector St., New York.

THE TAYLOR-KENTUCKY OIL CO., 716 Fidelity Bldg., Baltimore, Md., has been incorporated with a capital of $750,000, to manufacture petroleum products. The incorporators are Morgan J. Cramer, Josiah and John R. Speer.

THE STAUDT & NEUMANN CO., 13 South Broadway, Aurora, Ill., has been incorporated with a capital of $36,000, to manufacture chemicals, chemical byproducts, drugs, etc. The incorporators are Louis C. and Albert J. Staudt, and Herbert L. Neumann.

THE METZ PLATINUM REFINING CO., 42 Walnut St., Newark, N. J., has filed notice of organization to manufacture refined metals. Werner P. Metz, 470 Belmont Ave., heads the company.

THE COMMONWEALTH DRUG & CHEMICAL CO., Philadelphia, Pa., has been incorporated under Delaware laws, with a capital of $100,000, to manufacture chemicals, chemical byproducts, drugs, etc. The incorporators are R. Lincoln and Hodge Lester, and H. L. Adams, Philadelphia. The company is represented by the Capital Trust Co. of Delaware, Dover, Del.

THE TRI-CITY BRICK CO., Second Ave. and 18th St., Rock Island, Ill., has been incorporated with a capital of $60,000, to manufacture brick, tile and other burned clay products. The incorporators are S. M. and J. L. Buckley, and H. O. Binyon.

THE RADIUM CHEMICAL CO., 44 Front St., Worcester, Mass., has filed notice of organization to manufacture chemicals and chemical byproducts. The company is headed by James W. Lecuyer and Frank S. Walker.

THE NEW JERSEY METAL TREATMENT CO., Newark, N. J., has been incorporated with a capital of $4,000, to manufacture special metals. The incorporators are Adolph Doll and Alexander Ross, 482 18th Ave., Newark.

THE QUAKER PAINT CO., Philadelphia, Pa., has been incorporated with a capital of $25,000, to manufacture paints, varnishes, etc. Ferdinand Ambacher, 1236 West Airdrie St., Philadelphia, is treasurer.

THE MODERN BRASS FOUNDRY CO., Indianapolis, Ind., has been incorporated with a capital of $25,000, to manufacture brass, bronze and aluminum castings. The incorporators are Fred W., Ralph N. and Pulaski E. Smith, all of Indianapolis.

THE K. I. HERMAN CHEMICAL CORP., 38 South Dearborn St., Chicago, Ill., has been incorporated with a capital of $300,000, to manufacture chemicals and chemical byproducts. The incorporators are K. I. Herman, R. E. Maurer and George J. Koreck.

THE PEERLESS CORK CO., 26 Prospect St., Newark, N. J., has filed notice of organization to manufacture cork products, seals, etc. The company is headed by Charles A. Hauser, 61 Linden Ave., Irvington, Newark.

THE LIBERTY COLOR & CHEMICAL CO., Philadelphia, Pa., has been organized to manufacture chemicals, chemical byproducts, dyes, etc. The incorporators are Thomas J. Grady, Thomas D. O'Brien and Robert J. Tracey. The company is represented by Charles A. Waters, 1208 Widener Bldg., Philadelphia.

THE ASSOCIATED REFINERIES CO., Denison, Tex., has been incorporated with a capital of $15,000, to manufacture petroleum products. The incorporators are V. H. Williams, M. R. Murray and George P. Blair, all of Denison.

HAYES-DEPRATO, INC., Ferndale, Mich., has been incorporated with a capital of $50,000, to manufacture paints, varnishes, etc. The incorporators are W. A. Wooliver, N. J. Deprato and W. P. Hayes, 6104 Crane Ave., Detroit, Mich.

THE PHOSPHO ALBUMEN CO., Newburgh, N. Y., has been incorporated with a capital of $30,000, to manufacture chemical specialties. The incorporators are R. H., J., and R. H. Cathcart, Jr., Newburgh. The company is represented by J. Witschief, attorney, Newburgh.

THE ROYALCROSS CO., Brooklyn, N. Y., has been incorporated with a capital of $50,000, to manufacture extracts, oils, etc. The incorporators are A. M. Wilson and M. Levine. The company is represented by J. B. Baer, 2 Rector St., New York.

THE FRAZIER CUSHION CORD TIRE CO., Wheeling, W. Va., has been incorporated with a capital of $75,000, to manufacture automobile tires and other rubber products. The incorporators are M. J. Cullinan and F. L. Schmidt, Wheeling; and Tuman Frazier, Martins Ferry, O.

THE OSCEOLA TURPENTINE CO., Deer Park, Fla., has been incorporated with a capital of $25,000, to manufacture turpentine and affiliated products. J. G. Henderson, Deer Park, is president; and J. H. Blount, secretary-treasurer, Jacksonville, Fla.

THE INDEPENDENT FLUORSPAR CO., Wilmington, Del., has been incorporated under state laws with a capital of $100,000, to operate fluorspar properties and produce commercial fluorspar. The company is represented by the Colonial Charter Co., Ford Bldg., Wilmington.

Capital Increases, etc.

THE DUFFNEY BRICK CO., Mechanicsville, N. Y., has filed notice of increase in capital to $110,000.

THE NEW EGYPTIAN PORTLAND CEMENT CO., Detroit, Mich., has filed notice of increase in capital from $500,000 to $1,000,000.

THE LIBERTY CHEMICAL WORKS, 352 East Illinois St., Chicago, Ill., has filed notice of increase in capital from $20,000 to $30,000.

THE MUSKOGEE VITRIFIED BRICK CO., Muskogee, Okla., has filed notice of increase in capital from $100,000 to $125,000. F. C. Nicholson is president.

THE ALUMNADA LEAD CO., Warren, Ariz., has filed notice of increase in capital from $1,000,000 to $1,300,000.

THE WEIRTON STEEL CO., Wierton, W. Va., has arranged for a bond issue of $1,000,000, for general operations and financing. E. T. Weir is president.

THE MORTON SALT CO., 80 East Jackson Blvd., Chicago, Ill., has filed notice of increase from $5,200,000 to $6,200,000.

CORD A. MYER, Tarrytown, N. Y., manufacturer of cement, has filed a voluntary petition in bankruptcy with liabilities stated at $257,315.

The plant of the ZIRCONIUM CO. OF AMERICA, Monument and 11th Sts., Baltimore, Md., manufacturer of metal products, has been acquired at a receiver's sale by William T. Larkin.

C. W. Johnson has been appointed receiver for the AETNA REFINING CO., Louisville, Ky., operating an oil refinery.

THE SUTHERLAND PAPER CO., Kalamazoo, Mich., has filed notice of increase in capital from $1,000,000 to $1,500,000.

Coming Meetings and Events

AMERICAN CHEMICAL SOCIETY will hold its spring meeting at Birmingham, Ala., April 4 to 7, 1922.

AMERICAN ELECTROCHEMICAL SOCIETY will hold its spring meeting in Baltimore, April 27, 28 and 29, 1922. Headquarters will be at the Emerson Hotel.

AMERICAN FOUNDRYMEN'S ASSOCIATION will hold its next convention and exhibit at Rochester, N. Y., during the week of June 5, 1922. Meetings will be held in the spring instead of in the fall as heretofore

AMERICAN INSTITUTE OF CHEMICAL ENGINEERS will hold its summer meeting at Niagara Falls, June 19 to 22. Headquarters will be at the Clifton Hotel.

AMERICAN SOCIETY FOR STEEL TREATING will hold a sectional meeting at the Bureau of Mines auditorium, Pittsburgh, Pa., on May 25 and 26. The International Steel Exposition and Convention of the society will be held in the General Motors Bldg., Detroit, Mich., Oct. 2 to 7.

AMERICAN SOCIETY FOR TESTING MATERIALS will hold its twenty-fifth annual meeting June 26 to July 1, at Atlantic City, N. J. Headquarters will be at the Chalfonte-Haddon Hall Hotel.

INTERNATIONAL UNION OF PURE AND APPLIED CHEMISTRY will hold a meeting at Lyons, France, June 27 to 30.

IRON AND STEEL INSTITUTE (British) will hold its annual meeting on May 4 and 5 at the House of the Institution of Civil Engineers, Great George St., S. W., 1, London.

NEW JERSEY CHEMICAL SOCIETY holds a meeting at Stetters Restaurant, 842 Broad St., Newark, N. J., the second Monday of every month.

STAMFORD CHEMICAL SOCIETY, Stamford, Conn., holds a meeting in the lecture room of the local high school on the fourth Monday of each month, except June, July, August and September.

The following meetings are scheduled to be held in Rumford Hall, the Chemists Club, New York: March 10—American Chemical Society; March 24—Society of Chemical Industry, regular meeting; April 21—Society of Chemical Industry (in charge), American Electrochemical Society, Société de Chimie Industrielle, American Chemical Society, joint meeting; May 5—American Chemical Society, regular meeting; May 12—Société de Chimie Industrielle (in charge), American Chemical Society, Society of Chemical Industry, American Electrochemical Society, joint meeting; May 19—Society of Chemical Industry, regular meeting: June 9—American Chemical Society, regular meeting.

Laying the Foundation For Our Foreign Trade

NOT all the news that comes from Washington these days is proving a menance to business. Happily the recent rumors that the Department of Commerce is to receive an increased appropriation have at last been confirmed. The Senate Committee on Commerce has reported out a bill which, if finally approved, will give the Bureau of Foreign and Domestic Commerce about $450,000 more than its appropriation of last year. To be sure, $750,000 had been asked by Mr. HOOVER and this amount had received the approval of the Director of the Budget, but in view of the tight-fisted policies of the present Congress on all except vote-getting expenditures, the country can well rejoice at the committee's apparent far-sightedness.

It is to be hoped that this is the beginning of a broader view of our foreign trade. Consular service and other active agencies for trade information lie at the very foundation of commerce and logically that is where we should begin to build. The dominating overseas trade of Great Britain and pre-war Germany had been developed around consular and commercial services that formed a network extending to the four quarters of the globe. England in particular has spent centuries in developing sources of trade information and keeping the avenues of commerce open to her merchants.

It is largely to these activities that the British merchant marine owes its enviable development. With merchants and agents in every port selling and urging the sale of British goods, the groundwork was laid for a foreign trade which naturally was carried in British vessels. Perhaps our own lawmakers may yet realize that subsidies for American shipping and government extension of credits are necessary only because we have neglected our foreign commerce. An intensive study of foreign markets is logically the first step in reconstructing our fast diminishing export trade.

An additional justification of the increased appropriation for the Department of Commerce is to be found in the program awaiting the recently authorized foreign debt commission. The recommendations of this commission in regard to the ten billion dollars now owed to the United States must be based on accurate knowledge of economic conditions in Europe. Naturally its members will look to Secretary HOOVER and his department for much of this essential information.

Finally, the chemical industry has its own selfish reasons for rejoicing. Secretary HOOVER'S plans for enlarging the work of his department call for a number of new commodity divisions and among the first to be established will be the one devoted to the dye and chemical industries. The need for this division is already evident and we are looking forward patiently to its organization. The increase in appropriations, which will make possible these extended activities, must yet be approved by the Senate and agreed to by the conferees, but it is hoped that the good work once started will proceed to its completion.

"Free Information Service"

SOME consulting chemical engineers have apparently had misgivings over the recent announcement by the National Research Council of "free information service." They have thought this announcement was an evidence that the Council was about to enter into competition with them and encroach upon the legitimate field by free consulting service. If this were the fact, there would be great point in the comment which has been made; but fortunately it is quite clear that such is not the Council's intent.

The Research Information Service, which made the announcement referred to, is one of the divisions of the Council. Its purpose is to assist investigators by answering questions or placing these investigators in touch with sources of information from which aid of any sort may be had. Many times the ability to get a needed fact, a needed reference, a needed piece of apparatus, will accelerate research tremendously. Indeed, this may be sufficient to permit continuance of work that otherwise would be abandoned through discouragement of the investigator. One of the purposes of the Service is to supply such assistance. In this effort it should inspire the commendation of all.

In general the Service is being extended only slightly beyond the field of assistance to the private individual or the investigator in collegiate work. Its effort in technical and commercial problems is limited by the meager funds available. In most cases the queries which come to the Council would not otherwise go to any commercial or consulting agency. But by assistance to the few industrial inquirers who ask aid, the Information Service undertakes primarily to build up an appreciation of and a desire for more results of research. And where the inquirer appears to be a firm or individual who should make use of professional consultants, reference is made to such sources.

Free service by the Council, an endowed quasi-public body, in competition with the consulting profession would be inexcusable. The Council recognizes this fact. Instead, it desires to build up the most friendly co-operative arrangement with the consulting profession at large. Indeed, it hopes that the appreciation of research and the stimulus to research from its work will be such as to increase the demand for consulting service and thus make more widespread the use of experienced and competent advisers. On this basis certainly the consulting profession can co-operate.

The Chemist And the Lawyer

ON FEBRUARY 13 last *The Financier* of London published an article several columns in length on "Chemicals and Chemical Engineering." The purpose was to show the rapid rise of British chemical industry under the stress of war, the ubiquitous need of the chemist throughout industry, the prompt and efficient answer that the British chemist made to the call for his services, and the gradual let-down that has taken place in British chemical industry since the war.

All we need to do is to change a few names and the article would be timely here. The reason for the let-down we believe to be the same in both countries. It is only partly economic. Another very potent cause applies, we believe, to both American and British chemists in similar measure, and we propose to look for it among the chemists themselves rather than among manufacturers or purchasers of materials or the general public.

The relation of the chemist to industry is substantially the same as that of the lawyer to business. The lawyer draws contracts and provides for the avoidance of error in transactions. With his aid associations are formed and selling and distribution are carried on. But the chemist produces the goods. Why is it, then, that the actual producer of goods is a kind of hired man, as often as not required to punch the time-clock, while the lawyer receives the manufacturer in his own office, charges him a month's salary of a chemist for an hour's discussion and a letter in relation to matters of less importance than the work of the chemist?

During the war the chemist, being needed, was exalted until he scarcely knew himself. His advice was constantly asked for and taken, and he sat in the seats of the mighty. The war over, he finds himself in most cases back in the position of a hired man again. Why is it?

It is not competition that does it, for there are more lawyers than chemists, and there is, in point of fact, more real work for chemists to do than there is for lawyers. True, there is a certain glamour, a tradition of distinction, that attaches itself to the legal profession which is lacking in that of chemistry, but in spite of this, the profession of law has many members who are unfit for decent society; a large number of them have no background of culture whatever. On the other hand, there are always enough lawyers of eminence and prominence to maintain the tone; to keep up what the Chinese call the "face" of the profession; to present a very taking front.

Chemists are lacking in this quality of well-known-ness among their number, and the question is fair whether they have not principally themselves to blame. If we consider the relations of present-day lawyers to public affairs compared to that of present-day chemists, it looks almost as though chemists were not interested. There is one chemist in the U. S. Senate, and we have lately read of a professor of chemistry who is president of a local chamber of commerce. We are disposed to make a fuss over it as a triumph. Instead of being a triumph it is a confession.

How many American chemists are there who can speak with the grace, the *savoir faire*, the distinction of Dr. EDGAR FAHS SMITH? If there are any they are remarkably silent! The literature of chemistry is no more technical or uninteresting to the layman than that of law. But men who make this very legal literature are wanted for every possible activity all the time, while nobody knows about the chemists.

We believe the era of chemistry will come about when chemists assume a great obligation to the general welfare; when they guide public opinion by expressing themselves with such facility that everyone can understand, while the substance of their discourse is of value to the public.

This is not to be brought about by a publicity agent or by propaganda. It will come as a result of constant and useful public service, and from the quality of public teaching that begets understanding and faith.

The Haber Process Pinned Down to Facts

ASIDE from its importance from the military standpoint and to the agricultural and fertilizer interests, the fixation of nitrogen by the Haber process has been of peculiar interest to the chemical industry since its commercialization in 1913, partly because it came to us so thoroughly labeled "Made in Germany." An air of mystery has been thrown around the details of the process and we have been regaled by stories of the Krupp superlathes which turn out tremendous seamless tubes of a marvelous new alloy for the German plants. Most of the mystery has been dispelled by the practical experience at Sheffield and today the Haber process is established on a commercial scale in America. Some residue of the original fascination, however, makes the subject of lively general interest, while those actively participating in the recent development eagerly seek reliable detailed information on different phases of the process.

It is therefore with an appreciation of their value that we call attention to the series of articles reporting the work of the Fixed Nitrogen Research Laboratory on the synthesis of ammonia which begins on another page of this issue. As an example of truly scientific research, these experiments might well be cited as a model. The laboratory has made a thorough study of the various ammonia catalysts and the general principles and problems involved in the synthesis. It is with the latter that the present series deals particularly. Among other problems, the increasing conversion with rising temperature, counteracted at a certain point by the increased rate of decomposition, presents an interesting study of great industrial importance. Again, the effect of pressure, temperature, rate of flow and catalyst poisons in the gas have been studied under conditions which made possible the accuracy of the research laboratory, yet which are unusually comparable to operating practice. It is well known that the chief difficulty in the Haber process has been the proper mechanical construction of the plant to withstand the action of the gases under the necessary high pressures. For this reason the detailed descriptions of the small-scale testing plants developed in these experiments will be of interest.

In the Haber process the gases are purified by catalysis and their combination is effected by catalysis. In another step which is on the verge of commercial application, the same ammonia is oxidized to nitric acid by catalysis. In view of these and a dozen other recent applications of the same phenomenon, we can but wonder how much more catalysis may do for us in the future. Certainly such research work appears unlimited in potential value.

Pig-Iron
Production in 1921

ON ACCOUNT of the physical disabilities of the iron industry in 1917, 1918 and 1920 we have the curious statistical fact that there has just been the longest interval in 43 years without a new record being made in a year's production of pig iron. The official report just issued shows a production in 1921 of 16,688,126 gross tons, last year having added a fifth to the years that have failed to break the record made in 1916, 39,434,797 tons. Not since the period 1874 to 1878 inclusive has there been a 5-year interval without a new record. Otherwise the comparison fails entirely, for after 1873, which was a panic year despite its record pig-iron production, there was practically no new construction for several years, while after 1916 there was new construction, the capacity not being available when iron was particularly wanted, in 1917, 1918 and 1920, because the railroads could not move sufficient fuel. Another difference is that the last year of this latest 5-year period, 1921, was by far the poorest year of the five, while in 1878 the iron industry was getting ready to make a new record.

Pig-iron production, in gross tons, from 1870 to 1921, inclusive, has been as follows:

1870.....	1,665,179	1916.....	39,434,797
1880.....	3,835,191	1917.....	38,621,216
1890.....	9,202,703	1918.....	39,054,644
1900.....	13,789,242	1919.....	31,015,364
1910.....	27,303,567	1920.....	36,925,987
1915.....	29,916,213	1921.....	16,688,126

On the basis of the 1916 production, with allowance for increases in capacity, the present capacity may be estimated at fully 45,000,000 tons, so that production in 1921 was about 38 per cent of capacity. There is room for argument that if iron and steel had been less scarce in 1920 the production in 1921 would have been larger. Production had been subject to three curtailing influences, the iron and steel strike begun Sept. 22, 1919, the bituminous coal strike and an insufficiency of transportation. Prices of steel and of manufactures of steel were forced to extremely high levels. At the beginning of 1921 there were high-priced stocks and the ultimate consumer was discouraged. To cite a commodity, usually exceptional, to test the rule, there were large stocks of canned food and other products in tin plate containers, the liquidation of which was very slow, the result being that tin plate, which usually holds up well in poor times, had a phenomenally poor year in 1921.

The iron industry has been particularly hard hit by the smallness of demand because there is a much smaller percentage than ever before of obsolete or obsolescent equipment. As the blast furnace has been improved from time to time, it is natural that a smaller proportion of the existing capacity is behind the times than used to be the case. Production, moreover, has tended to center more in certain districts, where the producers are more or less on an equality. Not infrequently in the past there have been times when the percentage of relatively high-cost furnaces was so great that the low-cost furnaces could make profits even though the total demand was much under the full capacity, whereas even now, when the rate of production is about 30 per cent greater than the average rate in 1921, there are many furnaces idle whose equipment and location cannot be criticized.

The layman is sometimes confused in attempting to harmonize the concept that steel is made from pig iron and some pig iron is used for making iron castings with the fact that in recent years our production of "steel" has exceeded the production of pig iron. Last year's production of steel ingots was about 19,500,000 tons, but in finishing the steel a loss of about 24 per cent occurs, to reach the material statistically reported as "finished rolled steel." The scrap involved, together with old material, is used in making steel, while for years the production of iron castings has been growing at a much slower pace than the production of steel.

Panic Prices
For Coal

EVERY factor now indicates a strike of serious proportions in the coal mines on the first of April. It is highly improbable that the Secretary of Labor, the Secretary of Commerce or any other government official can find any means for preventing this, despite the commendable efforts being made to that end. However, the situation is not by any means as black as painted by many; and there is no cause whatsoever for panic prices for coal.

Official estimates indicated that on the first of January of this year there was in stock in the hands of consumers about 47,500,000 tons of bituminous coal, which represented for these consumers on the average approximately 6 to 7 weeks' supply. During January production continued at least slightly above the rate of current consumption, and during February it is estimated that coal flowed into storage in considerable quantities every week. This condition will doubtless continue with even marked increase during the current month; and the end of the coal year will be reached with a certainty of average stocks throughout the country amounting to nearly 2 months' supply of bituminous coal. This is an exceptional, but very fortunate, condition for the end of a coal year, since normally at the beginning of spring the bituminous coal stocks of the country are reduced to a low figure as a matter of ordinary operating routine.

Another important factor must be taken into account also. This is the fact that the maximum probable interruption of coal production in union mines from strikes is not at all likely to cut off as much as half of the total production. Not only are there always some mines and some workers in various mines who do not go on strike, but also there are large sections of the bituminous coal territory which are operated on a non-union basis. It has been estimated on the basis of official figures that the maximum effect of the coal strike in union fields will probably not lower the production below six million tons per week. This is practically enough coal to run the country during the summer season with sub-normal business conditions prevailing as they now do. Certainly if six million tons per week is produced regularly during a strike period, this with existing stocks would care for the entire industrial demand of the country for many months.

It is worth while bearing these facts in mind. There will be great temptation to rush into the market and purchase coal as soon as the usual sources of supply are in any way interfered with. But this is wholly unnecessary, especially if carried to the extent of paying panic prices for the fuel. If American industry will "keep its feet on the ground," there will be no excuse for a runaway market.

Readers' Views and Comments

When Does an Employment Contract Terminate?

To the Editor of Chemical & Metallurgical Engineering

SIR:—I have read your editorial on "When Does an Employment Contract Terminate?" in the Feb. 22 number of CHEMICAL & METALLURGICAL ENGINEERING with a great deal of interest. I also read the opinion of the Chicago attorney. I agree with you absolutely, that technical men should be protected from every danger of blacklist, boycott or attempted curtailment of their usefulness to themselves or society through the operation of contracts signed while seeking employment. I also heartily agree with your stand that a court precedent should establish that a contract terminated in one particular is thereby terminated in every other. It seems to me that this is a matter of vital interest at the present time and that you are doing a noble work to bring the matter to the attention of the readers of your magazine.

W. M. CORSE.

Monel Metal Products Corp.,
Bayonne, N. J.

To the Editor of Chemical & Metallurgical Engineering

SIR:—Your editorial, "When Does an Employment Contract Terminate?" has very greatly interested me. It is a subject that has so many angles to it and is so dependent on the indeterminate personal equation that I hesitate to commit myself on the matter within the space of an ordinary communication.

Employment contracts exist in great variety, each corporation acting on the initiative of some one of its officers and in many cases without the scrutiny of an attorney with wide experience in drawing this class of contract. It is therefore impossible to discuss within a few words the broad general aspect of the individual contracts, for the real vital principle at stake varies so greatly in the form of statement, and language is here the key to the situation.

From the standpoint of *intent* I am quite certain that all reputable corporations have in mind the desire to prevent traffic in confidential information in their possession. Many such acquisitions have been purchased at considerable cost, and the purchaser is frequently obligated by contract not to convey the same to others. In other cases the specific information has been acquired by research and development at great cost, and the obligations of the executives to the stockholders require the guarding of the latter's interests. It is entirely fair and just to base a contract on such property and to place a restriction clause in an employment contract covering such property rights and their disposition.

Assuming the right of property in such matters, our problem becomes one of a fair disposition of the same. The fundamentals of all contracts are good faith and equity. Good faith in dealings between the corporation and the employee implies a detailed presentation of the character of the service to be rendered. This should be covered in great detail, and frequently be supplemented by additional contracts if necessary.

In the next instance, the contract should specifically provide for service as such, and in addition and separate from the first, restrictions on the disposition of discoveries, inventions, confidential information and future traffic in the latter items. The service clause should be for a definite period of time, a month, a year, or longer. Provision should be made for its termination because of unsatisfactory service after due notice, otherwise if the whole burden incident to unsatisfactory service rests on the employer, employment will become too difficult in general. General business depression should not be a terminating factor, any more than it is on raw material contracts. The weakness lies in the machinery to adjust such differences as might arise in connection with the service clause, this at present being more burdensome to the employee than to the employer.

The restrictive clauses are more complicated. Real property is conveyed with restrictions as to its use. These restrictions are limited as to expiration date; in the case of patented articles to the date of expiration of the patents. The restrictive clause in the employment contract should similarly be limited as to expiration. Now it is pretty well recognized that chemical processes, for example, become obsolete in a comparatively few years. I believe that so-called secret processes rarely persist in their original form for 5 years. The equitable form of contract would therefore terminate the restrictive clause in a reasonable and comparatively short time. This period has nothing to do with the period of service, and their termination would not be simultaneous.

The restrictive clauses should be explicit to be fair. I am not in sympathy with the attempts frequently made to broaden the scope of such clauses to cover everything. No attempt should be made to cover any more than the specific activities directly concerned. Provision should be made for supplementary contracts if necessary to cover advances in the state of the art. With good faith shown in the incorporation of such clauses in the contract, there can arise no criticism on the part of the employee, for no individual meriting at any time such confidence as to become a party to such contract can be so narrow in his adaptability as not to find means of livelihood outside the narrow restricted field intended to be covered. I should even very closely scrutinize a plea of hardship.

I therefore believe that a perfectly fair employment contract can be drawn which will protect the employer in his just intent as discussed above, and future criticism on the part of the employee forces on the latter the burden of proof that he signed such in good faith. Compensation under such contracts is generally above the normal for the same class of general service, and the extra compensation must be looked upon as a surplus against the imposed restricted future activities.

The real remedy for abuses, if such exist, is to make unnecessary this form of contract. This can be done by eliminating the necessity of maintaining processes secret, through a comprehensive and adequate patent law whereby the granting of a patent assumes novelty, without the burden of adjudicating the same through endless litigation.

Raising of the ethics of the profession would go a

long way, for I believe that if all members of the chemical profession are governed by the highest motives of loyalty and fair dealing, there will be no misunderstanding concerning employment contracts on the part of either the employer or the employee.

These two remedies are such remote possibilities that a more practicable method of immediate application would be to have our major engineering societies take up the matter of a uniform employment contract, providing such has not already been done, and under the guidance of proper legal assistance and with the cooperation of representative employers in as many fields of activities as is practicable, I am certain an equitable form of contract could be drawn. W. S. LANDIS.

New York City.

To the Editor of Chemical & Metallurgical Engineering

SIR:—I have read with interest your editorial in the Feb. 22 issue of CHEMICAL & METALLURGICAL ENGINEERING, also the comment as formulated by Wellington Gustin.

It has always appeared to me that arrangements made between technical men and financial interests have been too vague and often leave a confusing impression. A contract drawn up between a chemical engineer and his employer should never include terms which forbid for all time the technical man in question carrying out other lines of work of similar nature, should the company find it necessary to discontinue his services. No man should agree to limit his value on this earth by any such arrangement.

I am firmly convinced, however, that the manufacturer should have adequate protection, having in mind particularly an extremely small percentage of technical men who purposely might seek employment in a certain industry for purely dishonorable purposes. I think it entirely just and legal that a contract include terms which for a reasonable time prohibit the technical investigator either publishing or applying for patents on subjects which are directly concerned with work within the industry.

In other words, I think there should be established a reasonable time interval during which the manufacturer may protect his own interests by suitable patent publications. This could usually be done within a period of not greater than 2 years. It is also fair to assume that a technical man in a responsible position will disclose important information to his employer and agree to apply for patents and assign such patents to the company in question. Such an agreement could also appear in the contract terms. I believe that arrangements of this type would encourage disclosures of progress through patent publication, and would discourage the accumulation of a rather large amount of technical information which is now zealously guarded by so-called secret processes.

A reasonable time limit within which the technical investigator would be committed to public inactivity so far as the particular work in question is concerned would surely offer adequate protection in most cases which might arise. It would also provide an opportunity for the investigator to continue work along lines in which he may have become interested and which may result in findings of extreme importance. In all events, special cases would always be open to litigation and could be judged according to precedent and equity.

To the Editor of Chemical & Metallurgical Engineering

SIR:—In regard to the editorial, "When Does an Employment Contract Terminate?" and also the comment of Wellington Gustin under the same title, the following may put into bas-relief certain phases of the subject under discussion which have been so well covered by those articles.

The employer is almost the exact antithesis of the employee and his functions are almost exact antitheses of the functions of the employee. The differences may be summed up tersely as follows:

The employer deals with humanity, while the employee deals with scientific knowledge, ingenuity and materials. It is the employer's business to accomplish as much as he can by utilizing humanity, and his success is measured by the ability which he displays in utilizing humanity. In the same way the employee's success depends on the use he makes of his scientific knowledge, ingenuity and materials.

Now, while the employer delves into the storehouse of knowledge and materials held by the employee, the employee has not as a rule thought it necessary to delve into that knowledge of human nature upon which in a large degree business depends. And right here is where the employee loses out. It thus happens that the employer is in a position to work upon the credulity of the employee who has not taken the trouble to inform himself of his rights and privileges. The courts have many times decided that the employer who furnishes materials and defrays all expenses of fruitful research thereby acquires a shop right in the invention, but that the inventor is entitled to the patent rights unless otherwise assigned. On the other hand, if the inventor makes his invention at his own expense and in his own time, the employer has no claim on even a shop right in such an invention. This knowledge is known by the employer, but is not usually known in time by the employee if known at all. The employer uses such knowledge as this to insert into the contract of employment that the employee shall assign all inventions during his period of employment to his employer. In a sense this is coercion, for a man in face of present necessities will sign away any rights for the future which he regards as fanciful, illusive or only existent in the fancies of his employer.

The employee furthermore does not as a rule take advantage of such business opportunities as are open to him. He not only does not do this, but he deliberately puts his neck in a noose and then complains if the holder of the noose is tempted to pull it tighter than he thinks comfortable.

The business man has no hesitation in advertising his goods and stock in trade. He is not held back by any false modesty from claiming that he and he alone is giving more value to his customer than any one else. This is so much the custom that such action is regarded as a matter of course.

The employee may be a shining light and yet may have it hidden within the walls of a factory so that others have no knowledge that such a light exists. You certainly cannot blame an employer having a gold mine for not advertising it when such advertisement might result in the payment of increased royalty or might lose for him the gold mine altogether.

Now having shown that the employer has no object in advertising his employee, it necessarily follows that the employee will remain unadvertised unless he is

advertised by one who will benefit by such advertisement and that one is himself and no other.

The employee's ability, knowledge and accomplishments are his stock in trade, and it is up to him to create a demand for his wares. While modesty is an admirable quality in polite circles, it has no place in business, especially that false modesty which enforces a sort of peonage on the employee. The law of supply and demand is as applicable to labor as to materials and the employee should know this and create a demand for his services by some sort of advertisement. When there is a large demand for his services, then the employee will receive compensation commensurate to his worth and the demand.

Nor is there a lack of opportunities for judicious and dignified advertising. The technical journals are open to a man who has something worth while to say and the technical societies are anxious to obtain the co-operation of a man of sound ideas who has back of him the record of accomplishment. By this I do not mean that the employee should divulge any of his employer's secrets while in his employ, for there is no justification whatsoever of such a proceeding. But the employee obtains a vast amount of knowledge which may be correlated in new ways, giving valuable scientific results. These usually are his own property and part of his stock in trade. These things he can use himself or give to someone else to use for him in acquiring the sought-for reputation.

While the obligations of the employee to the employer are easily defined, the obligations of this same man to his former employer when he is no longer the employee are scarcely definable at all, inasmuch as these are governed almost entirely by the original contracts and by the ethics of the particular case.

Contract or no contract, the employee owes complete loyalty to his employer. Mutual confidence, trust and respect are the foundation stones for both parties.

I believe that applies in the great majority of cases and I do not believe that more than 1 or 2 per cent of a scientific staff deliberately obtain employment for the purpose of obtaining secrets.

Now having touched on the above principles, let us get a little closer to the subject in question.

In making a contract the employer has a right to safeguard his existing property, including secret processes, if he can. The only protection he has, however, is so to adjust conditions that the employee has a mutual interest in the secret. He can bring suit for money damage against the employee, but this right is weakened by lack of money responsibility of the employee. In case of enticement he can bring suit against the offending corporation, but enticement would be difficult to prove in cases where the employer let his staff go whether because of business depression or some other reason. In exercising his right of discharge, he made a choice in which he presumably considered the problem of dissipation of the firm's stock of knowledge and his chances before the law court. In exercising his right of discharge, self-interest will compel him to act in such a manner that the firm shall suffer the least and the axe will fall upon him who can least easily obtain a job in a competing concern. And this is the man who neglected to make hay while the sun was shining.

The reason is obvious, for the man with a wide reputation can in a consulting capacity disseminate this knowledge far and wide, thus making competition keener, with the result that it will be cheaper to keep him on the payroll, even if there is nothing for him to do, than cast him adrift where he can do untold harm. On the contrary, the man of a retiring disposition is scarcely to be feared, for he has already shown that he has the lack of business initiative and such initiative cannot be developed on the spur of the moment. In an equity case the complainant must come into court with clean hands. The issues could be thoroughly befogged in an equity court. Not only would this be the case, but the facts concerning the secret process would have to be divulged, in which case the process is no longer secret and the appeal to equity has defeated its own purpose.

It seems to be a fact that employment contracts really have but little value for the employing party unless made with persons having moral responsibility, because the financial responsibility usually isn't there.

There is one phase of this question which should be carefully considered. Is it consistent with public policy that a man should be required to sign away the patent rights of something which he has not yet invented and knows not the value? Should not the employer be forbidden by law to insert such a clause into any contract with any employee? As it is, this is a sort of coercion or peonage in that the employer will always give the job to him who thus signs away his rights, not knowing their value. Is it not consistent with public policy that such insertions of a coercive nature be declared null and void? When such an invention has been made, the employer will usually have a shop right and will have the advantage of knowing its full value better than any outsider. He can then make terms with the inventor and such terms being made in light of full knowledge will have more of the elements of justice.

Another phase of this matter seems at least worthy of mention. When an employer hires the employee in such a capacity where it is known that he will obtain secrets and in all probability make valuable discoveries and where the employer assumes the financial burden of all the experimental work, the employer has certainly some rights. It is scarcely just to expect him to stand the financial losses indissolubly connected with those experiments which turn out failures, while the employee reaps all the benefits of those experiments which turn out to be successes. Such a condition would be against public policy, as it would mean the end of research and consequently tend to check progress.

I am inclined to agree with the general position of the editorial that it would be against public interest to make enforceable a contract binding a man not to use previously acquired knowledge or training.

The operator of a secret process has always been presumed to know that he has a perishable article and that the risks are all his own; the patent law itself is a recognition of this.

And, finally, we must not lose sight of the fundamental truth which has governed and always will govern the actions of humanity. In the final working out of the economic law irrespective of what laws are now on or may be put on the statute book, self-interest is the all-controlling factor. Where initiative, foresightedness, energy, prudence and due attention to self-interest will bring their reward, the lack of them will as certainly bring embarrassment and want in time of stress.

The ultimate solution depends upon the employee's ability to make it contrary to the self-interest of the employer to discharge him.

HUGH K. MOORE.

Brown Co., Berlin, N. H.

British Chemical Industries

FROM OUR LONDON CORRESPONDENT

LONDON, Feb. 17, 1922.

THE trend of business in January and particularly in the first two months of the year is usually a reliable index to the ensuing year's prospects, and on the whole the outlook is considered favorable. The annual reports and the speeches of the chairmen of the great banking groups have, it is thought, summed up the position with exceptional lucidity and in accordance with informed public opinion. Briefly, strict economy and thrift are to be the watchwords for all, with a definite hope of improving trade and stability, particularly on export account. The reduced bank rate and some relief in the pressure of continental competition, together with easier monetary conditions, have already made themselves felt and stocks in many commodities are appreciably lighter. Buyers in consequence are becoming uneasy and covering their requirements over a longer period instead of continuing the hand-to-mouth policy which served them so well during the recent period of uncertainty and stringency. It is still too early to say anything definite as to the effect of recent legislation, but the safeguarding of industries act has certainly stimulated the fine chemical trade and saved it from complete stagnation. The sulphuric acid and fertilizer trades are reviving, sulphate of ammonia being in demand owing to the peculiar conditions prevailing in America, and basic slag being also in good inquiry. Failures in delivery from continental sources have caused prices to harden in several cases and with a miniature revival in the coal, steel and textile trades, the prospects are distinctly encouraging.

GAS COMPANIES DEFEND THE USE OF WATER GAS

The scare raised in the daily press in connection with the presence of carbon monoxide in coal gas due to the admixture of water gas has roused widespread interest and comment. It so happens that a few cases of carbon monoxide poisoning due to escapes of gas occurred in the provinces and attention was promptly called to the large number of parallel cases which were noted at one time in the United States. The agitation has now practically died down, but not before an order was made under the gas regulation act regulating the amount of carbon monoxide which may be supplied in domestic gas unless the gas supplied has the distinctive odor of coal gas. The chairmen of the two leading gas supply undertakings in London defended the use of water gas, although the South Metropolitan Gas Co. has not so far used it as a diluent.

CALCIUM CARBIDE HELD TO BE AN INORGANIC CHEMICAL

The result of this case was almost a foregone conclusion, but the hearing under the safeguarding of industries act was useful in clearing the ground for other cases. The referee in his decision stated that he would adopt the principle that no article should be included in the dutiable list if there is any reasonable doubt that it should be excluded, and that the burden of proof is on the complainants; that in regard to "fine chemicals" he would adopt the rule: Has it been proved that in the opinion of the bulk of chemists this or that is a fine chemical? But he would accept this only if there was a technical definition. What happened in the carbide case was that an equal number of eminent experts on either side were willing to classify calcium carbide as organic or inorganic, but the balance of evidence from textbooks and official publications inclined to its classification as an inorganic chemical.

CONFLICTING EVIDENCE IN THE CREAM OF TARTAR AND TARTARIC ACID CASE

This case, in which citric acid is also included, will turn on the point whether the term "fine chemical" has a well-understood commercial meaning and if so, what is the accepted view of the trade. The result so far has been a plethora of definitions in the technical press, not one of which has yet been applicable to every instance that can be cited. We have here products which can be obtained in commercial quantities with a high degree of purity both by skilled and by unskilled methods of manufacture according to the locality in which such manufacture is carried on. French firms appear to be manufacturing crude products without skilled supervision and control, while in this country, which draws its raw material from a number of sources, scientific control is essential, especially for the manufacture of B. P. products. The process as carried out in France would, according to one definition, enable the product to be classified as a heavy chemical, whereas in this country tartaric acid would, under the same definition, be a fine chemical. The view of the trade seems to be that, except for B. P. products, the large quantities sold and trade usage will enable the crude products to be imported free of duty, while discriminating against B. P. products.

ALBY CARBIDE CO. GOES INTO LIQUIDATION

This company has been in difficulties for some time, mainly on account of the unfavorable contracts into which it had entered and owing to its failure to pay for its power rent, the plant having closed down. The Tyssefaldene Power Co., in which the Barton group holds a controlling interest, has bought the whole plant, valued at about $1,500,000, for about $7,000, the rights held by the power company rendering it impossible for others to bid at the foreclosure sale. In consequence, Alby shares are now valueless and the company will be wound up. The recent carbide decision lends additional interest to the case, but as regards the future operations of Cumberland Coal, Power & Chemicals, Ltd., in Norway, the position is still very uncertain, as so far the capital required for the development of the Claude process does not appear to have been forthcoming. Mr. Barton was originally closely connected with the Alby Carbide Co.

GENERAL NOTES

The British Dyestuffs Corporation has failed to pay a dividend on its preference shares and although markets are improving, the future does not seem to be very bright. This also applies to the British Cellulose Co., whose shares have fallen still further, partly on account of the decisions in the carbide case. An interesting monograph on synthetic phenol manufacture during the war has been published by the Department of Scientific and Industrial Research, and is worth studying for its chemical engineering interest alone. Further progress is being made in the standardization of chemical plant, both by the British Engineering Standards Association and by the Association of British Chemical Plant Manufacturers, the latter having made a beginning by publishing designs for standard jacketed pans.

American Ceramic Society, Annual Meeting

Report of Twenty-Fourth Annual Meeting, Held at St. Louis—Important Papers Presented Before the Meetings of the Seven Industrial Divisions: Art, Enamels, Glass, Heavy Clay Products, Refractories, Terra Cotta, White Wares

IT was scarcely necessary for Mayor Kiehl of St. Louis to utter formal words of welcome to the members of the American Ceramic Society, gathered at the Hotel Statler for their twenty-fourth annual meeting, Feb. 27 to March 3. The almost continuous rows of brick structures throughout the city evidenced appreciation of what ceramic skill has done to advance human comfort and happiness. Then, too, the sight of the great refractories plants, the fireclay mines even within the city limits and the knowledge that the whole city rested on clay deposits—what more was needed by way of welcome! Nevertheless Mayor Kiehl was there in person to extend a hearty greeting.

Throughout the meeting a state of constant, yet ordered, activity was maintained through the untiring efforts of the local committee. The complete absence of friction in carrying out the schedule indicated careful preparation. The smoker and entertainment on Monday, the informal banquet the following evening and the plant visits on Thursday and Friday were potent factors in maintaining that spirit of fellowship for which the Society is noted.

Through the efforts of the Art Division an exhibition of ceramic wares was held in conjunction with the meeting. The exhibits covered the entire range of ceramic products—from the highly artistic and beautiful work of Mr. and Mrs. Rhead, Prof. Binns, Miss Farren and others to the more commonplace sanitary ware, chemical stoneware, electrical porcelain, refractories, etc.

General Sessions

Forrest K. Pence's presidential address on "Progress and Policy" brought out the necessity for outlining a general policy for the Society in its enlarged field, in order to render the most service possible, both within and outside of the organization. As examples of service needed, Mr. Pence mentioned the publication of a ceramic handbook and monographs on certain industries.

Conditions have changed since the Society was founded and a stage has been reached where the industries are beginning to see the economic reason for cooperative research. The industries must finance this group research, but it is the function of the Society to encourage such work and to provide a publication medium and a forum for discussion.

Reduction of Varieties

E. W. McCullough, manager of the Fabricated Production Department, Chamber of Commerce of the U. S. A., outlined the work which is being done to eliminate excess varieties of commodities. For machine-made products, small variety and large output are essential to low cost. In many lines, our salvation has been and will continue to be mass production, but mass production is not possible if varieties are multiplied to meet the whims of overambitious sales organizations. An example was given of an iron and steel firm which discovered that its catalog was increasing out of all proportion to the profits. Upon studying the 17,000 products listed, it was found that only 614 were profitable.

Prof. C. W. Parmelee proposed a new classification of clays. Prof. E. W. Washburn and Elmer N. Bunting demonstrated and explained their porosimeter for determining porosity by the method of gas expansion. Deformation studies of the silicates and aluminates of the alkali metals were reported by B. A. Rice. Investigation of the systems K_2O-Al_2O_3-SiO_2 and Na_2O-Al_2O_3-SiO_2 indicates that sodium and potassium may be interchanged for their fluxing value.

From X-ray spectra, Prof. E. W. Washburn and Louis Navias conclude that raw chalcedony and raw flint have the structure of quartz, while after calcining the structure of both resembles cristobalite. Both are probably colloidal.

Dr. Kurd H. Endell, professor of ceramic engineering at Charlottenburg, extended an invitation to the members to meet with the newly organized German ceramic society in June.

In a paper on "Reduction of Industrial Wastes," Dwight T. Farnham reviewed the important work done along these lines.

Fuel Oil Systems

Important factors to be considered in installing and operating fuel oil systems were discussed by James D. Lalor. He recommended that storage tanks be placed in concrete pits rather than buried directly in the earth, since a leak in the latter case might cause serious trouble before it was detected.

R. M. Howe showed that the furnace gas pressure has a very decided effect upon heat transmission through furnace walls. A 10½-in. tile was set in the door of a surface combustion furnace and temperatures were measured in this tile 1, 2, 3 and 4 in. back from the hot side. Under a draft of —0.30 in. of water the temperature drop across the 4 in. was from 1,340 to 500 deg. C. With a draft of +0.05 in. the drop was 1,340 to 750 deg. C.; with forced draft (+1.00 in.) from 1,340 to 850 deg. C. Evidently the penetration of hot gases is a factor which must be considered.

Election of Officers

Officers elected were: President, F. H. Riddle; vice-president, Dr. E. Ward Tillotson; secretary, Ross C. Purdy; treasurer, R. K. Hursh.

Mr. Riddle is director of research for the Champion Porcelain Co., Detroit, Mich. This was formerly the Jeffery-Dewitt Co., but is now a subsidiary of the Champion Spark Plug Co. During the war Mr. Riddle was associated with A. V. Bleininger at the Bureau of Standards and worked on the development of special high-temperature porcelains, including spark plugs for airplanes, also on the development of the casting of porcelain glass pots for optical glass manufacture.

It was decided to transfer all editorial work to the secretary's office and to make the secretary editor of the

F. H. RIDDLE
President, American Ceramic Society.

journal for the coming year. Pittsburgh was chosen for the twenty-fifth annual meeting in 1923. The summer meeting this year will be held in Montreal and vicinity.

Refractories Division

Fireclay Deposits

Merely as a matter of record Paul E. Cox presented his paper confirming previous reports on the non-existence of satisfactory fireclay deposits in Iowa. There were some, however, which he thought might serve for cheap brick for the crowns of kilns. Prof. C. W. Parmelee then described in some detail the more important deposits of fireclays in Illinois.

Influence of Grind and Firing Temperature on Properties of Silica Brick

Some very interesting tables showing the influence of grind and of firing temperature on the properties of silica brick were presented by R. M. Howe. The time of grind was 10, 15 and 20 minutes and the firing temperatures from cone 11 to cone 19. The property studied in one set of tables was the modulus of rupture. In the 10-minute grind the modulus of rupture varied from 295 to 531 when the burn varied from cone 11 to 19, the average of 42 determinations being 440. Corresponding figures for the other grinds are 15 minutes, 285-618, average 446; 20 minutes, 330-694, average, 499. Averages of twenty-one determinations on the effect of temperature are:

Cone	11	14–15	15–16	17	18	19
Modulus of rupture	303	368	444	572	533	614

Thus it will be seen that, judged from the averages, the firing temperature has a greater influence on the modulus of rupture than the time of grind.

The specific gravity was found to decrease from 2.50 to 2.30 in going from cone 11 to cone 19, while the grind did not have much effect on this property. Porosity increased slightly with time of grind.

Hydrates of Alumina

Studies of the composition and properties of diaspore, bauxite and gibbsite have led R. M. Howe and R. F. Ferguson to the conclusion that diaspore is the monohydrate of alumina, gibbsite the trihydrate and that bauxite is a mixture of the two. In the discussion which followed I. A. Krusen referred to the plant of the American Bauxite Co. at Bauxite, Ark. Here the bauxite occurs in blankets from 3 to 25 ft. thick and the stripping required varies from 10 to 60 ft. The overburden is removed by steam shovels. Most deposits are less than 10 acres in extent. The ore is crushed to 1-1½ in. in gyratory crushers and transferred to bins which feed ten rotary kilns, formerly fired with natural gas but now using powdered coal. The capacity is 2,500 tons a day, most of it going to the Aluminum Co. of America, although some is shipped to the Norton Co. At one time the General Chemical Co. took a great deal of low-grade ore for the manufacture of alum.

Testing of Silica Brick

Prof. K. Endell described briefly the methods used in Germany for testing silica brick.

An attempt was made by E. N. McGee to develop a relationship between the hot and cold modulus of rupture for silica brick, with the idea that the valuable indications given by the hot modulus might be calculated from the more easily determined cold modulus. Before any definite conclusion can be reached it will be necessary to test other brands and use more samples. The point at which the silica brick is weakest should also be determined.

Ladle Brick

In a paper on ladle brick, D. A. Moulton stated that in this country this variety of brick is made from No. 1 and No. 2 fireclay and contains: SiO_2, 60-67 per cent; Al_2O_3, 20-24 per cent; Fe_2O_3 1-3.5 per cent; CaO less than 0.3 per cent; Na_2O and K_2O, 3.5 per cent. The brick are made either by the stiff mud or dry press process, the latter giving a superior product. The brick will usually withstand eleven or twelve heats. Special testing methods are required, as the tentative and standard methods are not applicable.

In discussion, A. F. Greaves-Walker, chairman of the division, emphasized the importance of ladle brick. They are used not only in the large copper and steel plants, but even in medium-sized foundries, especially where electric furnaces are used. He also referred to the secrecy which has surrounded the manufacture of ladle brick.

Heat Conductivity Data

Data on heat conductivity of the different commercial refractories are somewhat confusing owing to the fact that the conditions of preparation or test are not comparable with industrial conditions. In presenting this subject, Prof. Arthur S. Watts emphasized the difference between heat conductivity as usually measured and heat transfer, which is what is really required for engineering work. The former neglects the skin or surface effect, which has a very appreciable influence on the rate of heat transfer from a point just in contact with

one surface to a similar point on the other side of the refractory.

Prof. Watts found that the literature on the subject was practically limited to the following: Wologdine and Queneau, *Electrochemical & Metallurgical Industry*, September and October, 1909; "The Thermal Conductivity of Refractory Materials," by G. Dougill, H. J. Hodsman and J. W. Cobb, *J. Soc. Chem. Ind.*, vol. 34, p. 465, May 15, 1915; "Thermal Conductivity of Refractory Brick," W. Van Rinsum, *Science Abstracts*, "B," Jan. 30, 1920, p. 18, also *Chemical Abstracts*, vol. 14, p. 1420, May 10, 1920. The scarcity of data and the fact that some of the available data are open to criticism prompted Prof. Watts to make an investigation to determine relative values, at least, under the following conditions:

(*a*) The test specimens are normal samples of commercial ware on which the burning temperature is known.

(*b*) The test specimens are of the same thickness so far as possible. All are exactly as made and burned except the magnesite brick, which was tested in the original thickness and later cut down by grinding off one face, thus reducing it to the same thickness as the others.

(*c*) The test furnace is an electrically heated furnace capable of maintaining an approximately constant temperature for a period of 8 to 10 hours.

(*d*) Each test is continued until a state of practical equilibrium exists. To insure this, the test was continued until the temperature change on either side of the test specimen did not exceed 5 deg. per hour.

(*e*) The conditions of test were maintained constant as regards drafts, the furnace being so located that the exposed face of the test specimen is cooled only by normal radiation.

(*f*) The same insulating arrangement is provided for all specimens. This consists of kieselguhr cleats cut to fit and extending ¾ in. over the edges of the brick, thus preventing radiation of heat along the line of contact between the furnace and the test specimen.

(*g*) Standardized copper-constantan thermocouples are used and the voltage measurements determined by means of a Leeds & Northrup potentiometer.

In order to make the results comparable, temperature gradients were determined by subtracting the temperature of the cold side of the test specimen from that on the hot side and dividing by the diameter of the test specimen expressed in centimeters. Hard steel was chosen as unity, giving the following results:

Specimen	Diameter, Cm.	Temperature Gradient, Deg. C.	Relative Transfer of Heat
Normal fireclay	3.1	174	0.448
High SiO_2 fireclay	3.1	170	0.459
Bauxite	3.1	163	0.478
Silica	3.3	152	0.513
Magnesia	4.0	125	0.624
Magnesia	3.1	135	0.578
Chromium	3.15	108	0.722
Hard steel	3.0	78	1.000

The above values are merely relative and must be so considered. The wisdom of using steel as unity is open to question, since its absorption and emission properties are widely different from those of the refractories. The relative heat conductivity may or may not be proportional to the temperature gradient of the different refractories. If it is proportional, then the relative values of the refractories as heat insulators would be:

Fireclay refractory	1.00
High-silica clay refractory	0.974
Bauxite refractory	0.937
Silica refractory	0.873
Magnesia refractory	0.776
Chromium refractory	0.621

DR. E. WARD TILLOTSON
Vice-President, American Ceramic Society

It was pointed out by the speaker that the mean temperature throughout these determinations was only about 600 deg. C., which is below operating conditions for these refractories, and that consequently the work should be extended to higher temperatures.

In discussion, Mr. Greaves-Walker said that results such as these were of the greatest importance at the present time. With powdered coal, oil and gas, using air under pressure, temperatures of 2,800 to 3,100 deg. C. are becoming quite common. In order to maintain these temperatures with refractories now in use the walls must be made more conductive. Thus reverberatory walls which used to be 24 in. thick have been reduced to 9-12 in. in order to get rid of the heat. It is inefficient so far as heat goes, but the desired reaction is obtained without sacrificing the refractories. The same is true of high-powered boilers when forced much above their normal rating.

Discussion of Questions

Perhaps the most valuable part of this meeting was the discussion of a number of questions which had been asked by members and printed in the program so as to give time for consideration.

The problem of calcining clay was considered from many angles, including the relative merits of rotary kilns, downdraft kilns and other types. A. B. Christopher outlined the method used by the Evens & Howard Firebrick Co. The clay is fed from boxcars on a trestle directly into a shaft kiln having a capacity of three boxcars. The clay must be in chunks and not frozen. The kiln is 28-30 ft. high and 14 ft. diameter, with six fireboxes. To burn 140 to 150 tons of coal to a red heat requires under the most favorable conditions

18 tons of coal, although this may occasionally run up to 50 tons.

Silica, magnesite and chromium brick manufacturers are interested in the use of railroad tunnel kilns. Philip Dressler described a new type of tunnel kiln which has been designed to meet the requirements. Silica brick requires a long time to burn, so that in order to get capacity the cross-section of the kiln must be large. Then, however, it is difficult to control the flow of gas uniformly, as most of it tends to follow the crown. This led to the suggestion of passing the gases across the kiln instead of lengthwise and a kiln has been designed having 12-ft. sections each equipped with regenerators. Two tracks will be used, the cars passing in opposite directions to give efficient heat exchange. Prof. Endell remarked that a kiln using the principle was started 2 months ago in Germany for burning insulators to cone 16.

The possibility of machine-made silica brick also received considerable attention. It was brought out that some time ago the silica brick manufacturers got together in the Refractories Machinery Corporation and in conjunction with Prof. Norton of M.I.T. built and installed two silica brick machines. Only one actually worked and that gave no end of trouble, particularly in getting the brick out of the mold. The machine was finally scrapped. Another is being designed, however, which more nearly reproduces the operations of hand-molding and promises to be more successful.

Dr. F. A. Harvey called attention to the fact that while there were curves showing the thermal expansion and transition points for pure silica, there was none which could be applied directly to green silica brick being burned.

Glass Division

Substitutes for Natural Gas

Under the title "The Passing of King Methane," S. R. Scholes discussed the situation brought about by the rapid diminution in the supply of natural gas, which is conceded to be the ideal fuel for glass manufacture. The question of substitute was taken up, producer gas, byproduct coke-oven gas, and fuel oil being considered.

Mr. Scholes also deplored the lack of sufficient data on design in tank construction, and this point was brought up in the discussion which followed by H. L. Dickson, who pointed out that this condition was quite natural, since it is only recently that technical men have been employed in glass works. Full credit should be given the technical men for perhaps the major portion of the advances in tank construction.

Zirconium Silicate Brick in Small Glass Tank

H. T. Bellamy discussed the use of zirconium silicate brick in the crown of a small glass tank with surface combustion burners, in which a silica crown had eroded and spalled due to frequent shut-downs. Zirconium silicate gave none of these troubles. This is probably the first use in a glass tank of this new material, which, although twice as heavy as silica, and costly, has interesting possibilities.

Officers

Officers for the division were elected as follows: Chairman, Dr. J. C. Hostetter; vice-chairman, A. R. Payne; secretary, A. E. Williams; councilors, Dr. H. W. Hess and J. W. Wright.

Enamels Division

The meeting of the Enamels Division opened with a paper by L. A. Adams describing a brushing and striping machine, which eliminates the use of hand brushing in wiping the edges of stove parts and similar pieces.

W. C. Lindemann discussed the use of the Mott sand table, and J. F. Bardush gave the results of some experimental work on the adaptation of the Meurer apparatus for spraying and applying melted enamel.

Electric Furnaces for Enamels

Studies designed to determine whether the reducing conditions in a carbon resistance furnace would be detrimental to enamel smelted in a furnace of this type were outlined by E. E. Geisinger. The results obtained were satisfactory, although no marked improvement was noted.

Recent installations of electric furnaces in bathtub, kitchen ware, sign and watch dial enameling plants were described by James Carpenter.

Air-Cooled Enamels

Stefan Wiester gave the general results of studies on the use of enamels chilled from the smelter by compressed air instead of being water-quenched. An interesting feature of this work is the appearance of the enamel. Due to the fine division of the glass, it is fluffy and light, and looks like a mass of cotton.

Effect of Fineness of Grind on Opacity of White Enamels

Finding it difficult to obtain uniform opacity in two-coat kitchen ware having one ground coat and one white coat, B. T. Sweely and E. S. Prince investigated the influence of the fineness of grind on opacity and found this factor to be a most important one, since opacity is a refraction phenomenon. It was not found possible to control the fineness by the time of milling, since the latter is influenced by the amount of moisture in the mill charge.

Mr. Sweely also read a paper on "Relation of Composition and Resistance to Thermal Shock," in which he called attention to the fact that during sudden temperature changes the outer coat of an enamel may respond before the change has been transmitted to the inner coat. Increasing the coefficient of expansion of the ground coat was suggested so that ground and cover would expand and contract more nearly at the same rate.

Observations on Fish-Scaling of Ground Coat

Interesting observations on fish-scaling of ground coat enamels were made by B. T. Sweely. Various articles enameled on both sides were treated with an acid so that the enamel was entirely removed from one side. According to the author, this should throw compressive strain into the enamel on the other side. If fish-scaling is due to compressive strains in the enamel due to difference in the coefficients of expansion of the enamel and steel, fish-scaling should result in the cases under observation. This was definitely shown in a number of specimens which had not previously shown fish-scaling, although they had been in stock for a number of months prior to the test. Furthermore, ware coated with an enamel apparently in tension (since crazing occurred) did not show fish-scaling when submitted to the acid treatment. In discussion, it was

brought out that other investigators had produced fish-scaling in pieces coated on only one side upon treatment of the other with acid. It would seem that penetration of the ware by hydrogen or even acid might be as important in this case as the release of compressive strain.

Microscopic Studies of Enamel Reactions

A miscroscopic study of ground coat and cover coat enamel reactions, by E. E. Geisinger, showed the effect of various enamel ingredients on the structure and also the effect of under-firing, over-firing and correct firing. Certain oxides showed evidence of reduction in that there was considerable bubbling in the enamel. In these cases the adherence was good. This apparently explains why cobalt oxide and other oxides are beneficial in ground coats. Mr. Geisinger illustrated his talk with a series of remarkable microphotographs of vertical cross-sections of enamels. In all cases the line of demarcation between the various layers was distinct.

Wet Process Enamels for Cast Iron

R. R. Danielson and H. P. Reinecker reported an extended investigation by the Bureau of Standards on wet process enamels for cast iron. The effect of various refractories as mill additions and the effect of variation in ground and cover coats were given. It was shown that large additions of flint, feldspar or clay to ground coats produced unsatisfactory enamels in that it resulted in poor adherence to the casting. It was found that comparatively large amounts of lead oxide in ground coats of this type wre not detrimental. Excess boric acid caused crawling in both ground coat and cover enamel. Cryolite had a tendency to cause the same trouble in the cover enamel. Large amounts of Na_2O were detrimental in that pin-holing was increased considerably.

Modified Molecular Formula

The present molecular formula used by technical men for glaze and enamel calculations is capable of misinterpretation. J. E. Hansen suggested a modification which should relieve the situation and furnish a better basis for the comparison of enamel formulas. In this modified formula an attempt is made to show the mineralogical form in which the fluorides are introduced.

Composition of Cast Iron for Enameling

M. E. Manson called attention to the fact that the physical condition of cast iron was more important than the chemical composition. Thus cast iron made from Northern pig tends to develop blistering in th enamel, while very satisfactory enameling results can be obtained on cast iron from Southern pig iron.

The committee on research has in mind the collection from cast-iron enamelers of representative samples of iron giving satisfactory and unsatisfactory results in enameling in order to make a systematic study of their physical and chemical properties in relation to enameling. This work will be under the direction of R. R. Danielson of the Bureau of Standards, Washington.

Fish-Scaling

The committee on research and development reported the results of co-operative work in the preparation of steels based upon the conclusions reached in the Bureau of Mines work on fish-scaling. Tests on about 2,000 sheets of steel prepared by the American Sheet & Tinplate Co. and enameled in three kitchenware plants were described. The sheets were cold-rolled to various extents and it was found that the tendency to fish-scale was reduced up to about four passes. Further passing did not prove beneficial. This apparently confirms the conclusions of the Bureau of Standards based upon laboratory work. The final report will be included with the bureau's work in a Technologic Paper on "Causes and Control of Fish-Scaling."

Heat-Resisting Racks

Preliminary laboratory tests on various types of heat-resisting alloys for use in burning racks were discussed by E. P. Poste. Studies on warpage and oxidation of the various alloys as compared with the cast iron and steel now commonly used seem to indicate that some of the alloys may be preferable. However, definite conclusions could not be drawn at this time.

Enamel Division elections gave the following results: B. T. Sweely, chairman; R. R. Danielson was re-elected secretary; councilors, H. F. Staley, R. D. Landrum, W. C. Lindemann, D. F. Riess.

Terra Cotta Division

Fire Cracking

Fire cracking occurs in terra cotta under certain conditions and is characterized by the appearance of sharp, hairline cracks extending into the bodies.

Experiments were made by E. C. Hill on firing large typical pieces made from various clays and grogs and cooling at different rates. The tendency to fire cracking was observed after weathering. The rate of cooling was found to have a much greater effect on the tendency to fire crack than the composition or physical properties of the body. Sandy clays gave more trouble than non-sandy vitrifying clays. The kind of grog is much less important in this respect than the kind of clay.

Shivering of Terra Cotta Glazes

Six terra cotta clays were tested for shivering as a body trouble by John L. Carruthers, using a white mat glaze, at cone 3 starting. One non-shivering clay and one badly shivering clay were experimented with to produce and overcome shivering.

Causes of Shivering. From this work and that of others which has been checked, the causes are:

(1) Presence of finely divided silica in the body from
  (*a*) highly siliceous clays,
  (*b*) finely ground grog of a siliceous nature.
(2) Presence of soluble salts in clay, grog or tempering water.
(3) Longer firing periods.

Elimination of Shivering. The methods suggested were:

(1) Use of a flux such as feldspar to overcome action of fine silica.
(2) Use of coarse grog or sand.
(3) Use of $BaCO_3$ to overcome effects of salts.

Other Division Meetings

Interesting meetings were also held by the Art, Heavy Clay Products and White Wares Divisions, in which matters of importance to the members were discussed, but lack of space precludes a detailed account here.

Contributions to the Study of Ammonia Catalysts—I

The First of an Important Series of Articles From the Fixed Nitrogen Research Laboratory, With Introductory Note by Richard C. Tolman, Director—Description of Apparatus for the Small-Scale Testing of Ammonia Catalysts at Atmospheric Pressure

By A. T. LARSON, W. L. NEWTON and W. HAWKINS

Introductory Note

ONE of the most important lines of investigation of the Fixed Nitrogen Research Laboratory[1] has been a study of the synthesis of ammonia from nitrogen and hydrogen. The marked success achieved during the last few years in Germany in applying this reaction to large-scale nitrogen fixation, together with the important attempts which have been made in this country and in France, Italy and England to utilize the same reaction, has emphasized the need of a broadly conceived study of the entire subject.

The problem of economical large-scale ammonia synthesis is one of the most complex known to chemical industry. It is capable of attack from a great variety of angles, and successful solution is perhaps possible under a wide variety of conditions. Thus the method developed in Germany, largely as a war emergency, is certainly not ideal and may not represent in any way the most satisfactory ultimate solution. The Fixed Nitrogen Research Laboratory has therefore studied, and is studying, the problem of ammonia synthesis from a broad viewpoint.

Among the most important phases of the problem is the development of suitable catalysts for accelerating the combination of nitrogen and hydrogen, and the testing of these catalysts under a wide range of conditions. The laboratory has prepared hundreds of catalysts, has developed testing plants for their study and has investigated their behavior over a wide range of pressure, temperature and other conditions.

After 2 years of intensive work the point has been reached where it is felt that an important service can be rendered to the scientific and industrial world by the publication of a series of papers containing a considerable part of the results obtained. It is by no means felt that the problem has been solved, but it is believed that the results so far obtained may enable the industries interested in nitrogen fixation to hasten their development, and may contribute materially toward the understanding of the complex phenomena of contact catalysis. The facts and theories in the published papers should be understood as representing the present status of the catalyst problem, in so far as the Fixed Nitrogen Research Laboratory is concerned, and not as any final word upon the subject.

In connection with these papers the laboratory wishes to acknowledge the aid of a number of men who have been or still are associated with the work and who have contributed materially to its progress, but whose names do not appear in the published papers. These include Dr. Arthur B. Lamb, former director of the laboratory; Dr. W. C. Bray, former associate director; Dr. R. O. E. Davis of the Bureau of Soils, and Dr. Graham Edgar, consulting chemist. RICHARD C. TOLMAN.

Copyright, 1922, by Fixed Nitrogen Research Laboratory.

[1]For a discussion of the history, organization and purposes of this laboratory, see Tolman, this journal (vol. 24, No. 14, April 6, 1921, p. 595). It should be noted that on July 1, 1921, the laboratory was transferred, with personnel and equipment, from the War Department to the Department of Agriculture.

Value of Tests at Atmospheric Pressure

A catalyst suitable for the commercial synthesis of ammonia from nitrogen and hydrogen will undoubtedly be required to operate at high pressures. Therefore, in an investigation of catalyst materials, the final tests must be made at high pressures; certainly unless it can be shown that the behavior of catalysts at high pressures can be rigorously predicted from the results of tests at lower pressures.

Testing at high pressures is, however, a slow, laborious and rather expensive procedure, not well suited for the rapid preliminary study of a large number and variety of catalysts. Testing at atmospheric pressure is relatively simple and rapid and the apparatus for it can be quickly installed from more or less standard laboratory equipment. This paper discusses the general procedure and describes the equipment which has been employed in the Fixed Nitrogen Research Laboratory for testing ammonia catalysts at atmospheric pressure.

Outline of Complete Apparatus and General Procedure

Before discussing individual items in detail it seems advisable to consider briefly the apparatus as a whole, referring to Figs. 1 and 2 for illustration.

Ammonia gas, expanded to atmospheric pressure from liquid ammonia, is passed through an electrically heated

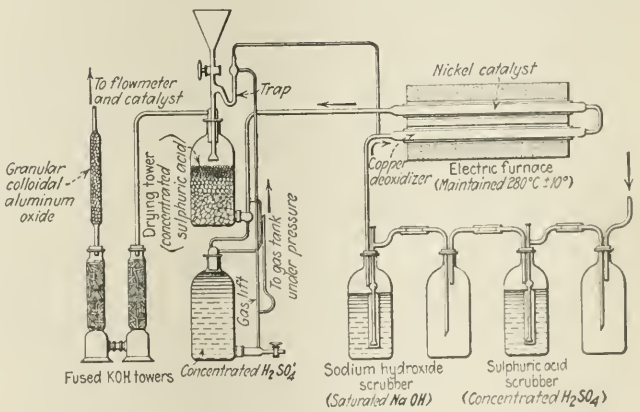

FIG. 1—ARRANGEMENT OF PURIFICATION SYSTEM

"cracker," in which it is decomposed into the 1:3 nitrogen: hydrogen mixture used for testing. This gas is then passed into a gasometer, from which it enters a purifying system (Fig. 1) consisting of a sulphuric acid scrubber to remove undecomposed ammonia; a sodium hydroxide scrubber to remove acid; a deoxidizer of heated copper; a heated nickel catalyst for hydrogenation of carbon monoxide and other substances; a drying tower of concentrated sulphuric acid; two towers of fused KOH;

and a tube of granular colloidal aluminum oxide. The purified gas then passes to a flowmeter and thence to the catalyst chamber proper (Fig. 2), a Pyrex glass tube heated in an ordinary combustion furnace and provided with devices for exact regulation and measurement of temperature. From the catalyst chamber the gas passes into absorption bulbs for analysis. When experiments are to be carried out upon moist gas, there is inserted in the line following the purification train a humidifier, from which the gas enters the catalyst chamber containing a definite amount of water vapor.

In general, the catalyst is introduced into the furnace in the form of metallic oxide and is reduced to metal *in situ* by heating in the same current of pure nitrogen: hydrogen used for testing. This procedure will be discussed more fully in the fourth article of this series.

Sources of Nitrogen: Hydrogen Mixtures for Testing

Commercial compressed nitrogen and hydrogen in cylinders, provided with reducing valves and flowmeters, may, of course, serve as the source of the 1:3 nitrogen: hydrogen mixture used for testing. However, such gases are apt to contain considerable amounts of impurities, and the precise regulation of the composition of the mixture presents an additional complication.

By decomposing ammonia gas by heat, a gas mixture is obtained of definite and invariable composition, containing nitrogen and hydrogen in the ratio desired for testing. Furthermore, by this method a large and readily adjustable supply of the gas mixture is supplied from a small and compact apparatus. This procedure has therefore been adopted for preparing the gases used in the experiments reported in this series of articles.

The Cracker

The construction of the ammonia cracker is shown in detail in Fig. 3. It consists essentially of three concentric cylinders 6, 5 and 3 in. in diameter, and 51, 50 and 63 in. long respectively, made from standard iron pipe and arranged as illustrated. Welded joints are used wherever screw connections are not shown.

The inner cylinder contains the heating element. This consists of 40 ft. of No. .04 nichrome wire first wound in a closed coil on a $\frac{3}{16}$-in. mandrel and then stretched to give the desired length and spacing between adjacent turns of the wire. The coil is drawn through a 36-in. porcelain tube having an outside diameter of $1\frac{1}{4}$ in. and is then wound spirally upon the outside of the tube as indicated. The porcelain tube is fitted with iron guides which serve to hold the nichrome coil in place and also to keep the heating unit centrally disposed within the 3-in. iron cylinder. Porcelain insulators are put around the wire where it passes under the metal guides. The assembled heating unit rests upon an alundum plate. The lead wires are passed through an insulating tube and are attached to the central electrodes of standard $\frac{1}{2}$-in. spark plugs. The lead wires are made sufficiently long so that each can be doubled back on itself. This tends to keep each lead relatively cool at the point where it is attached to the spark plug. A peephole of mica is provided at the top of the inner pipe, through which the heating coil may be observed for temperature regulation. The space between the 3-in. and 5-in. cylinders is packed with steel-wool and the whole apparatus is surrounded by a lagging of asbestos-magnesia. The ammonia gas enters at *A*, passes over the hot steel-wool, then up around the heating coil and finally out at *B* or at *C* as may be desired.

The cracker operates directly on 110-volt a.c. current and consumes $6\frac{1}{2}$ to 7 amperes. It will decompose about 200 liters of ammonia gas per hour, leaving less than 0.01 per cent of ammonia in the cracked gas.

Attention should be called to the following details: (1) Joints are made gas tight at flanges *D* and *E* by the use of asbestos graphite packing. (2) All pipe and fittings indicated are standard, the leads to and from the cracker being made from $\frac{3}{8}$-in. material. (3) The plate shown at the bottom of the 5-in. cylinder is welded on so as to make it gas tight. (4) The decomposer is essentially complete without the 6-in. outer shell. The ammonia gas, however, attacks the iron walls—that is, the 3-in. and 5-in. cylinders—and cracks are apt to develop which might cause considerable leakage of gas. The outer shell—that is, the 6-in. cylinder—serves pri-

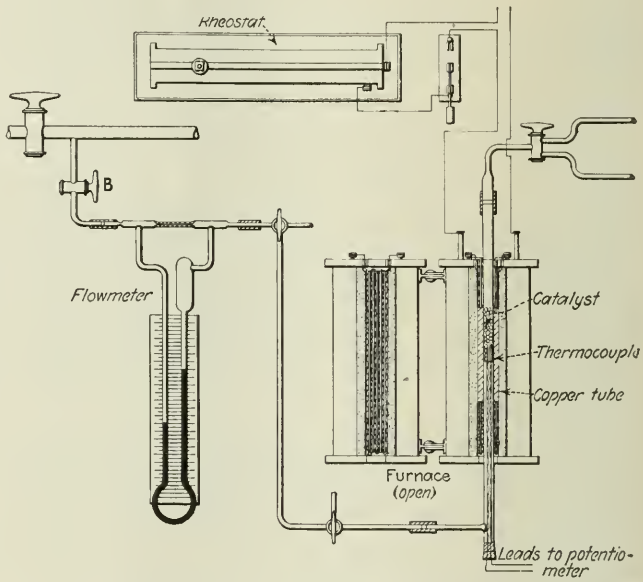

FIG. 2—FLOWMETER AND CATALYST TUBE AND FURNACE

marily to maintain the same pressure on both sides of the 5-in. cylinder. With this arrangement, even though the ammonia does attack the 5-in. cylinder, it does not become deformed, and leakage through this wall is avoided. It will be noted that the cracker may be operated in two different ways. First, the ammonia gas may be introduced at *A* and the decomposed gas drawn off at *B*. By keeping *C* closed the pressure on each side of the 5-in. cylinder remains the same, the pressure on the cracker as a whole being carried by the outside cylinder. Second, by closing the exit at *B* all the gas may be withdrawn at *C*. This has no advantage, however, over the first method suggested and in practice we prefer to withdraw the gas at *B*. At *C* we place a small cock from which we allow a very slow stream, say 5 to 10 c.c. per minute, of gas to escape.

In case the walls of the 3-in. and 5-in. cylinders do break down as a result of the action of the ammonia, this portion of the cracker may be easily removed by loosening the bolts in the flange *E* and withdrawing this portion of the apparatus. A replacement may then be introduced without disturbing the outer shell and the insulating material surrounding it.

Attention should also be called to the initial operation of a newly installed apparatus. The iron walls and piping are coated with oil, which is most conveniently

removed by heating the cracker slowly up to 500 to 600 deg. C. During this time a cylinder of cracked gas is attached at *B* and a slow stream of gas is allowed to escape at *A* and *C*. When the oil fumes have disappeared ammonia may be introduced at *A* and the cracker operated as indicated above.

For several days the efficiency of the cracker will be surprisingly low. After the steel-wool has become sufficiently activated so that the greater portion of the gas is decomposed in contact with its surface, the ammonia in the exit gases will be found to drop to about 0.01 per cent. The nichrome coil is heated to bright redness, the color of which can be observed through the mica window.

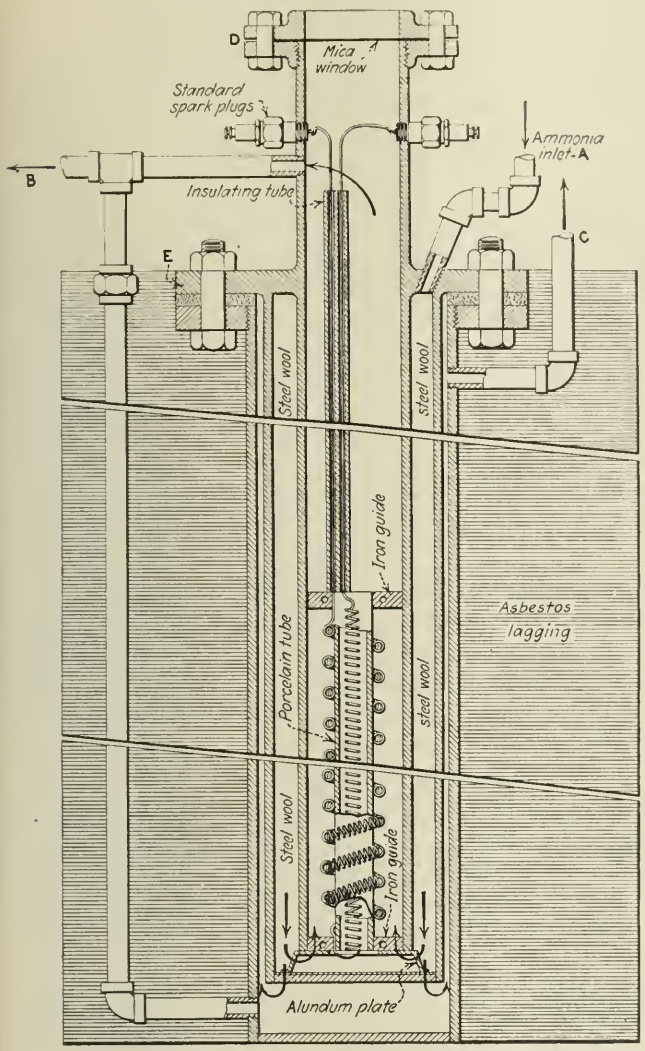

FIG. 3—SECTION THROUGH AMMONIA CRACKER

Purification of the Gas

The purification of the gas mixture is one of the most important factors, perhaps the most important factor, in determining the success of a catalyst-testing apparatus. Like most contact catalysts, the substances which are active in catalyzing the synthesis of ammonia are extremely susceptible to poisons. No intelligent conclusions as to the behavior of a catalyst can be drawn unless the gas used for testing is of the highest degree of purity or else contains definite and known quantities of particular impurities when desired. The poisons most frequently encountered are water vapor, carbon monoxide and acidic constituents. The purification train described below is designed to remove undecomposed ammonia which may have escaped the cracker and also any catalyst poisons which may be present in the cracked gas. What is equally important, it does not introduce impurities into the gas flowing through it, a source of error that is not always sufficiently guarded against.

Details of Purification System

Scrubbers

The individual items of the purifying system (Fig. 1) are described in detail below.

The concentrated sulphuric acid scrubber not only removes any undecomposed ammonia but also serves to absorb any unsaturated hydrocarbons which might be present in the liquid ammonia from which the nitrogen: hydrogen mixture is made. In order to avoid possible reduction of the sulphuric acid, with consequent introduction of sulphur dioxide into the gas, a little potassium dichromate is added to the acid.

The sodium hydroxide scrubber serves to remove acid spray picked up from the sulphuric acid and other acidic impurities possibly present. The solution is kept saturated with sodium hydroxide in order to keep the moisture content of the gas as low as possible.

The Deoxidizer

The gas passes from the alkali scrubber into a tube filled with metallic copper, and is heated to about 280 deg. C., which serves to remove the traces of oxygen which may be present. Whereas a fairly satisfactory copper catalyst for removal of oxygen from nitrogen: hydrogen mixtures may be made by low-temperature reduction of granules of commercial c.p. copper oxide, such a catalyst should be operated above 300 deg. C. for best results. Since in the present apparatus it is desired to heat the copper and nickel catalyst in the same furnace and since the nickel catalyst should not be heated above 300 deg. C. (see discussion following), a special copper catalyst is used. The catalyst is prepared as follows: A 6 to 8 per cent solution of copper nitrate is heated to 40 to 50 deg. C. and slowly added to a 5 to 6 per cent solution of warm sodium hydroxide in slight excess. The mixture is vigorously stirred while precipitation takes place. The precipitate is permitted to settle and the supernatant liquid is siphoned off. After thorough washing by decantation, the precipitate is washed dry on a Buchner funnel and the filter cake broken into 1-in. cubes and dried in a ventilated oven. During the first 12 hours the temperature of the oven is held at 80 to 90 deg. C. The temperature is then raised to 125 to 150 deg. C. and the drying continued for 24 hours. The hard compact granules are then broken up and screened to 4 to 8 mesh, which proves to be a convenient size.

The oxide is now placed in a catalyst tube, as shown in the figure, and is gradually heated to 300 deg. C. in a current of pure, dry nitrogen: hydrogen mixture. This reduced copper oxide is found to be highly pyrophoric, so considerable care must be exercised in keeping it from being exposed to the air. It has been found to work satisfactorily as a deoxidizer at 280 deg. C.

The Nickel Catalyst

From the deoxidizer the gas passes through a tube filled with a nickel catalyst, heated in the same furnace as the copper catalyst. Greenwood and Cowper (Munitions Invention Department. Ammonia Synthesis No.

12) have shown that small amounts of carbon monoxide are completely removed from hydrogen even at high space velocities by passing the gas over a properly prepared nickel catalyst at 250 to 300 deg. C. The carbon monoxide is converted into methane, which is inert toward ammonia catalysts. In addition to carbon monoxide, unsaturated hydrocarbons may be hydrogenated by the nickel. It may be noted that this catalyst would also remove oxygen from the gas (Greenwood and Neville, Munitions Invention Department, Ammonia Synthesis No. 65), but a rapid deterioration of the catalyst results from its exposure to high temperatures, and since this effect may be produced if appreciable quantities of oxygen are present, it was thought safer to precede the nickel by the copper catalyst described above.

The preparation of the nickel catalyst follows Greenwood's specifications. Nonpareil brick, crushed and screened to 4 to 8 mesh, is impregnated with sufficient nickel nitrate solution so that on subsequent ignition and reduction the product contains 10 per cent of metallic nickel. The material is dried at 150 deg. C., is placed in a catalyst tube, and is reduced at as low a temperature as possible in hydrogen or a nitrogen: hydrogen mixture. The catalyst is operated at 280 deg. C. ± 10 deg.

Final Scrubbers and Driers

From the nickel catalyst the gas passes to the sulphuric acid scrubbing tower containing broken glass and beads over which fresh concentrated sulphuric acid is circulated. The acid flow is maintained by a gas lift operated by an auxiliary supply of nitrogen: hydrogen mixture under pressure. The flow is adjusted by a reducing valve and a needle valve. It will be noted (Fig. 1) that the acid from the lift is caught in the trap, from which it trickles into the scrubbing tower. By this means introduction of any acid spray produced by the lift is avoided. The gas used to operate the lift is returned to the main line just ahead of the copper deoxidizer, thus avoiding wastage of gas.

If the acid in the scrubbing tower is kept reasonably fresh, a gas containing less than 0.001 per cent of water may be expected.

The acid scrubber is followed by two towers of fused KOH, which is an excellent drier and also serves to absorb any volatile acidic constituent which might be absorbed by the gas from the concentrated sulphuric acid.

From the KOH towers the gas passes into a tube containing highly porous aluminum oxide, which takes up water very effectively and also serves as a general absorbent, being particularly effective in removing any readily condensable gases.

The preparation of aluminum oxide is similar to that described above for the copper oxide, except that somewhat more dilute solutions are employed, that ammonia is used as precipitating agent, and that the precipitate is washed more thoroughly. The final drying is at 285 to 300 deg. C. The dried granules (6 to 8 mesh) are highly absorptive, and must therefore be kept out of contact with moist air.

Connecting Tubing

The gas issuing from the purification system passes into a copper manifold of $\frac{3}{16}$-in. copper tubing, from which in turn connection is made to twelve catalyst furnaces. A glass manifold, originally employed, was abandoned because of loss of time when breakage occurred. A manifold of standard iron piping was found to contaminate the gas, while a copper manifold has proved thoroughly satisfactory.

It should be noted that rubber tubing is to be avoided whenever possible. For example, 80 cm. of cold-cured tubing lowered the activity of a particular catalyst 95 per cent, and vulcanized tubing produced a similar effect. Considerable improvement is effected by treating the tubing with warm 10 per cent NaOH for several hours and then drying it; but in no case is it safe to use anything more than very short lengths of tubing, such as might be required to join glass tubes together.

Introduction of Moisture and Other Poisons When Desired

Moisture is introduced into the gas, when desired, by a humidifier, consisting essentially of a long horizontal glass tube half filled with water and maintained at a higher temperature than that at which it is desired to saturate the gas. The gas flows over the water in this tube and then passes through a copper coil immersed in water, kept at a temperature corresponding to the vapor pressure of water which it is desired to introduce. By this device saturation of the gas is effected from the supersaturation side rather than the undersaturation side, which gives more uniform results. In practice the glass bulb is usually maintained at room temperature and the copper coil in an ice bath, giving a gas containing 4 mm. of water vapor.

Carbon monoxide, the other poison whose effects have been studied, is introduced into the system by preparing a nitrogen: hydrogen mixture containing 1 per cent CO in a gasometer, introducing this into the line in such quantities as are desired, the operation of the nickel being omitted.

The Catalyst Tube and Furnace

The catalyst, usually 5 c.c. in volume, is contained in a 12- to 14-mm. Pyrex glass tube, about 30 cm. long. It is held in place by a perforated porcelain plate supported on a thermocouple insulator as shown in Fig. 2. A thermocouple junction is placed near the center of the catalyst mass.

A copper tube 6 in. long x $1\frac{1}{4}$ in. external and $\frac{5}{8}$ in. internal diameter slips over the catalyst tube and is supported by stout wires from the top of the furnace. The function of this tube is discussed below. The copper and glass tubes fit into a multiple unit (type 70) furnace with hinged top, connected in series with a rheostat. The furnace is employed in a vertical position, as shown in Fig. 2.

Control the Measurement of Gas Flow

The purified gas from the manifold passes through the cock *B* (Fig. 2), which serves to control the gas flow, and then passes through an ordinary glass flowmeter, from which direct connection is made to the catalyst tube as shown in the figure. The flowmeters are carefully calibrated by water displacement, using a stopwatch, and are known to be accurate within 5 per cent.[2]

Control and Measurement of Temperature

Temperature control in the cracker and in the copper: nickel catalyst furnace, requiring only approximate regulation, is effected by appropriate rheostats and is

[2] A discussion of the details of construction and calibration of these flowmeters is given in *J. Ind. Eng. Chem.*, vol. 11, p. 623 (1919).

measured optically in the case of the cracker and by a thermocouple in the catalyst furnace.

Temperature control and measurement in the catalyst furnace, however, represent a very important problem. In order to be able to draw correct conclusions concerning the behavior of catalysts, it is essential that all parts of the catalyst mass be at the same temperature and that the recorded temperatures be identical with those actually existing.

Uniformity of temperature is not easily obtainable in commercial types of tube furnace. Thus in the furnace employed in this investigation, there was a temperature difference of 10 to 25 deg. C. between top and bottom of the 4 c.c. of catalyst mass. These temperature differences did not vary appreciably with the rate of flow of the gas, showing that they were characteristic of the furnace itself. In order to eliminate these differences it is absolutely essential to smooth out the temperature gradient of the furnace, at least for the distance occupied by the catalyst. The external copper tube, previously described, effects this result most satisfactorily, the high thermal conductivity of the copper serving to distribute the heat in such a way that practical uniformity of temperature is secured throughout the entire catalyst.

A rheostat having fine gradations and connected in series serves to effect a very close adjustment of temperature.

Temperature is measured by means of a chromel-alumel thermocouple with its junction imbedded in the lower layers of the catalyst. The thermocouple wires are insulated by means of a two-holed fireclay protection tube which is supported at its lower end by a rubber stopper. The wires are sealed gas tight in the end of the fireclay tube by means of de Khotinsky cement. Below the rubber stopper the thermocouple wires are attached to copper wires leading to a Leeds & Northrup potentiometer, sufficiently sensitive to permit the estimation of temperature to 1 deg. C. The thermocouples are frequently calibrated by heating them in a vapor bath of boiling sulphur.

Analytical Control

Since the effectiveness of the catalyst is determined by the ratio of ammonia to nitrogen: hydrogen in the outflowing gas, this represents the only necessary analytical determination. At atmospheric pressure the amount of ammonia must always be very small, necessitating the use of a large sample of gas for analysis. In practice, therefore, a Gomberg gas-washing bottle containing standard sulphuric acid is attached to the outlet gas, and the gas current is maintained for a definite time, the flowmeter and stopwatch readings permitting the calculation of total gas volume. The ammonia is then determined by titrating the excess of acid with standard alkali, using methyl red as indicator.

Results

The apparatus described above has been employed in the Fixed Nitrogen Research Laboratory for the testing of a large number of ammonia catalysts and for studying the influence of temperature, rate of flow of gases, catalyst poisons and other factors entering into catalyst behavior. Results of these investigations will appear in the fourth article of this series.

(Part II, which discusses Small-Scale Testing of Ammonia Catalysts at Variable Pressures, will be published in a subsequent issue.)

Cancer From Handling Anthracene Cake in the Dye Industry

The use of anthracene, which is the starting point of the alizarine dye industry, has been shown by W. J. O'Donovan,[1] writing in the *British Journal of Dermatology and Syphilis*, to be capable of producing cancer of the skin among workers handling the crude anthracene cake. Anthracene in the cases reported was delivered to the factory in the form of cake which was unloaded by hand and broken down, exposed to steam, and washed with solvent naphtha mixed with pyridene bases; the product was then distilled with potash and lime, washed with solvent naphtha, and finally sublimed.

The three cases reported were brought to the writer's attention within a period of about 4 months, and in a factory employing only about twenty-five men this was considered by him as "a heavy incidence of a grave industrial disease."

The first case was that of a man 62 years old who had been employed for 5 years in unloading boxes and sacks containing the raw cake. On the back of the right wrist was an ulcer with raised edges which proved to be a scaly and horny-celled carcinoma. The growth which was removed had started as a small wart 6 months previously. His forearms also showed much dilatation of the capillaries and small blood vessels and follicular keratoses, a form of acne. The second case occurred in a man aged 53 who had worked for 30 years in the same factory. A cancer of the same nature had appeared on his right cheek 3 months before and had grown very rapidly. Under treatment by radium it entirely disappeared. The third case was that of a man 59 years of age who had worked in the factory 32 years and who had developed an ulcer on the right wrist 4 years previously. This ulcer had developed rapidly in the preceding 6 months and upon excision was found to be a cancer of the same nature as in the other two cases.

All the men working in this factory who in any way handled the crude anthracene showed a deep staining of the hands and faces. Their hands were stained a deep brown, sometimes almost green, their faces and necks were very swarthy and there were also acne papules on their necks and forearms.

Business in Chile Awaits Lower Nitrate Price

Conditions in Chile, reported to be improving during December, 1921, remained stationary during January and February and are still awaiting a betterment in the nitrate trade of Europe and the United States, says Commercial Attaché McQueen in a cable to the Department of Commerce.

The prices on nitrate which were fixed on Oct. 27, 1921, terminate on June 30, 1922, and lower prices are expected thereafter. The nitrate producers hope to see the reduced prices hasten the marketing of the present stocks in Europe and the United States and a consequent general improvement after the middle of the year. Imports and exports are decreasing, the foreign and domestic demand continuing dull. There has been no appreciable addition to import stocks since October, 1921.

The agreement made between the miners and operators of the coal districts of southern Chile terminated Dec. 31, 1921, following which a walkout and strike was called. This, however, has recently ended in failure for the miners.

The Froth Flotation of Coal

A Discussion of Research Work on the Recovery of Washery Refuse and Unconsumed Coal in Ashes—The Commercial Utilization of the Froth Concentrate

By OLIVER C. RALSTON[1] and ARTHUR P. WICHMANN[2]

With the exhaustion of the seams of coal which are low in ash content and with the increased cost of coal, problems in the removal of ash have assumed increasing importance. The use of jigs for removing the slate and other impurities from coarse coal has long been standard practice. More recently, ore-concentrating tables have been adapted to the "washing" of the finer sizes of coal in the coal washeries and have saved material that was formerly wasted, because there is a poor market for fine sizes of coal. However, the slime formed in breaking the coal before washing has been entirely discarded, for the reason that it has not been salable even when recovered. Just as was the case in ore-dressing not many years ago, the indications are now that the slime formed in the mill will become sufficiently valuable to save. Also, when the advantages to be gained by the use of clean coal are fully appreciated, it is possible that fine grinding and flotation or other treatment of low-grade coals, formerly considered worthless, will result as it did in the case of finely disseminated ores. While it is not at all certain that such methods will find a commercial field, it was thought well worth while to investigate the applicability of froth flotation to cleaning finely ground coal in order to see just what technical problems would arise and what advantages could be gained.

Since an investigation of the coals of the Pacific Northwest with respect to the possibilities of their improvement by ordinary methods of coal washing was already under way at the Northwest Experiment Station of the Bureau of Mines, in co-operation with the College of Mines of the University of Washington at Seattle, this study of the applicability of froth flotation to the fine sizes of coal was carried out to supplement the coal-washing program.

Products to Which Froth Flotation Might Be Applied

The most obvious product to which froth flotation might be applied is the coal slime produced by crushing coal in washeries and to the finer sizes of coal which cannot be washed very cleanly on coal-washing tables. Huge piles of coal sludges and culm have also accumulated from past washing operations and are available.

Coarse washery refuse often contains considerable interstratified coal which could be liberated by crushing, permitting the coarser material to be recovered by tables and the fine material by flotation.

Mine waste also frequently contains considerable material like the coarse washery waste which might be advantageously crushed and treated for its coal content.

Run-of-mine coal, when too high in ash that is not liberated by crushing to form the ordinary sizes of lump, egg, nut, pea and buckwheat, might even be more finely ground and treated by flotation.

The ash from domestic and industrial furnaces contains considerable unconsumed coal, the average ash of the United States probably containing 20 per cent of combustible matter. Coal-flotation plants might be located near large cities to crush and recover coal from the ash produced in these cities.

Of these possible products which might be treated, two have already received relatively large-scale tests—washery fines and unconsumed coal in ashes.

Review of Previous Work

The idea of using flotation for recovery of coal from fine washery waste is not new. Small laboratory tests on material of this kind were observed by one of the present writers as far back as 1915 in various flotation-testing laboratories of the United States. In one instance the film flotation machines of the Empire Zinc Co., in Canyon City, Col., had been tested for recovery of anthracite from the anthracite culm material known to be so plentiful in Pennsylvania, cleaner concentrate being obtained than by froth flotation. The idea had been passed around in a confidential way among flotation engineers. The first U. S. patent was issued to Raymond F. Bacon, of the Mellon Institute, Pittsburgh, Pa. (U. S. Patent 1,329,493, of Feb. 3, 1920), who assigned it to the Metals Recovery Co. of New York. Bacon described tests with a Callow pneumatic flotation test machine on coal washery waste and on run-of-mine coal crushed to pass a 48-mesh screen and mentioned the fact that lustrous coal in sharp angular fragments was the most easily floated.

Minerals Separation, Ltd., in England, also began patenting features of coal flotation[3] in 1919 and later[4] in that year built at the plant of the Skinningrove Iron Co., in Wales, a test plant to investigate the removal of ash from the coking coal used by that company, a problem which was giving considerable concern. The reports on this work appeared after the present writers had done all of their own work and not only checked their observations but supplemented them to some extent.

In view of this prior publication we shall not attempt to report our own results in detail but shall give them

only in abstract, reviewing at the same time the work which has been done in Wales.

The material in a coal seam may contain all gradations from pure coal with almost no ash to pure ash. It has been more or less arbitrarily divided into the following types of material: Pure coal, containing up to 5 per cent ash; bony coal, containing from 5 to 15 per cent ash; bone, containing 15 to 50 per cent ash; bituminous shale, containing 50 to 80 per cent ash and pure shale rock or ash with very little bituminous matter.

The Suitability of Various Flotation Oils

In all the various coals tested it has been found that the pure coal is the most easily floated,[5] and the other products follow in order. Since the division between them is merely arbitrary, their behavior in the flotation machine is quite similar and it is almost impossible to distinguish visually one from the other in the froth. The most favorable oil discovered in the work in England was the waste water from the absorption and washing of crude naphthalene in an adjacent byproduct coking plant, whereas our most favorable oil was a mixture of alphanaphthalamine (known to the flotation trade as X-cake) with xylidine in sufficient quantity to keep it in solution. Both of these are practically entirely water solutions of coal-tar products and seem to be adapted best to making the pure coal float first. They are commonly regarded as "frothers" and not very good collectors. When petroleum products or other wood or coal-distillation products such as creosotes, tars or essential wood oils are added, the flotation of the other portions of the coal results.

The British experimenters have said: "If we were asked to state the most striking fact in the application of the process to coal washing, we would refer without hesitation to the facility with which it separates one grade of coal from another merely by the simple control of reagents and without the aid of any form of screening or classification." This observation we are unable to check. Our work has been almost entirely restricted to the bony coals and bone coals of the Pacific Northwest and we have observed a marked tendency of the coal to separate in this manner, but we certainly cannot feel that this is done with any "facility." Had we been working with some of the fine low-ash coals of Wales we might have been able to agree.

If a high extraction of combustible matter is the desideratum rather than low ash concentrate, any of the ordinary flotation oils easily recovers all the pure coal, bony coal and bone together. There is no difficulty whatever in getting coal to enter a flotation froth and in fact we have found our greatest embarrassment in the tendency of all the bituminous matter to float with the clean coal. Pine oil and similar frothers cause trouble of this kind. Quite evidently the best condition for the procurement of a clean coal froth is a relatively poor flotation condition, just as in the differential flotation separation of mixtures of sulphide minerals conditions must be found under which one mineral can barely be floated while the other or others will not float at all.

Skinningrove Iron Co. Tests

This test plant, as well as one built at the Powell-Duffyn Colliery, Aberdare, England, treated the high ash products obtained in the washery where a coking coal was prepared for the ovens. The material liberated a high percentage of low-ash coal by simple crushing to pass a 10-mesh sieve, and this material was treated in Minerals Separation flotation machines, using as a flotation reagent the wash water from the naphthalene recovery section of the byproducts coking plant. The ingoing material contained from 13 to 45 per cent ash and the froth concentrate of cleaned coal contained as low as 3.5 per cent ash—a truly remarkable result when compared to what can be done with the ordinary types of coals available in the United States. A screen analysis of the froth concentrate shows that the material passing a 10-mesh and stopping on a 20-mesh screen contains only 2.7 per cent ash, while the material passing a 200-mesh screen contains 5.9 per cent ash, the tendency being for progressively smaller sizes of the coal in the concentrate to be progressively dirtier. Our own results on higher-ash coals check this.

The froth was thickened in a Dorr tank to 50 per cent solids and then passed over an Oliver continuous filter, yielding a product said to contain about 10 per cent moisture. It was felt that this was too much moisture to be fed economically into the coke ovens and preparations were being made to reduce it further in a drier. Nevertheless this material was easily coked in ordinary byproduct ovens and the low-ash coke afforded a considerable economy, estimated at slightly over 3 shillings per ton of pig iron produced with the coke. The advantages of treating the coking coal by this method in order to make coke for the iron industry are summarized by Bury, Broadbridge and Hutchinson as follows:

Advantages of the Method

(1) Ash reduction. Saving in cost of handling, particularly where the place of the production of material to be coked is some distance from the coke ovens.

(2) Economy in coking. The product is more highly bituminous, yields richer gas, more byproducts and about the same yield of coke.

(3) Superior coke. The coke produced is low in ash and also highly porous but very strong and dense.

(4) Economy in furnace space. More room for iron ore and fuels.

(5) Minimum silica, since ash reduction calls for less lime and hence less coke.

(6) Dense coke means less fines. This avoids loss of coke fines and must be screened out.

(7) Thermal efficiency. Less slag produced to carry out heat.

(8) Maximum thermal efficiency at smelting zone, because coke does not shatter and burn up before it reaches this zone.

A typical test on this Welsh coal containing 10.14 per cent ash gave 87.2 per cent by weight of pure coal concentrate with 3.25 per cent ash, 2.4 per cent second concentrate (bone) with 19.2 per cent ash and 9.5 per cent of residue with 72.1 per cent ash.

This work in England proved to be very valuable and profitable to those entering into it for the reason that it was possible to recover cheaply from the old waste dumps that had accumulated for years a great deal of coal at a time when the nation was suffering from coal shortage caused by strikes and high cost of production.

Recovery of Coal From Ashes

The unconsumed coal in domestic and industrial ashes, mentioned as one of the products to which flotation should be applicable, has been experimented on by

[5]One exception to this has been reported in a private communication from the superintendent of the Rare and Precious Metals Experiment Station at Reno. A bony lignite from western Nevada gave a first concentrate higher in ash than the later products taken from the flotation machine.

Fraser and Yancy[6] at the Urbana experiment station of the Bureau of Mines, where rather large tests were made on the use of coal-washing tables for this work. The ashes were crushed to about $\frac{3}{8}$ to $\frac{1}{4}$ in. before tabling. The washed fuel recovered contained about 25 per cent ash. Such material has been tested qualitatively by the writers, using froth flotation, and the combustible material forms a black froth in sharp distinction to the light-colored ash suspended in the water. However, no quantitative tests have been made. H. B. Hoveland, in his laboratory in Washington, D. C., was one of the first to use froth flotation on such ash, but his results were not available.

Froth Flotation of Pacific Northwest Coals

Representative results of some of our tests on the coals of the Pacific Northwest are briefly abstracted in Table I. They were obtained when we were learning how to float coal and are not nearly as good as might be obtained with better and more closely controlled conditions. Many of them show high-ash froths due to excessive use of the oils which float the bone with the cleaner coal. Very few of them were carried out with the idea of making a high recovery of combustible matter, but rather an attempt was made to produce clean concentrate. Frequently a test was stopped after only a small portion of the coal had been floated.

TABLE I.

Product Treated	Source	Per Cent Ash In Feed	Per Cent Ash In Concentrate	Per Cent Recovery Combustible	Oil Used — Kind	Oil Used — Lb. Per Ton
Sub-bituminous table middling	Mendota, Wash.	47.85	25.66	71.2	Pine oil (steam-distilled)	1.5
Sub-bituminous run-of-mine	Renton, Wash.	28.75	23.75	44.9	Coal tar-pine oil	2.0
Sub-bituminous washery sludge	Renton, Wash.	19.38	10.66	34.6	Coal tar-hardwood oil	3.0
Sub-bituminous fine screenings	Bellingham, Wash.	22.65	13.30	54.1	Hardwood creosote	2.0
Sub-bituminous run-of-mine	Isaquah, Wash.	33.25	22.38	33.6	Kerosene-pine oil	8.0
Sub-bituminous washery sludge	Isaquah, Wash.	29.35	17.10	11.8	Kerosene-pine oil	2.0
Coking bituminous, table middling	Palmer, Wash.	30.01	20.00	76.7	Pine oil	0.5
Coking bituminous, run-of-mine	Carbon Co., Utah	6.00	4.00	61.4	Pine oil	0.7
Coking bituminous, run-of-mine	Ladysmith, B. C.	8.60	4.95	73.7	Pine oil	0.25
Non-coking bituminous, run-of-mine	Roslyn, Wash.	17.80	9.98	56.1	Pine oil	0.6
Non-coking bituminous, run-of-mine	Roslyn, Wash.	24.15	13.43	72.6	Kerosene oil	1.0
Non-coking bituminous, run-of-mine	Carbonado, Wash.	18.65	10.37	60.0	Pine oil	0.8
Coking bituminous, run-of-mine	Carbonado, Wash.	9.50	7.33	52.0	Pine oil	0.8
Semi-anthracite, run-of-mine	Carbonado, Wash.	8.02	4.38	64.2	Pine oil	0.8
Coking bituminous, run-of-mine	Wilkeson, Wash.	14.38	10.73	60.0	Pine oil	0.5
Coke (beehive)	Wilkeson, Wash.	18.50	16.10	66.8	Pine oil	0.4
Coke (beehive)	Fairfax, Wash.	23.65	18.00	60.8	Pine oil	1.0

The work represented in Table I was done in an ordinary Minerals Separation type flotation machine. The opinion was formed that this machine was not well adapted to the froth flotation of coal, as it seemed to require the addition of too much oil to the pulp. Later work in a Ruth machine, which corresponds to a sub-aërated Minerals Separation machine, proved this to be true, as much less oil could be used in the Ruth machine in order to get a satisfactory loaded froth.

TABLE II.

Sample	Per Cent Ash Feed	Per Cent Ash Concentrate
Total	22.65	17.14
Pass 60 mesh, held on 200 mesh	21.57	15.63
Pass 200 mesh	25.20	19.32

The coal seems to absorb the excess of oil from the water so that the frothing properties of the water are soon spoiled. Incidentally the fine coal seems to become overoiled and to form a dirty froth. This is illustrated by a screen analysis made on the feed and the concentrate of one of the tests with Bellingham sub-bituminous coal, which are given in Table II.

[6] Thomas Fraser and H. F. Yancey, *Reports of Investigations*, Bureau of Mines, Serial 2281, September, 1921.

TABLE III.

Coal Treated	Source	Feed Per Cent Ash	First Concentration Weight Per Cent	First Concentration Ash Per Cent	Second Concentration Weight Per Cent	Second Concentration Ash Per Cent	Tailing Weight Per Cent	Tailing Ash Per Cent
Sub-bituminous	Renton, Wash.	19.4	32.0	10.7	35.0	14.0	33.0	33.2
Sub-bituminous	Bellingham, Wash.	22.7	70.0	13.5	15.0	26.9	15.0	57.0
Bituminous	Roslyn, Wash.	17.8	33.0	10.1	49.0	11.4	19.0	51.0
Bituminous	Roslyn, Wash.	17.9	77.0	12.4	19.0	30.1	4.0	73.3
Coking bituminous	Carbonado, Wash.	8.0	61.6	4.4	34.1	9.8	3.4	62.5

Incidentally, the oil mixture used in this test was found to be rather non-selective and too much of a collector. It consisted of 50 per cent hardwood creosote and 50 per cent coal tar creosote used in the proportion of 2 lb. per ton of coal.

A few representative figures showing the way in which a coal tended to divide into several products, the cleanest being floated first, are given in Table III, which deals with two sub-bituminous coals, two non-coking bituminous coals and one coking coal. The first four were quite bony and the last was fairly clean without so much bone.

There seems to be no doubt that many coals can be considerably improved by froth flotation, though the bony coals are quite refractory toward the process. Assuming that there is a demand for it, some clean coal can undoubtedly be extracted from nearly all coals by utilizing the above-mentioned selective tendency to float clean coal first. This being true, the next real problem is the commercial disposal of the finely divided froth concentrate. It must first be dewatered, and this is no easy problem. With the relatively coarse material produced by the Minerals Separation work in England, a satisfactory result seems to have been obtained by using a Dorr thickener followed by an Oliver filter to bring the moisture content down to 10 per cent. However, there are few coals in the United States as clean as the coals experimented with in England and finer grinding than 10 mesh will doubtless be necessary in order to liberate more of the ash. This will give a product which will not settle so readily nor filter so easily. After a filter cake of the consistency of thick mud is discharged from the revolving filter, there is a serious question as to what to do with it.

Disposal of the Concentrate

Various proposals for the disposal of this concentrate are to be considered. One is to dry it out sufficiently to be used for powdered coal combustion appliances. Probably it would have to be ground somewhat further, or at least the lumps would have to be disintegrated,

so a regular coal-pulverizing machine would still be necessary, although it would have a very high capacity.

Another proposal would be to briquet the material and burn it in that form. W. Broadbridge, one of the Minerals Separation engineers, has secured a British patent[7] for this proposal in which he states that it can be briquetted by the use of 7 per cent of pitch or 5 per cent of pitch mixed with some cresol and kerosene. These percentages are calculated on the dry weight of the coal. The binder may be introduced into the froth concentrate in the liquid state or may even be used to produce the flotation and simultaneously provide the binding medium. Our results show that if enough oil to bind the material into briquets is introduced into the flotation pulp it will probably cause the non-selective flotation of all bituminous matter, leaving only the pure ash in the residue. This method could therefore be used to advantage only on coals containing no bony matter.

Still another proposal is to prepare the froth concentrate for the coke oven by dewatering as was done at the Skinningrove Iron Co. plant, except that with finely ground material or even with the 10-mesh material handled in that plant there is still too much moisture in the filter cake. It is probable that a partial drying of the filter cake in a rotary drier would be sufficient. At a certain critical percentage of moisture any mud or finely divided damp material will roll up into little balls when tumbled about in a machine like the rotary kiln drier. These little balls should make good material for feeding to a coke oven, as they would leave enough space between them to provide gas passages for escape of the coke-oven gas and avoid the "vomiting" which sometimes occurs with a closely packed, finely divided charge.

Summary and Conclusions

The work of the writers on a series of coals of the Pacific Northwest, most of them bony, taken in conjunction with the reports of the work of Minerals Separation, Ltd., in England, seems to justify the following conclusions about the applicability of froth flotation to the cleaning of coals:

(1) Due to unexplained difficulties, very finely ground coal slime does not concentrate well by flotation and the process is limited to the treatment of the more granular material. Whereas the finer sizes should give a cleaner concentrate, they actually give a dirtier one.

(2) Coals with a bright luster have been found to concentrate more cleanly than dull coals.

(3) There are indications that cleaner flotation is obtained when the coal is broken into sharp angular fragments than when ground down to rounded pieces.

(4) While in general the coals of higher rank, like the semi-anthracite and the coking coals, are more amenable to flotation, this is not essentially so, as some of the sub-bituminous coals have been successfully floated.

(5) The mode of occurrence of the ash in the coal is most highly important, as it has been found that most of the ash present in bony coal and bone coal cannot be liberated by the finest attainable commercial grinding.

(6) The free clean ash can be left in the flotation tailing and the remainder of the coal can easily be floated away from it.

(7) The cleanest coal is the most easily floated, providing the flotation oil consists of a poor frother with no collector and a sub-aëration or pneumatic flotation machine is used.

(8) Bone coal floats almost as easily as clean coal, but will require the use of a better frothing oil and some collector for complete extraction.

(9) Bituminous shale is somewhat less easily floated than bone coal.

(10) For grading a coal by flotation into clean coal, bone, bituminous shale and free ash, careful control and the use of differential flotation methods is necessary.

(11) Flotation tests on removing the ash from finely ground coke have not shown much success.

Investigations of Iron Blast-Furnace Operation

The blast-furnace research section of the Bureau of Mines, located at Minneapolis, Minn., has carried out plant investigations for 6 years; these are being continued. The conviction has been forced on it, however, that little progress toward the solution of the many important problems involved in furnace operation will, or can, be solved by any method of study of commercial operations on account of the large amount of materials to be handled in these operations and the numerous causes of irregularities. The need of a furnace capable of operating on a small scale and under controllable conditions has been obvious for years. In the last year an experimental stack has been erected and twelve combinations of furnace lines and operating conditions have been tried out. This work is being continued.

The blast furnace works on the countercurrent principle; the ascending gas stream encountering the descending raw materials, with a regenerative transfer of heat. Maximum contact between gas stream and raw materials produces most rapid heat transfer and reduction of the ore. The degree of contact between gas stream and solid charge depends to a very large extent upon the size and shape of the furnace, and the investigation is planned with a view of acquiring data which will enable the engineer to design the furnace more rationally.

Another investigation relates to the effect of physical characteristics of the charge on blast-furnace operation. Probably the greatest cause of the fundamental inefficiency of the blast furnace considered thermally as a furnace is due to the enormous disparity between the sizes of the particles of the solids charged. In a number of cases furnace operators have improved furnace efficiency by sizing the coke charge. There are prospects of being able to continue such work on the sizing, not only of the coke but of the ore.

A laboratory study of the time rate of reduction of iron oxides by carbon monoxide is under way. The reducing gas employed will be 35 per cent CO and 65 per cent N_2. The iron oxide will be obtained from the higher grade Lake Superior shipping ores and the reducing gas will be driven through the ore bed at such rates of speed as obtained in blast-furnace operation—i e., about 25 ft. a second. The rate of the reaction is known to depend primarily upon the gas velocity and the size of the ore particles. To a lesser extent the reaction will depend upon the temperature and the composition of the reducing gas.

Former investigations have been confined to a study of the reactions between iron oxides and carbon oxides, undiluted by nitrogen. The new work will therefore more nearly approximate furnace conditions.

Notes on the Manufacture of High-Speed and Tungsten Steels

Massive Carbides Were Separated From High-Speed Steel, Analyzed, and Found to Approximate the Composition of the Ferrotungsten Used in Their Manufacture—Structural Disposition of These Carbides After Various Heat-Treatments, With or Without Previous Mechanical Work

By J. W. WEITZENKORN
Vice-President and General Manager, Molybdenum Corporation of America

IN THE following the writer traces the steps taken in studying segregation in high-speed and tungsten steel. Valuable information is thus developed which may enable the steelmaker to eliminate some of the troubles in manufacturing tungsten steels and to produce a better product.

Ferrotungsten Better Than Metal

In the making of high-speed and tungsten steels tungsten is introduced either as ferrotungsten or as so-called metallic tungsten powder. It seems more logical to use the ferro-alloy; through its use not only will the final product be superior, but also many of the difficulties which are met in the production of tungsten steels can be eliminated.

The temperature of the average crucible furnace is from 2,900 to 3,100 deg. F., that of the electric furnace somewhat higher. The melting point of pure tungsten is about 6,400 deg. F. On the other hand, a ferro containing about 75 per cent tungsten melts in the neighborhood of 3,700 deg. F.; as the iron content increases, the melting point decreases, and the carbon content has a similar though less marked effect.

Due to the very high melting point of even commercial tungsten metal, it is necessary to observe certain precautions in smelting in order to prevent the tungsten metal, which alloys but slowly with the iron, from segregating, particularly in crucible practice. This segregation is sometimes so extensive that a button forms in the shape of a pancake in the bottom of the crucible. This button has always been found to carry a high percentage of tungsten and possesses a melting point higher than that of the steel, with the result that it was not sufficiently fluid to pour from the pot with the rest of the contents. The composition of one such button was C 0.83, Si 0.73, Cr 11.57, W 57.10, and Fe 31.07. The desired composition of the steel being melted was C 0.5 to 0.6, Mn 0.2 to 0.3, Cr 4.0 to 5.0 and W 20.0. In this instance the tungsten metal, as it settled to the bottom of the crucible in the course of the melting process, absorbed some of the ferrochromium of the charge; hence the high percentage of chromium.

This segregation is usually prevented in crucible practice in one of three ways:

First, the tungsten is added shortly before teeming.

Second, tungsten is distributed through the upper part of the charge, so that as the iron melts, the tungsten, on account of its greater specific gravity, passes down through the melt, giving it a chance to be alloyed with the iron by the time it reaches the bottom of the crucible.

Third, an agitation or boiling is produced, either by placing oxides at the bottom of the crucible or introducing oxides during the course of the melt, which tends to hasten the absorption of the tungsten.

The first method is not readily carried out and is considered impracticable by the greater number of steelmakers. The second procedure does not entirely prevent segregation when the tungsten is introduced as metallic powder, on account of its high melting point and slow alloying property. The third method is more widely used, but it is generally accepted that oxides are injurious to fine steel and every effort is bent toward their removal. Their introduction, therefore, would seem to be a step in the wrong direction, for it is very likely that the oxides are not completely removed by the subsequent melting and deoxidizing. Furthermore chromium, one of the essential constituents of high-speed steel, is readily oxidized. When combined with the oxide of iron, it forms one of the most highly refractory and inert combinations, one exceedingly difficult to eliminate when once formed, and when retained produces steel which can be forged with difficulty, and is likely to be brittle and probably crack during hardening.

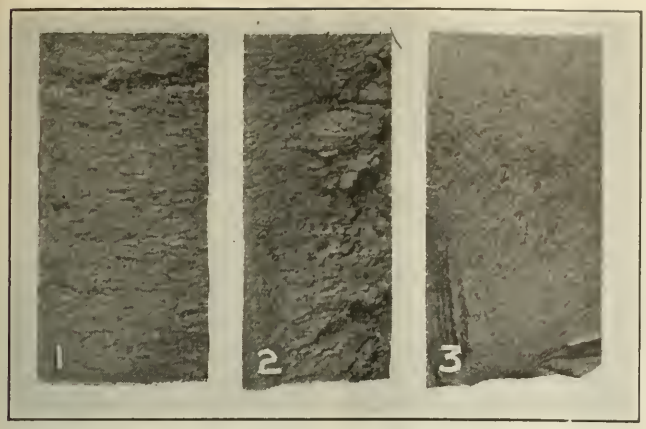
Ferrotungsten, on the other hand, readily alloys with the steel. As noted above, its melting point is much lower than metallic tungsten and likewise its specific gravity. Furthermore the tungsten, iron and carbon in ferrotungsten are already alloyed in somewhat similar chemical combinations and physical constituents to those existing in high-speed steel. The striking similarity which exists between the comoposite carbides found in high-speed steel and ferrotungsten will be apparent from what follows.

C. Mennicke, who compiled a most interesting and complete study of tungsten, in his book "Metallurgie des Wolframs" states that "the use of ferrotungsten in the manufacture of tungsten steels is beyond doubt superior, easier to handle and more effective than metallic tungsten." To this the writer would add that if the ferrotungsten is broken or crushed to the size of rice or of pea, it is in that condition readily handled in the mixing room and produces a cleaner, more homogeneous product, freer from segregation, oxides, slag and such foreign inclosures. In fact, the use of metallic tungsten is based on no logical conclusions, and experience shows a marked tendency toward the use of lower melting and easier combining tungsten alloys until now but few steelmakers have continued the older practice of using metallic tungsten.

Ingotism

Occasionally small sections but more frequently large ones exhibit a dull, fibrous or woody fracture, both in the annealed and hardened state (Figs. 1 and 2), instead of the characteristic fine, porcelanic fracture of normal high-speed steel shown in Fig. 3.

Microscopic examination of sections showing this fibrous condition indicates that it is caused by a eutecti-



FIGS. 1 TO 3—FRACTURES OF HIGH-SPEED STEEL. ABOUT TWICE SIZE.

Fig. 1—Defective steel, hardened. Dull and fibrous fracture.
Fig. 2—Defective steel, annealed. Dull and fibrous fracture.
Fig. 3—Good steel, annealed. Fine, porcelanic fracture.

form segregation of carbides, which forms during the solidification of the molten steel. For convenience this structure will be referred to as "ingotism," from its nature and origin.

When "ingotism" is noted to a very marked degree in high-speed steel it causes the steel to be difficult to anneal, to possess hard and soft spots after annealing, to possess a coarse fibrous fracture in the annealed and hardened condition, to tear and show bright streaks upon machining, to be somewhat "brittle" or short, even in the annealed condition, to develop cracks in hardening which tend to follow the segregated carbides, to lower cutting efficiency, and to interfere slightly with secondary hardening, that characteristic increase in hardness on drawing hardened tools to about 1,000 to 1,100 deg. F.

In the ingot condition segregated carbides assume a "pine" or "fern-leaf" formation, which can often be noted in large-size commercial bars and frequently traced in smaller sizes, depending upon the amount of work that the steel received. Mechanical work and heat break up the segregations, as is shown in the series of microphotographs,[1] Figs. 4 to 7 inclusive. A 15-in. octagon billet was forged (at a temperature of 1,900 to 2,000 deg. F.) into billet, bar and rod, microscopic studies being made at intervals. Fracture of a piece with structure like Fig. 4 was coarse and fibrous. Fig. 7 shows the retention of only a "ghost" of the original ingotism, and in the annealed a hardened condition should show a fine porcelanic fracture.

[1]All sections were etched with 10 per cent HNO_3 in alcohol.

In large ingots, where the segregation is more marked on account of its slower rate of cooling, it requires a reduction of about 90 per cent in section area to break up this structure. Furthermore it was frequently noted in bars made from large ingots (10, 12 or 15 in. octagon) that the outside of such bars are almost completely refined, due to that portion having received a comparatively large amount of hot work, whereas the centers, which received less work, show less refinement.

When starting with smaller size ingots, such as 4-in. octagon, the fern-leaf segregation is not as marked, due to more rapid cooling, and is therefore more easily broken up by forging and may be entirely eliminated upon reducing the section to 65 to 75 per cent. Sometimes it may be done with a very small amount of work, depending, however, on whether segregation was suppressed by the casting conditions; high casting temperature and slow cooling favoring "ingotism."

Mechanism of Solidification

As noted by the writer, the origin of these segregations of carbides in high-speed steel with very few exceptions can be traced to eutectiform masses and their position and formation attributed to "ingotism." It is difficult if not commercially impossible to prevent entirely the phenomenon in large ingots used to make the larger sizes of high-speed steel bars, and for this reason large bars do not show as refined a fracture nor as good as a microstructure as smaller sizes of the same chemical composition and heat-treatment.

Heating to about 2,200 deg. F. and holding a sufficient length of time to permit an absorption, solution or combination of these carbides, followed by an annealing, reduces the segregation somewhat, bringing about a more uniform condition, although it cannot be entirely eliminated by this method alone, nor by hardening alone from high temperatures.

A study of the casting condition of high-speed steel in ingots of various sizes seems to indicate that this "ingotism" is favored by and is largely dependent upon the casting temperature and rate of cooling. In order to show the effect of various rates of cooling upon "ingotism" formation, a portion of a 100-lb. pot or crucible of molten high-speed steel was poured into cold water, thereby producing very rapid solidification; this will be referred to as condition No. 1. Another portion was teemed into a 4 x 4-in. warm mold, the rate of cooling being less rapid, and this condition will be referred to as No. 2. The crucible, with the remainder of the steel still in a molten condition, was put back into the furnace and the gas turned off, thereby permitting it to cool slowly with the furnace. After it reached a

Fig. 8—Poured into water. Fig. 9—Poured into warm mold. Fig. 10—Quenched from pasty state. Fig. 11—Furnace cooled.

pasty condition (which required about 1 hour) some of the steel was removed and quenched in water; this will be referred to as condition No. 3. The remaining portion was permitted to solidify in the crucible, condition No. 4. It remained in a spongy or mushy state for about 1½ hours.[2]

In the condition of sample No. 1, which was quenched in water from the molten state, one will note in Fig. 8 the comparatively small size of the eutectic as compared with the primary austenitic islands. The writer believes that these islands formed first and were enlarged by the effect of undercooling. This will also be noted in Fig. 9, representing the condition of sample No. 2, but here the effect of undercooling was not as marked, therefore the eutectic is more pronounced. Such "ingotism" as exhibited in these samples is readily broken up by the forging operations.

Fig. 10, which represents the condition after permitting the steel to cool slowly to a pasty state (condition No. 3), shows the characteristic island formation of the primary austenite and the prominence of the eutectic, normally noted in the slow solidification of alloys of this nature. One will note the increase in size of the areas occupied by the eutectic and the decrease of the primary austenite as the steel passes through the rates of cooling represented by conditions 1, 2 and 3. In the latter the eutectic has more freedom to grow its characteristic star- or leaf-like structure.

Fig. 11 represents condition No. 4, when the steel was allowed to solidify in the crucible, it being in a spongy state for about 1½ hours. No undercooling is in evidence, and the relative proportions of eutectic to primary austenite can probably be considered as normal for very slow solidification.[3]

The above experimental tests agree with the numerous commercial tests on ingots of various size and indicate that the rate of solidification plays an important part as to the prominence of "ingotism." In fact, it seems to play the largest part in crucible practice, although the initial casting temperature has a small influence for the following reasons: In order to cast the average high-speed steel successfully, the temperature should not be lower than about 2,800 deg. F., in fact, good steel is seldom poured cooler than 2,850 and various heats will average about 2,900 deg. F. The maximum temperature of large crucible furnaces is approximately 3,100 deg. F., but normally not over 3,000. Therefore the range for commercial casting does not extend much beyond 100 deg. F. and hence the initial casting temperature appears to play only a small part in the formation of "ingotism" in crucible steels. However, in the electric furnace, where higher temperatures are readily obtainable, the initial casting temperatures would have greater influence.

In order to show the effect of heat alone in breaking up this segregated condition, a sample of steel in condition No. 2 (cast in warm mold) and another in condition No. 4 (furnace cooled), as cast, was heated to 2,200 deg. F. and held at that temperature for 24 hours. Before heating, their carbides were in a condition as noted in Fig. 9 and Fig. 11, respectively. Fig. 12 shows the effect of this heating upon the condition represented by sample No. 2, and it will be noted that the eutectiform masses are entirely broken up. Such a degree of "ingotism" would have broken up more readily were this heating accomplished by mechanical work, but this experiment shows the ease of breaking up "ingotism" in the average small ingot. It will also be noted from Fig. 12 that the carbides tend to assume marked crystalline forms, especially those not lying along the border of a grain, but apparently thrown out of solution from the primary austenite. That the eutectiform carbides have great freedom when heated to a temperature such as 2,200 deg. F. can be noted by comparing the change in form from that of the ingot condition shown in Fig. 11 to what may be termed an equilibrium state as shown to the right end of Fig. 13. This figure rep-

FIG. 12—SAMPLE SHOWN IN FIG. 9 AFTER HEATING AT 2,200 DEG. F. FOR 24 HOURS. × 200

[2]In order to appreciate fully the process of solidification of high-speed steel and the formation of these carbide segregations, as well as the causes of these characteristic eutectiform masses, the reader should refer to Dr. Henry M. Howe's work on the "Metallography of Steel and Cast Iron," 1916, pages beginning 135, which describe the solidification of pure and eutectiferous alloys, and page 210 for the effect of "undercooling."

[3]The samples represented by Fig. 11 were etched in 10 per cent nitric acid rather heavily in order to show a marked contrast between the eutectic and primary austenite. It was noted during etching that the primary austenite was readily attacked by this method, and it was used as will be referred to later, in an endeavor to separate the eutectic as a "sponge" from the matrix or austenite.

resents the course which these eutectiform carbides follow upon being broken up by heat alone.

Since the photomicrographs showing these stages were all taken from one sample and assembled into a composite view, it may be noted that heating to a high temperature breaks up these eutectiform carbide masses in several stages.

Some films and masses break up sooner than others, probably depending upon the carbide saturation of the surrounding matrix. The writer believes that the first change from the ingot condition is the formation of a eutectiform mass with thin sheets of carbide and austenite alternating, shown on the left end of Fig. 13. The sheets, or arms or ribs whatever they may be called, next dissociate to form spheroidal masses, as shown near the center of the illustration. These then agglomerate to form carbide masses or islands, shown to the right of Fig. 13. It may furthermore be remarked that higher magnifications reveal small isolated crystallites occurring within the original austenitic crystals, exhibiting plane boundaries and angular edges, similar to those noted above and shown in Fig. 12.

Effect of Overheating

That the eutectiform masses, which are broken up during the combination of heat and mechanical work in commercial manufacture, are of low melting point and are the structures to which the carbides, found in normal high-speed steel, revert upon heating a bar to the point of fusion can be noted from Fig. 14. If a bar of normal high-speed steel, exhibiting the structure shown in Fig. 7, be heated to a temperature just under the fusion point and quenched in oil, the structure at 600 diameters shows fairly large austenitic grains, and in the interstices sizable masses of well-developed and clearly laminated eutectic. The "fern-leaf" carbide formations develop in steps similar to those noted in the breaking up of "ingotism" by heat alone, but vice versa. The carbide masses first appear to form spheroids, which in turn form arms of a eutectiform mass. However, the spheroidal carbides noted in Fig. 14 may have been the arms of a eutectiform mass that broke up during the subsequent slow cooling of the highly heated bar. Fig. 13 and Fig. 14 show striking similarity.

It was mentioned above that if the polished samples

FIG. 14—NORMAL HIGH-SPEED STEEL HEATED TO JUST UNDER FUSION, HELD AT THAT TEMPERATURE FOR SEVERAL HOURS AND COOLED SLOWLY. × 400

of high-speed steel which were permitted to cool slowly with the furnace from the molten state (condition No. 4), the primary austenitic islands or masses were attacked readily during etching in 10 per cent nitric acid, whereas the network of eutectiform carbides were not affected. By the use of this method the following attempt was made to determine the chemical composition of the eutectiform carbides.

Chemical Analysis of Carbides

Small pieces about $\frac{1}{2}$ in. square were ground and polished on one side, similar to preparing a sample for microscopic examination. This polished side was cut off the piece by means of a thin-friction carborundum wheel, giving a disk about $\frac{1}{16}$ in. thick. This disk was placed in a clamp with the polished side facing in. The opposite side was then ground and polished, reducing the thickness to about $\frac{1}{32}$ in. The disk was then weighed

FIG. 13—COMPOSITE VIEW OF SAMPLE SHOWN IN FIG. 11 AFTER HEATING AT 2,200 DEG. F. FOR 24 HOURS. × 350

and suspended by means of a platinum wire in a beaker containing 10 per cent nitric acid. After a period of about 240 hours all reaction appeared to end; it was dried, weighed and placed in fresh acid until no further reaction was noted and no loss of weight detected, after which it was analyzed. Results are shown in Table I.

The chemical composition of the original steel is as follows: C 1.34 per cent, Mn 0.34, P 0.020, Si 0.59, Cr 3.14, W 15.88, V 0.83.

It will be noted that the carbon content, 1.34 per cent, is much higher than is usually found in commercial high-speed steel. This was not made intentionally, but was due to the absorbtion of additional carbon from the crucible during the soaking and slow cooling.[4] Therefore the chemical composition obtained by the separation of the eutectiform carbides by the above-mentioned

TABLE I—INSOLUBLE CARBIDES FROM HIGH-SPEED STEEL

method may not be of exactly the same composition as those usually found in high-speed steel containing about 0.50 to 0.70 per cent carbon. However, the analyses may give some idea of the aproximate composition of these carbides and probably their real composition, if the elements tungsten and chromium form definite combination with carbon.

It will be noted that, although the weights of the polished disks show quite a wide variation, nevertheless the percentage of loss in weights is nearly constant, indicating that the extraction of the matrix from the sponge of carbides was practically uniform.

Table II shows the calculated composition (using the values given in Table I) of the primary austenite, or

the masses that went into solution, together with results of chemical determinations of the tungsten, chromium and vanadium contents of the solutions. A comparatively close agreement exists between the calculated values and the results of actual determination.

Only one residue or separated eutectiform mass was used for chromium and vanadium determinations. However, by using the data on hand and obtaining the iron content by difference, the approximate chemical formula of these eutectiform carbides is: $VCr_2W_{10}Fe_{22}C_9$, which figures C 3.10 per cent, W 55.90, Cr 3.31, V 1.52, Fe 36.17.

[4] That such absorption took place is evident from the fact that samples 1 and 2, that were quenched in water and teemed into a mold, respectively, show only 0.87 per cent carbon, which, too, is slightly high.

Summary

1. The composition of the eutectiform carbides examined may be represented by the formula $VCr_2W_{10}Fe_{22}C_9$ and has the following chemical composition: Carbon 3.10 per cent, tungsten 55.90, chromium 3.31, vanadium 1.52, iron 36.17, and excepting for the chromium and vanadium content is the approximate composition of ferrotungsten. The composition of the primary austenite of the specimens examined appears to be: Carbon 0.77, chromium 3.10, vanadium 0.63, tungsten 3.71.

2. These eutectiform carbides are essential factors in imparting high-speed properties.

3. When present in eutectiform mass, these eutectiform carbides produce in high-speed steel a coarse, fibrous, woody fracture in the annealed, natural or hardened states.

4. The condition mentioned in item 3 causes the steel to be difficult to anneal, to possess hard and soft spots after annealing, to tear and show bright streaks on machining, to be brittle or short even in the annealed condition, to develop cracks in hardening and to lower the cutting efficiency.

5. The condition mentioned in item 3 is favored by high casting temperature and slow cooling, hence the advisability of using ferrotungsten with its lower melting point and easy solution in the melting mass of the charge, which form of tungsten favors lower temperatures, more rapid melting and quicker cooling.

6. The condition mentioned in item 3 can be broken up best by the combination of heat and sufficient mechanical work. It cannot be entirely removed by heat alone, nor eliminated by hardening and annealing.

Pittsburgh, Pa.

Scotch Producers Combine to Push Esparto Paper

An important combine recently organized in the Scottish paper-making industry is reported in the March 6 issue of *Commerce Reports*. The new organization is to be made up of the esparto paper mills of Scotland, including eight or ten mills. There is no intention to disturb the existing organizations, the mills to continue their own individuality and their own directing board. The propaganda and the advancing of the business throughout the world generally will be handled by the board, with the assistance of the present distributing houses, which are for the most part favorably disposed. It is hoped to develop a very big business in America.

The sole idea underlying the action of the promoters of the new combine is to extend the demand for the use of esparto paper so as to enable it to be more cheaply produced. Esparto grass, which is gathered in large quantities in Africa and to a smaller extent in Spain, is said to constitute one of the best of paper-making materials, especially for those qualities of paper used in printing papers, books and magazines, as well as the qualities used in lithographic printing and art work. It is claimed that its great peculiarity is that it will not stretch, is opaque, and light in weight. It is also stated that the only place in the world where this class of paper is made is in the British Isles, chiefly in Scotland.

Shaloilogy and Oil-Shale Nomenclature

A Consideration of Some of the Inconsistencies in Present Oil-Shale Terminology—As an Aid to the Definite Expression of Ideas in This Industry the Following Are Suggested: Petrologen; Petrolo-Shales; Oil-Shale; Petroil; Shalene; Shaloilogy

By J. B. JENSON

OUR American shales and the production of oil therefrom is at present being discussed in written articles by many writers of varying experience and capacity. Some of these are recording more or less valuable results of experimental and research work, some of which is new and some already well-known facts; others are merely rehashing old and well-worn data gleaned from the records of Scotch operations and U. S. Geological Survey Bulletins.

Those of the former class are endeavoring in an honest way to contribute their quota toward the pioneering of the coming shale-oil industry, an industry which cannot help but become sooner or later one of the largest and most important within the boundary of the United States. Owing to the fact that it is in its infancy in this country and its literature somewhat limited, and owing to the further fact that it has developed without elaboration from a sort of cut-and-try method to its highest scientific development in Scotland, the nomenclature of the industry is small and some of the terms adopted are not only unscientific, but are either meaningless or convey a meaning not intended. As the industry develops, new terms will of course eventually find their way into our shale-oil lexicon, but inasmuch as important data are already being recorded and will continue to be recorded as the scientific development of the industry progresses, it is important that meaningless terms be either eliminated or substituted as early as possible by scientific terms of correct meaning, in order that the nomenclature and development of the industry may be proportionately advanced and also that present-day articles of importance may contain terms which shall not soon become obsolete to the detriment of such articles.

Bituminous Shale, Pyrobitumen and Kerogen

The term "bituminous shales" is one in common usage and quite correctly so, although the oil-making material in the shale cannot properly be termed "bitumen." [1]

The term "pyrobitumen" has been applied to that substance in oil-yielding shales which is not soluble in carbon bisulphide but which when subjected to heat will become transformed into oil.

A somewhat more popular term, "kerogen," was very properly suggested by Prof. Crumb Brown many years ago and has been used in Europe quite universally ever since, to denote "the carbonaceous matter" in Scotland's shales that gives rise to crude oil in distillation.[2]

At the time of its adoption the principal important product from Scotch shales was kerosene, and it is only natural that the term "kerogen," or "source of kerosene," should suggest itself to Prof. Brown. At the present stage of the world's development, however, kerosene as an oil product becomes of only minor importance and its source of little interest to us, while the matter to which the term is applied is of great interest and is very much more than the source of kerosene. It is the source of petroleum, the mother of kerosene and all the varied petroleum products and byproducts. If Prof. Brown had in mind to base the term on "kero" as wax, intending it to express "the source of wax or paraffine," it becomes perhaps even less appropriate. The term does not fully suggest to the mind or cover the matter referred to; it is not broad enough or deep enough and can scarcely be considered to be a satisfactory scientific and definite term, particularly when applied to our American shales, wherein the source of petroleum in its embryo condition and broadest sense is referred to.

Furthermore, our Eastern and our Western American shales, but not our Central Devonian shales, are geologically younger than the Scotch shales and their oil-making material has not reached that degree of decomposition that has been reached in the Scotch shales, giving us therefore in these not only a much different product but one compelling us also to do, in our retorts for these shales, what nature has partly done for the Scotch shales *in situ*. This to a certain extent accounts for "fluxing" and other troubles in the retorting of some of our high-grade massive shales of Utah and Colorado, and even though the term were applicable to Scotch shales, it does not follow that it is applicable to American shales.

"Oil-Shale" a Misnomer

The term "oil-shale," which suggests to the mind a shale containing oil, much as saturated sands do, is freely used not only to designate shales which do not contain oil except in mere traces but which do contain the carbonaceous material capable of producing oil, but also to designate such shales as do contain oil and from which it may be extracted, but which do not contain the material from which oil may be produced or manufactured.

We are rapidly approaching the stage of development wherein it becomes necessary to designate which class of shale is being referred to—the oil-producing shale,

[1] Bitumen. "The substances which furnish oil or tar when subjected to dry distillation." ("Shale Oils and Tars," Scheithauer, p. 19.)

"A generic term applied to native substances of variable colors, hardness and volatility, composed of hydrocarbon substances free from oxygenated bodies; sometimes associated with mineral matter, the non-mineral constituents being fusible and largely soluble in carbon disulphide. Examples: petroleum, native asphalts, native mineral waxes and asphaltites." ("Asphalts and Allied Substances," Abraham, p. 21.)

"A naturally occurring hydrocarbon complex, often associated with a mineral matrix, insoluble in water, but largely soluble in carbon disulphide, benzol, etc. Its color and hardness are variable." ("American Petroleum Industry," vol. 2, p. 853).

[2] "Shales of the Lothians," p. 143.

the oil-containing shale, or some of the intermediary shales between these.

By way of illustration: The black "warty" shale of the upper horizon in the Utah, Wyoming and Colorado fields yields only a trace of oil through solvents, but is capable of producing more than 70 gal. per ton by destructive distillation. There is no evidence of oil to the touch and none of the true petroleum odor, but on freshly breaking, the shale gives an odor peculiar to certain hydrocarbons. It contains virtually no oil, but is rich in oil-making materials.

The diatomaceous and other shales of California and similar fields contain a high percentage of oil but little or none of the oil-making material. They are oily to the touch and give forth a strong petroleum odor. Practically all of the oil in them may be extracted by solvents.

We have in the Uinta Basin an almost white or cream-colored shale which produces, through the agency of solvents, 7½ gal. of fine-grade paraffine oil; by destructive distillation 21½ gal. It therefore contains both oil-making material and free oil or possibly bitumen and in the proportion of about two to one. It is a hard, compact, dry, fine-grained shale having somewhat the appearance of a white limestone, will not soil the whitest silk handkerchief and gives absolutely no suggestion of oil, yet when ignited it burns freely and forms a ring of oil on the shale surrounding the flame, something which is not usual in other shales.

As the industry develops and the shale products come into competition with underground petroleum products, it will become necessary to designate which particular product is wanted—for instance, whether "shale gasoline" or "petroleum gasoline," if motor fuel is wanted. Terms designating this may also be used to very good advantage at this time in our research work.

Retorting vs. Carbonization of Shales

Occasionally someone speaks of the distillation of oil from shale as the "carbonizing of shale." Is it truly carbonizing shale?—i.e., "converting animal and vegetable matter into a residue of carbon by action of fire or corrosive agents."[3]

Or is it "converting to carbon by the action of fire or an acid or by any other means,"[4] such as we do in carbonizing or converting coal to coke and in connection with which industry the term seems to have originated? We are not interested in converting the oil-making material of shale to carbon or coke, but into crude oil, capable of being successfully and commercially refined into marketable products. That is done by proper distillation in a suitable retort, "a vessel in which substances are subjected to distillation or decomposition by heat,"[5] either intermittently or continuously.

Shale differs from coal in having a larger proportion of hydrogen in its composition and in not leaving coke on distillation. When heated in an air-tight retort, the hydrogen unites with the carbon so as to carry it away as gas and the residue left is not coke or carbon but ash, with a very small portion of carbon—in fact, is simply a spent shale.[6]

It would seem then that the appropriate term for this operation is not "carbonizing," but either retorting, "the act of distilling or decomposing the oil-making materials," or eduction, "the act of drawing out" the oil-making material as gases, from either oil-producing or oil-bearing shales.

Pyrolysis vs. Destructive Distillation

Another term which is not only cumbersome and unwieldy but in general quite distasteful is that of destructive distillation, a term which creates with the layman an undesirable impression, as was shown by a rural, bewhiskered "old timer" who, after listening to a paper read at one of our shale conventions, arose and said, "If you chemists and engineers would quit your 'destructive' distillation and do a little 'constructive' distillation, we would soon begin to get somewhere." Dr. W. A. Hamor, of the Mellon Institute, however, has very splendidly substituted "pyrolysis" for this term, and the new word is rapidly being adopted and already becoming quite extensively used by our chemists and engineers.

New Terms Suggested

To overcome some of the objections referred to and to express myself more definitely I adopted, 3 or 4 years ago, some terms of my own which I have used continuously ever since, particularly in my geological reports. They have been serving their purpose well and I thought little of them until recently I was favored by a visit from one of our active petroleum geologists who had observed these terms and who expressed himself as highly impressed with their importance. To quote his own words: "They are expressive and impressive. They are terms which grow on one, and continue to revolve through the mind for days after hearing them. Give them to the public and let geologists and chemists also have their use. We are just entering a nationally important industry and much is being done and much written on the subject. We need these and need them now."

From the thoughts developed by this conversation and with a desire to see not only the supremacy of American engineering and American chemistry maintained, but also, with the development of the industry, the simultaneous development of a concise, accurate and scientific American shale nomenclature, I have been prompted to present and discuss these matters. Therefore I submit, for the consideration and discussion of our American petroleum geologists and chemists, the terms which I am using and which apparently not only overcome the objections mentioned but also convey to the recipient a correct idea of what is intended.

In considering the adaptability of these terms, the first question which naturally arises is: Is the crude oil, produced by distillation of shale, a petroleum or sufficiently near such that it may come into the petroleum class? It is true that as at present produced it contains, on the average, a higher percentage of unsaturates than does most underground petroleum, but the unsaturates of petroleum from different fields also vary as widely as do some of the shale petroleums when compared with some underground petroleums.

We find also that the unsaturates of a single shale vary as widely when retorted by different methods as do those of some underground petroleum and some shale petroleum. Is it not likely, therefore, that as we shall more nearly approach the method of nature in the production of oil in our retorts, we shall more nearly

[3] "Webster's Unabridged Dictionary."
[4] "Winston's Simplified Dictionary."
[5] "Webster's Unabridged Dictionary."
[6] "Shales of the Lothians," p. 160.

approach also and eventually perhaps duplicate the oil-well products?

Notwithstanding the existence of several theories as to the origin of petroleum, I believe it is quite generally conceded by our best petroleum geologists that the major portion of our underground petroleum is the result of underground distillation of oil-making materials similar to those of our exposed shales, if indeed they be not lower lying petroliferous shales of a similar nature. Even though we might accept the inorganic theory as the source of underground petroleum, might it not also apply to the source of the oil-making material in our shales? On fractionation and subsequent treatment, we find the shale oil yields practically the same products as the underground petroleum, the slight variation probably being due in part to the short time used by us in their production from the shale as compared with that employed by nature. It would seem therefore, in the adoption of our first term—the term indicating the oil-making material—that we are fully warranted in selecting one which carries with it a suggestion of petroleum.

Petrologen

From the fact that the hydrogen and carbon, or oil-making material as contained in the shales, is the source of petroleum, I have taken from the word petroleum the first syllables "petrol" and have added the suffix "ogen," or source, to form the word "petrologen," indicating the source of petroleum, or that material which, through pyrolysis or destructive distillation, produces crude petroleum.

There are, as we know, a number of theories as to the origin of petrologen. The most important of these are the organic and sedimentary[7] and the inorganic[8] theories. Although it has not been positively established, it is reasonably certain that petrologen consists of plants, vegetable fiber, spores, algæ, etc., with smaller portions of animal matter, which were deposited at the bottom of lagoons and quiescent inland lakes, together with clays and ooze and which have been subjected under pressure, in the absence of atmospheric agents, to maceration and microbic action and have finally become a minutely disseminated but integral part of the shale strata, and which were apparently laid down during periods in Devonian, Carboniferous and early Tertiary times. The main constituents of our petrolo-shales are petrologen, iron pyrites and clay.

Petrolo-Shales

To those shales which are still in their primary, unaltered condition containing petrologen but not petroleum, and therefore are yet only a source of petroleum, I apply the term "petrolo-shales." This applies in general to the shales of Colorado, Utah, Wyoming, New Brunswick, the Devonian shales of Kentucky, etc.

Oil-Shales

To those which were originally petrolo-shales, but which, through later earth heat, have given up their petrologen and then through absorption have taken up the resultant petroleum and are now saturated or true oil-shales and to those shales which were originally not petrolo-shales, but which through capillary attraction or otherwise have taken up migratory oils and therefore also contain oil, I retain the term "oil-shales."

Petroil

Inasmuch as shale oil and underground petroleum resemble each other closely in source and characteristics and will shortly be converted into competitive products, it is desirable and highly important that we have for shale oil a term which not only suggests similarity and relationship to underground petroleum but which also maintains a marked distinction between the two products.

I have endeavored to accomplish this by the adoption of the Latin "petro" (rock) as in petroleum, and the substitution of our own word "oil" for the Latin term "oleum," obtaining thereby the very simple term "petroil," which has both the distinguishing feature and the correct meaning, "rock-oil." I am aware that this word is somewhat similar to the European term "petrol" but with the accent in one case on the first syllable and in the other on the last syllable, together with the very wide distinction between the application of the two words, this, it seems, should not be an important objection and the similarity is no greater than is the case in many other instances.

Shalene

To distinguish the product from "petroil" which corresponds to the gasoline fraction from petroleum, I add to the word "shale" the letters "ne" to form the word "shalene."

Shaloilogy

To indicate the science relating to the oil-making materials, oil-bearing and oil-producing shales, rocks, etc., as well as the products derived therefrom, their extraction or production, I combine the word shale, after having dropped the final "e," with the letters "oi" from oil and add the combining term "logy" to form the word "shaloilogy."

Summary

The concise terms thus developed may be summarized and defined as follows:

Petro'ogen.—A bituminous substance contained in petrolo-shales, coal, peat and other materials, which when subjected to pyrolysis in the absence of air produces a crude form of petroleum termed petroil; a sedimentary yellowish gray or brownish substance, being the remains of innumerable minute accretions and accumulations of vegetable fiber, algæ, spores, etc., frequently with small proportions of marine animal remains, originally deposited under water on the bottom of lakes and lagoons in Devonian, Carboniferous and Tertiary times and subjected to pressure, maceration and microbic action free from atmospheric conditions and being preserved, compressed into and becoming an integral part of the clay strata forming our present-day petrolo-shales.

Petrolo-Shales.—When pure, a fine-grained, gritless, argillaceous, sedimentary, underwater deposit, ranging in thickness from a fraction of an inch to many feet, containing petrologen and disseminated iron pyrites usually of microscopical fineness; that class of bituminous shale which is still in its primary unaltered, unretorted, unmetamorphosed condition and therefore contains petrologen but not petroleum or petroil, but

[7] "The New Oil-Shales Industry of the Western Slope," by the author, p. 2.
[8] "Kerosene Oil-Shales," by Karne, p. 64.

which when subjected to pyrolysis in a closed retort or otherwise in the absence of air is capable of yielding petroil. Impurities are lime and quartz, with petrologen decreasing proportionately as these impurities increase.

Oil-Shale.—An argillaceous or diatomaceous, porous, laminated or massive sedimentary or other mineral accumulation containing, through absorption or capillary attraction, petroleum, bitumen or other residual petroleum, resulting either from formerly contained petrologen or migratory petroleum and from which petroil may be extracted through the agency of solvents or by simple distillation but not requiring pyrolysis.

Petroil.—A term used in contradistinction to the term "petroleum" as applied to free-flowing underground petroleum obtained naturally from oil wells, and designating a crude petroleum obtained through the pyrolysis of petrologen, pyrobitumen or oil-making matter contained in petrolo-shales, peat, coal, etc., and capable of being fractionated and refined into products quite similar to those of petroleum. The product obtained through digestion by solvents, distillation or pyrolysis of the oil, bitumen or other oil-yielding materials in such substances as oil-shales, oil-sands, etc.

Shalene.—That fraction distilled from petroil which corresponds to the "gasoline" or "motor spirit" fraction distilled from underground petroleum.

Shaloilogy.—The science which treats of the nature and formation of the crude materials found in nature, such as petrolo-shales, oil-shales, oil-sands, peat and other bituminous matter or materials, from which petroil may be either extracted or produced through the agency of solvents, distillation or pyrolysis. The science which treats of the digestion treatment by solvents, distilling or retorting of bituminous or petroliferous materials in the production of petroil and all its varied products and byproducts.

Salt Lake City, Utah.

The Oil Industry in Russia Under Bolshevik Régime

All available data indicate that the exploitation of the Baku region as a whole has not nearly reached its full scope of development, according to an article appearing in *Commerce Reports* of Jan. 9, 1922. Only the upper horizons have thus far been worked, while the richer deposits contained in the lower strata are yet to be tapped.

The production of oil in Russia is distributed very unevenly among the principal regions of Baku and Grozny in the Caucasus and the secondary areas in the Emba region of the Urals—Turkestan, Maikop, Vosnesenk and Tsheleken. The four principal fields of the Baku region—Balakhna, Sabunchi, Romany and B. B. Eybat—cover an area of 2,978 acres. The newer fields of Surahany, Benagady, Atashka, Holy Island, etc., cover a far more extensive area, not so far fully delimited by geological surveys.

The total production of the Baku region in the last pre-war year (1913) amounted to 7,532,000 tons, or an average of about 628,000 tons per month. Its productivity for the three pre-Bolshevik years were: 1914, 6,840,300 tons; 1915, 7,267,700 tons; 1916, 7,691,900 tons.

For the period March to July, 1918—i.e., for the period of the first Bolshevik occupancy of the region—the production averaged 279,000 tons, as against the monthly average of 440,000 tons for the first 2 months of the same year.

During August and the first half of September the Baku region was controlled by a new government—namely, the "Dictatorship of the Central Committee of the Caspian Naval Fleet." Under the "dictatorship" the output was, in August, 181,000 tons, and from Sept. 1 to 15, 92,000 tons. After Sept. 15 production stopped completely and the properties were ransacked and burned, a large number of the workmen being killed. On Oct. 10 the oil industry was denationalized by the Azerbajan Government, which occupied the Baku region with the aid of the Turks, and the properties were restored to their former owners. The owners proceeded with the task of rehabilitating the industry. They managed to get up a production of 150,000 to 160,000 tons per month for October, November and December, 1918, and an average of 300,000 tons per month for the year 1919. This average was maintained up to April 27, 1920, when Baku was occupied, for the second time, by Bolshevik forces, and on May 28 the oil industry was again nationalized. At that time the oil industry of Baku had about recuperated, after 20 months of continuous private exploitation, from the violent perturbations of 1917-18. From that point (May 28, 1920), however, production declined steadily, the average monthly production for the first 10 months of 1921 being 205,200 tons.

There are 7,000 men employed in the fields, and for the first half of 1921 this force was augmented by 4,000 Red Army laborers. In 1916 the monthly productivity per employee, exclusive of distilleries, averaged 234 tons, which compares with 80 tons at the present time. The drilling average in 1916 was about 105 ft. per month per employee, as against 28 ft. at present. The same ratio obtains in the case of the distilleries and refineries.

The grand totals of the output of oil for the first 6 months of 1921 covering all the oil fields of European Russia, as compared with the figures for 1915 and 1920, are shown in the following table:

Month	1915 Tons	1920 Tons	1921 Tons
January	797,000	340,000	277,000
February	716,000	306,000	289,000
March	797,000	347,000	335,000
April	765,000	305,000	339,000
May	805,000	305,000	373,000
June	761,000	397,000	363,000

Cadmium Production for 1921

Figures obtained from producers by the United States Geological Survey show that the total production of metallic cadmium in 1921 was 65,101 lb., a decrease of 64,182 lb., or about 50 per cent, as compared with the production in 1920. On the other hand, the production of cadmium sulphide in 1921 amounted to 65,446 lb., an increase of 33,313 lb., or more than 100 per cent, over the production in 1920.

The value of the metallic cadmium produced was $63,799 and that of the cadmium sulphide was $71,336, making a total value of $135,135, as compared with $188,535 in 1920, a loss of 28 per cent. The average selling price of metallic cadmium in 1921 was .98c. a pound, as against $1.17 in 1920, and that of cadmium sulphide was $1.09 a pound, as against an average price of $1.16 in 1920.

A noteworthy development of the year was the extension of the use of cadmium electroplating for preventing rust.

A Neglected Electromagnetic Force

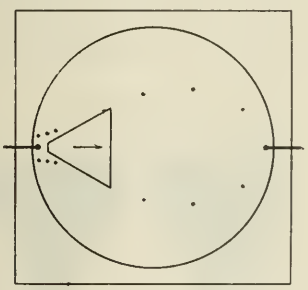
By Carl Hering

In your issue of January, 1913, p. 48, Dr. E. F. Northrup described a curious and interesting phenomenon: a kite-shaped piece of copper (well amalgamated) was floated on a trough of mercury so that its small end pointed toward one end of the trough, and its round or large end pointed toward the other end; it was found that when a very large direct current was passed through the mercury, the copper piece moved lengthwise to the trough, large end foremost; its direction of motion was independent of the direction of the current. The explanation offered by him was that the pinch effect (the radial contraction of the conductor) was greater at the smaller than at the larger end; copper having a very much better conductivity than mercury, the current was shunted largely through the copper.

In the opinion of the writer the true or primary cause of the motion is a different one, and as such new and peculiar forces may perhaps sometimes be made good use of in electric furnaces, a search for their origin and properties may be of interest, so that they may be correctly and intelligently applied.

Results of Experiments

Believing that this force was not primarily due to the pinch effect, whose force is perpendicular to the direction of the current and could therefore produce a longitudinal force only by hydraulic action, the writer floated a thick, kite-shaped piece of copper on a large circular bath of mercury about as shown in the adjoining diagram, the current being passed through the bath between the two terminals shown.



When a large direct current was used from storage batteries the copper piece made a decided but very short momentary movement toward the other pole the instant when the current was started, but the motion soon ceased; it was a mere "kick." The pinch effect was apparently very small, though if it had been the cause the motion should have continued and should not have been merely an impulse or kick.

The writer's proposed explanation is that because the magnetic flux encircling the main path of the current near the small end was more dense than that around the main path at the large end (as indicated very crudely by the dots which are supposed to represent the cross-sections of the center lines of unit lines of force) the well-known lateral repulsion of like lines of force (therefore longitudinal with the path of the current) was greater at the small end than at the large one; it is as though these lines of force acted like two compressed helical springs under unequal compression. The tendency of the mercury conductor to stretch or lengthen itself is therefore greater at one end than at the other, hence the short movement until a balance is reached.

If this is correct, an alternating current which would give a continuous rapid succession of such impulses should produce a continuous motion. When tried, it was found to do so, the piece moving very decidedly and with an apparently constant velocity across the bath to the other pole; reversing its position, it moved in the reverse direction. A counter e.m.f. must have been generated during this motion. The surface of the mercury did not show the agitation which a pinch effect would have caused, and the cross-section of the mercury was rather large for causing any marked pinch effect. The experiments were merely preliminary and somewhat crude, though apparently quite decisive. It is admitted that the pinch effect, if quite great and in a long narrow trough, would add to this force by a secondary hydraulic action, and that it would then produce continuous motion with direct current also; but the writer has shown in numerous other experiments that the same longitudinal force produced apparently by this repulsion of like lines of force acts also on solid conductors, in which of course hydraulic action cannot exist. A short piece of a well-amalgamated chain of copper links laid loosely on the mercury in a trough longer than the chain stretches itself straight when current was passed through the trough; if this motion had been due to the pinch effect at the two end links, it ought to have contracted the chain.

This Force Neglected by Physicists

This longitudinal electromagnetic force has been neglected by physicists, presumably because it happens to be zero in what appears to have been the fundamental case on which our present mathematical treatment of such forces was based, and it was thereby lost sight of.

There are two, and apparently there are only two, well-known magnetic forces which can properly be called the primary ones, at least until it can be shown that one is the resultant of the other; these are the contraction of a line of force and the mutual repulsion of like lines. A general mathematical formula should have contained both, as cases might arise like the above, and others which the writer could cite, in which these longitudinal forces do not add up to zero, or act if given the freedom to do so. Development in this field has, in the past, been checked by the fact that this longitudinal force had unfortunately been outlawed by physicists; we know that this force does exist, though in the more usual cases (but apparently not in all) it drops out because two equal and opposite forces balance each other, or because the necessary freedom of motion does not exist.

A really complete mathematical treatment ought to contain three fundamental or primary factors, instead of only one, as these forces act in space of three dimensions and the resultant in space is in the most general case dependent on all three; in most cases one or two drop out, but there seem to be some in which they do not. Referring to the flux encircling a conductor, these three directions of forces are: The usual one which is radial to the conductor, the longitudinal one (repulsion of like lines) and the tangential one (force on a unit pole).

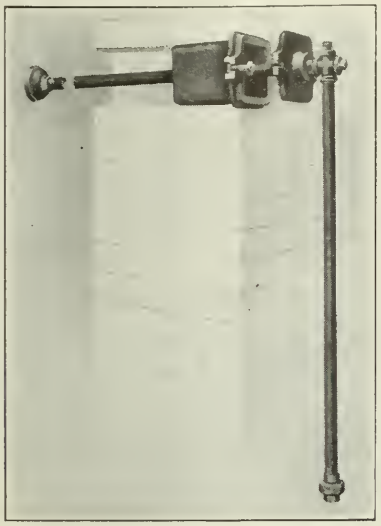
Such a complete treatment would then apply when *any* one or two are zero, for some of which cases the usual system fails.

The writer could cite experiments in which each one of these three forces is the only one, in the particular experiment, to produce the motion, the two others being inactive. There are indications that the ether acts something like a liquid with respect to these forces.

Flue Gas Filter for CO_2 Equipment

The main essential for the satisfactory operation of recording carbon dioxide equipment is cleanliness of the flue gas sample. In order to eliminate the deposition of soot in the sampling lines and the recording apparatus, the Uehling Instrument Co. has developed a filter which may be placed on the inlet end of the gas sampling line inserted in the flue or last pass of the boiler. The filter consists of a heavy but highly porous disk of refractory material which is held in a cup-shaped casting by means of a bolt.

Formerly the gas was withdrawn through an open-ended pipe and the filtering was accomplished with cot-



UEHLING FILTER FOR FLUE GASES

ton waste, this necessitating more or less frequent blowing out of the gas line and renewal of the filtering material. With the new arrangement, the soot builds up on the "Pyroporous" filter and does not appear to enter the pores to any extent—in fact some of these filters have been in service for months without having been blown out or replaced and without offering appreciably increased resistance to the gas flow.

It is not yet known what life may be expected of these filters, but present indications are that they will last for several years without attention. They are, however, inexpensive and are easily replaced. To facilitate inspection and replacement the manufacturer has also developed a frame to be inserted in the brickwork and a holder for the sampling pipe. In the illustration the holder is shown detached from the frame. It is quickly fastened in place by two bolts. By loosening the nuts on these bolts and by unscrewing the union shown at the bottom of the section of sampling line the filter may be withdrawn through the frame. The frame is the width of two bricks, hence it is a simple matter to insert it in the setting without cutting a large hole in the brickwork. When the sampling line is to be inserted through a metal casing, as with a horizontal tubular boiler, the frame is omitted and the holder is bolted directly to the metal casing of the boiler.

The filter may be used for any type of recording or testing instrument where clean gas is desired, and the frames and holders may be adapted for the installation of pyrometers, draft gages and for providing convenient openings in the furnace for test and observation purposes.

Synopsis of Recent Chemical & Metallurgical Literature

Properties of Single Crystals of Aluminum.—H. C. H. Carpenter and Miss C. F. Elam have described[1] experiments on "Crystal Growth and Recrystallization in Metals," where they demonstrated that crystals in a commercial aluminum sheet would not grow or be absorbed upon annealing if not previously overstrained. A certain amount of overstrain caused a few crystals to grow by boundary migration; a larger deformation caused recrystallization starting from a multitude of centers at former grain boundaries.

Working recently[2] with very pure cold-rolled aluminum sheet (Al 99.6 per cent, Si 0.19 per cent, Fe 0.14 per cent), test-pieces measuring 4 in. x 1 in. x $\frac{1}{8}$ in. were converted into a single crystal thus: Recrystallizing by annealing 6 hours at 550 deg. C.; stretching 1.6 per cent on 3 in. by loading at 2.4 tons per sq.in.; then heating in a furnace whose initial temperature was 450 deg. C., and raising it 20 deg. per day up to 550 deg. C., and subsequently heating 1 hour at 600 deg. C. to effect the absorption of persistent small surface crystals.

Prof. William Bragg examined some of those large crystals by his X-ray method, and confirmed not only Hull's conclusion that they are built up on a face-centered cubic lattice, but the metallographist's assumption that etching is a reliable method of distinguishing crystals in a metal. However, these crystals may be placed at any angle to the line of load, consequently the tensile properties will vary widely. Still each specimen exhibited the wedge-shaped fracture predicted by Jeffries and Archer.[3] The authors recognize five types of fractures, as shown in Table I.

A word descriptive of type 5 may be included. These produced twins in various numbers. Slip-bands change direction at these twin boundaries, and recrystallization commences here, but they are invisible in a repolished and

FIGS. 1 TO 4—TEST-BARS OF ONE CRYSTAL. FRACTURES OF VARIOUS TYPES

etched section except under oblique illumination. Some twins looked like large fibers (Fig. 4). Others showed merely a narrow straight dark line on the test-piece; they often occurred at the edges. Fig. 5 shows the plan and

[3] CHEM. & MET. ENG., vol. 24, p. 1058 (June 13, 1921).

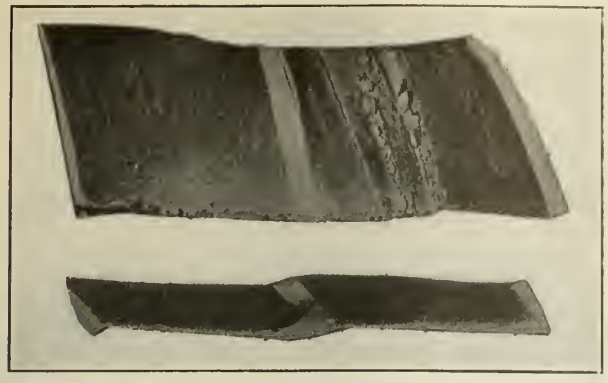

FIG. 5—SIDE VIEW AND CROSS-SECTION OF A TEST-BAR WHICH TWINNED LENGTHWISE

cross-section of one crystal which turned at the edges in opposite directions and at the center, all on parallel planes.

Many test-pieces were pulled which consisted of two abutting crystals. In no case did fracture occur at the junction; in fact, mutual support was clearly in evidence to a depth of ¼ in., leaving the boundary as a pronounced ridge.[4] If crystals existed side by side, one frequently broke before the other, and on reassembly a gap of ¼ in. was often noticed.

Round bars, 0.56 and 0.8 in. diameter, consisting of a single crystal, always flattened in one dimension as much as 45 per cent, leaving the other substantially unchanged. Fracture always occurred in a curious way; both pieces were cupped, forming a groove on reassembly.

Single crystals are remarkably malleable, remaining quite ductile after cold reduction of 93 per cent with no annealing, a property far in excess to the normal sheet. Brinell depressions made in single crystals were almost square, with rounded corners.

Carpenter and Elam conclude their paper with a brief discussion of the cause of grain growth. They have been of the opinion that mechanical deformation supplied the energy required, and heat supplied only the necessary mobility. Amorphous metal produced during deformation cannot be a store of recrystallizing energy, since maximum deformation does not correspond to maximum crystallizing power. Such questions will await the investigation of the actual changes in the space lattices of large crystals when subjected to plastic deformation, a research which is under way in collaboration with Sir William Bragg.

TABLE 1—CHARACTERISTICS OF SINGLE CRYSTALS OF ALUMINUM

Type	No. of Specimens	Characteristics	Fracture	Figure	Strength Long Tons Per Sq.In.	Elongation, Per Cent
1	7	Slips reduce breadth only	Severe necking	1*	2.9 to 3.9	57 to 67
2	7	Slips reduce thickness only	Straight knife edge	2	2.8 to 3.3	47 to 73
3	15	Slips reduce both dimensions. Cross-section becomes rhomboidal	No neck	..	2.9 to 4.08	34 to 86
4	8	Like type 3, but necks	Local neck	3	3.1 to 3.8	53 to 79
5	5	Develops mechanical twins	Various	4	3.0 to 3.8	55 to 67
Normal	5	Sheet as received, but reheated 6 hr. at 550 deg. C. About 150 crystals to the linear inch	Slight neck	..	4.5 to 4.7	36 to 38

*Some of the specimens were lightly ruled in squares before testing.

Importance of Time in Heat-Treatment of Chromium Steel.—Notwithstanding the general understanding that temperature control is essential to correct heat-treatment, direct attention is seldom given to the no less important factor of time, Prof. C. A. Edwards pointed out at a recent meeting of the British Institute of Metals in Birmingham.[1] For instance, ordinary carbon steel, suitable for files, if quenched in water will be glass hard, but if a slightly longer time be allowed for cooling between 800 and 400 deg. C. it will be very soft. Hence the impossibility of deep hardening massive pieces of such steel—it is impossible to quench the underlying metal at a sufficient rate—and the use of alloyings elements such as Ni, Cr, W or Mn, which act on hardness in the same direction as rapid cooling. However, many special steels are no less sensitive to the time at heat than high-carbon steel. For instance, a steel containing 0.33 per cent C, 3.1 per cent Ni, and 1.6 Cr, will exhibit markedly different cooling curves and different strength and hardness as it is cooled even at the same rate from varying temperatures between 814 and 874 deg. C. Again, chromium steels are sensitive or not depending upon whether the ratio between chromium and carbon exceeds 10 to 1. If there is more than enough chromium to satisfy the carbon as Cr_2C_2, then the steels no longer act as plain carbon steels, and the initial temperature of quenching ceases to have influence on their critical cooling velocities. A sample of 0.4 C. steel having 12 per cent chromium requires a cooling rate of more than 60 minutes to permit the transformation to progress. High-carbon, high-chromium steels (like 1.2 per cent C, 10 per cent Cr) will exhibit increasing hardness as the quenching temperature rises to 1,000 deg. C., but decreasing hardness when quenched higher. Thus its Brinnell hardness is about the same when annealed and when quenched from 1,200 deg. C. This is somewhat misleading, however, for, like high-manganese steels, they cannot be machined. Also "tempering" at 600 deg. C. or higher greatly increases the hardness.

[4]It is somewhat surprising that the normal specimens have such moderate strength in comparison with that of crystals 2,000,000 times as big, in view of the undoubted aid given by adjacent crystals.

Recent Chemical & Metallurgical Patents

British Patents

For complete specifications of any British patent apply to the Superintendent, British Patent Office, Southampton Buildings, Chancery Lane, London, England.

Artificial Silk.—Brilliant threads of viscose silk are obtained if the freshly precipitated gelatinous threads spun in a sulphuric or other acid bath are wound up on spools, etc., in a solution of ammonium chloride or sulphate. The ammonium salt bath is maintained neutral or of the desired degree of acidity by the addition of aqueous ammonia or acid. The viscose may be in the fresh or ripened condition, and it is preferred to employ concentrated solutions. (Br. Pat. 171,776. Technochemia Akt. Ges., Glarus, Switzerland. Jan. 11, 1922.)

Sodium Cyanide.—Sodium cyanide is produced by the action of nitrogen on a mixture of sodium carbonate and carbon, the latter being preferably in large excess. To prevent the destruction of the cyanide through contact with the other reaction products, the furnace is provided with a pervious hearth through which the reaction products are withdrawn, while the furnace space is filled, for the most part, with reducing gases which are burned in the upper part of the furnace. The furnace hearth may consist of hollow iron plates stood on edge, through which water or cold gases are passed to cool the reaction products. If necessary, the water or other cooling medium may be injected into the reaction products to produce ammonia and soda, the latter being returned to the furnace. (Br. Pat. 172,027; not yet accepted. H. Mehner, Berlin. Jan. 18, 1922.)

Decolorizing Liquids.—Sugar solutions and other liquids are decolorized by the use of an adsorbent and a reducing agent in conjunction. The reducing agent may be applied first, or some adsorbent may be applied first and filtered off and the reducing agent may be applied, followed by more adsorbent, or the adsorbent may be allowed to remain in

[1]Reported in the *Iron and Coal Trades Review*, Jan. 27, 1922, p. 121.

contact with the material while the reducing agent is applied. Examples are given of the treatment of sugar solution with bone charcoal and sodium hydrosulphite. Sulphur dioxide may also be employed. (Br. Pat. 172,272; not yet accepted. J. F. Straatman, Holland. Jan. 25, 1922.)

Soaps and Fatty Acids.—A process for deodorizing liquid soaps containing water or converting fatty acids with several double bonds into homologs of oleic acid consists in forcing the substance under pressure through a pipe heated to about 250 deg. C. The heating may take place in two stages, in which case the second portion of the pipe may be heated up to 300 deg. C., and further quantities of alkali may be added by means of a separate pipe before the second stage is reached. A suitable pressure is 70 atmospheres. (Br. Pat. 172,250. Henkel et Cie., Dusseldorf. Jan. 25, 1922.)

Book Reviews

THE CHEMICAL AND METALLOGRAPHIC EXAMINATION OF IRON, STEEL AND BRASS. By *Wm. T. Hall* and *Robert S. Williams*. New York: McGraw-Hill Book Co., Inc. 502 pp., 183 illustrations. Price $5.

About two-thirds of this volume is taken up with methods of chemical analysis, and the remaining third with metallography. The former portion is the more valuable. Various methods for the analysis of all possible constituents of iron and steel are not only given in detail as to procedure, but are also explained in principle or theory, and the different methods for the determination of a given element are compared and criticized in an interesting way. Quoting from the introduction, the book "is written more from the point of view of the educator than from that of the busy analyst," and not "for the chemical laborer so much as for the man who wants to know and to understand methods of chemical analysis." Judged from this point of view, the book is certainly a success as applied to iron and steel, and few adverse criticisms of that portion can be made. A serious omission is that of any method for the determination of alumina or of total non-metallic inclusions in steel. The table of oxygen contents of various steels on page 257 would be much more interesting to a metallurgist if more data had been given on the history of the samples during manufacture. But it is plain throughout the book that it is written by, and intended for, chemists, rather than metallurgists.

The chapter on electrometric methods is excellent, with its brief explanation of electrical terms and electrolytic theory. One of the best points about the book is the stress laid throughout upon the importance of proper sampling in order that an analysis may be of value. This certainly cannot be emphasized too much, to those who use as well as those who make chemical analyses, and the troubles arising from segregation and other non-uniformity of materials are well brought out by the authors.

The non-ferrous chapter is brief and rather peculiarly arranged, and evidently was considered of secondary importance. Methods for the determination of copper, tin, zinc, lead, phosphorus, nickel, arsenic, antimony, etc., are given, but there is no mention of the rapid method for deposition of copper by means of a solenoid for rotating the solution as advised by Frary, instead of by use of a rotating anode. Neither is any method given for the determination of sulphur in bronze. A glaring error is the wrong definition of manganese bronze on page 307. Theoretically perhaps this term *should* denote a "copper-tin alloy to which manganese has been added," but practically what is now called manganese bronze is an impure copper-zinc alloy, and it would seem that a book of this kind should recognize facts as they are, even though it might be necessary to explain that the name as commonly used is illogical and should eventually be discontinued. In this as in several other places in the book it appears that the authors are just a trifle out of touch with the practical applications of metallurgy, so that their ventures into this realm are not always wholly successful.

Part II, or the final third of the book, dealing with metallography, is plainly written from a chemist's viewpoint, and does not go into the subject very deeply. The method of preparing specimens is outlined, with some useful notes on the microscope and photography, but the usual textbook fallacy in regard to the necessity for color-sensitive plates in non-ferrous work is repeated. In certain instances such plates may be an advantage, but those instances occur just as often with iron and steel as with copper alloys, and the vast majority of work with all kinds of metal can be recorded with perfect satisfaction on ordinary process plates, provided some intelligence is used in printing as well as negative-making.

Excellent discussions are given of the iron-carbon diagram, metallographic constituents, and segregation. It is unfortunate, however, that segregated spots are stated to include oxides, for this is extremely doubtful and certainly not demonstrable by the microscope, which shows them only in *decarbonized* areas. Macroscopic methods of investigation are described, including the making of sulphur prints, but the latter process, while correct in principle, is not given in a specially practical manner, and would appear to have been described by some one who had not made very many of these prints successfully.

A chapter on the general study of steel with the microscope indicates some of the ways in which this work might be useful to the chemist, or as supplementing the chemist's report, and two very good chapters follow on the structural features of cast iron. Sampling is discussed in detail in another chapter, and magnetic and X-ray testing are briefly described. It is hard to see why they should be given under "Sampling," however.

The final chapter, on non-ferrous metallography, is good on the whole, though rather brief on all phases of this subject except the brasses. A few rather serious errors and omissions occur, however, in this chapter, and a revision of certain parts would be decidedly beneficial. The discussion of beta brass and Muntz metal on page 455 does not agree very well with that on page 467, and the careful reader who might be attempting his first study of the subject from these pages could scarcely fail to be confused by them. The trouble is that it is not explained on page 455 that true equilibrium as represented by the copper-zinc diagram is probably never attained in this alloy under practical conditions, so that both pure beta and alpha plus beta structures are often found in the commercial alloy, whether quenched or cooled slowly. The conditions here are quite different from those met with in bronze, as described on page 456, where it is difficult to retain beta below the transformation temperature. The important delta constituent of bronze is not discussed at all, though its occurrence and distribution are among the most important points to be determined in metallographic work on this alloy. The statement that copper alloys may contain copper oxide is erroneous, as this oxide is found only in the pure metal, and all ordinary alloying elements promptly reduce it, becoming oxidized themselves instead. The bad effect of oxide on conductivity is also a fallacy, as it has less effect in this way than almost any other impurity in copper except lead.

Thus in general it may be said that the chemical part of this book is an excellent and interesting guide to the thoughtful analyst, while the metallographic part is not quite so good. Of course it could not be expected that in a book two-thirds devoted to chemistry the subject of metallography would be thoroughly covered, but on the other hand it is disappointing to note so many errors that might have been avoided by a little more care.

Steel-works chemists using this book could scarcely fail to find it a help in their analytical work, and if they wished to take up metallographic investigations, as the authors very sensibly advise, they would undoubtedly get a fair start from it along this line. But it would not be long before they would find problems in manipulation to be solved by personal experience, and other problems on which the help of a more advanced text would be required. To the worker in non-ferrous metals exclusively the book is not to be recommended, as there are other books available that cover this branch of the subject more completely.

GEORGE F. COMSTOCK.

Technical News of the Week

Current Events in the Chemical, Metallurgical and Allied Industrial Fields—Legislative Developments—Activities of Government Bureaus, Technical Societies and Trade Associations

Muscle Shoals Developments Lag in House and Crowded Out by Treaty Interest in Senate

Some time is expected to elapse before any important step is taken by Congress in the pending negotiations involving the Muscle Shoals project. The Senate, in the throes of the treaty fight and about to take up tariff legislation, is having difficulty finding the time to give consideration to so intricate a matter as the disposal of the plants and waterpower at Muscle Shoals. The Senate Committee on Agriculture will probably not be able to visit the plant until the latter part of March. Fifty Senators have indicated their desire to investigate the plant.

Several efforts have been made in the House to bring its hearings to a close. The ramifications of the proposal, however, have made it impossible to carry those plans through, with the result that the record is assuming formidable length. No proposition before the Military Affairs Committee of the House has enough strength to make it advisable to press the proposition for an early vote in committee. The friends of the Ford offer believe that delay will work in their favor in that the desires of the public will be manifested anew when the results of the hearing are summed up. They believe this will bring into their ranks two or three members of the committee who still are non-committal. On the other hand, the opponents of the Ford offer think they will gain by any delay. As a result there is no great pressure for a prompt report on the matter. Chairman Kahn of the House Military Committee has introduced a resolution in the House authorizing that committee to visit the plant for investigation.

Senator Culberson of Texas has announced that he favors the sale or lease of the plant to Henry Ford.

During a Senate debate on the subject, Senator Norris of Nebraska, chairman of the Agricultural Committee, which is considering the various lease offers, said he was drafting a bill which he will introduce in the Senate providing for government operation of the plant. While he has not made up his mind as to the value of the various offers for lease, he said the Senate should seriously consider the possibility of government operation in view of the large expenditure heretofore made on the plant by the government. He favors independence from foreign fertilizer materials and from the fertilizer trust alleged to exist in the United States.

Senator Heflin of Alabama favors acceptance of the Ford lease offer. Senator McNary of Oregon said serious consideration should be given to all lease offers, and expressed a desire to know if the Alabama plant could compete with the Niagara Falls nitrate plant. Senator Smith said there should be no quibbling over the various offers, but the matter should be decided in the light of benefit to agriculture. Senator McNary said Ford's offer should not be accepted until every offer had been studied. Senator McKellar of Tennessee favored the Ford offer and referred to the phosphate available in the South.

Appropriation Announced for Bureau of Chemistry

The House Committee on Appropriations, in reporting the bill carrying funds for the Department of Agriculture for next year, provides $1,267,631 for the Bureau of Chemistry, which is $32,620 less than appropriations for the current year and $7,080 less than the estimates.

Swedish Fertilizer Workers Strike

Socialdemokraten reports that the workers at the Stockholm phosphate mills have struck. This means that workers at all the fertilizer works in Sweden, totaling 1,200 hands, are striking.

McGraw-Hill Company Purchases "Mining and Scientific Press"

The McGraw-Hill Co., Inc., publisher of CHEMICAL & METALLURGICAL ENGINEERING, has purchased the *Mining and Scientific Press* of San Francisco and on April 1 will consolidate it with the *Engineering and Mining Journal* under the name of *Engineering and Mining Journal-Press*. These two publications are the leading magazines of the metal mining industry, the *Journal* having been established in 1866 and the *Press* in 1860. J. E. Spurr, editor of the *Journal*, will be editor of the combined weekly, while T. A. Rickard, editor of the *Press*, will be contributing editor, keeping his residence in San Francisco and representing, in particular, the coast and Western viewpoints. The combined publication will be issued in New York.

Secretary of Interior Urges Government Aid in Development of Western Potash Fields

Development of potash deposits on public lands in the West under more liberal leasing laws or under a government revolving fund is recommended by Secretary of Interior Fall. He believes that potash deposits exist in sufficient quantities in the Western country to "relieve us of the monopoly existing at present under the control of Germany, which furnishes to our people practically all the potash which we use in America." He recommends that Congress either liberalize the law so that private capital may be attracted to the development of the fields or provide a revolving fund to be used by some government department in prospecting for mineral deposits. The result of such prospecting would enable operation under the second provision of the leasing law and permit the government to sell or lease lands in the potash and phosphate fields upon bonus and royalty and surface rental basis.

The House Committee on Appropriations, in reporting the bill carrying funds for the Department of Agriculture for next year, recommends $70,000 for the Bureau of Soils for exploration and investigation of methods of obtaining potash, nitrates, etc.

To Investigate Foreign Chemical Markets

Director Klein of the Bureau of Foreign and Domestic Commerce recently requested of the House Appropriations Committee funds for investigations of chemicals. He said the chemical industry was considerably stimulated in this country during the war, especially in the manufacture of heavy industrial chemicals, and the bureau desired to study the possible markets in new industries in Latin America for chemicals.

In the manufacture of soap, for example, there is a considerable market to be found for caustic soda and other commodities where a market did not exist before the war. The bureau is anxious to find markets and see that American chemicals are placed there. He said there would be a demand for these chemicals for new industrial activity in Latin America.

British Imports of German Dyestuffs

In reply to a question in the House of Commons, Hildon Young stated that the total weight of dyestuffs received by Great Britain from Germany by way of reparation up to Dec. 31 last was 4,070 tons, of which approximately £570,000, or £140 per ton, was credited to Germany. Two thousand four hundred tons had been sold for approximately £228 a ton, which represented the values ruling at the date of the sale.

Chemical Industry in the Tropics Subject at New York Section, A.C.S., Meeting

The spicy tang of the Oriental tropics pervaded Rumford Hall at the meeting of the New York Section of the American Chemical Society on March 10, when two interesting papers, illustrated with attractive stereopticon slides, were presented on the place of the chemical industry in the tropics. R. F. Bacon of New York spoke on "The Tropics as a Source of Chemical Raw Materials." Dr. Bacon spent 5 years in the Eastern tropics and is familiar with the present applications and the undeveloped possibilities of tropical products. He pointed out that the field of the industrial chemist is in working up processes for making the tropical natural products more transportable and more available for consumption in the temperate countries. He described the industry built up around the coconut palm, including the drying of the copra, the collection of the sap and the extraction of the oil. The wonderfully rapid growth of vegetation suggests the development of tropical woods and grasses for paper manufacture. The prolific yield of tropical soil suggests the cultivation of casaba as a logical source of starch. The speaker predicted a steady increase in the amount of oils that will be imported from the tropics, due to the flexibility afforded consumers by newly developed hydrogenation processes. He also voiced the opinion that some of the effort now directed toward the perfection of synthetic methods might be more profitably turned to the development of the tropical sources of the natural products. The slides included photographs of the cultivation and harvesting of essential oil-bearing plants, rubber, cloves, etc., and the extraction of perfumes and oils from the plants in native distilleries.

"A Unique Alcohol Industry and a New Source of Sucrose" was the subject of the paper presented by H. D. Gibbs of E. I. du Pont de Nemours & Co. Dr. Gibbs discussed the occurrence and extraction of sugar in different varieties of palm trees and described the sugar industry that has been developed in the Phillipines using this source of supply. The nipa, coconut, sugar and fish-tail palms are the best sources of sugar among the palms, but the nipa is the only one commercially important in the Philippines. It grows in swampy land along the rivers. The sap is obtained by cutting the flower stalk and hanging a small bamboo joint under it. It is necessary to cut a slice from the end twice each day to maintain a steady flow of sap. The average yield is about 43 liters per season per plant, the plants maintaining this production without decrease for as long as 50 years. The yield can be doubled by scientific cultivation and harvesting methods. The nipa palm is the source of 90 per cent of the alcohol produced in the Philippines, and at its price of 2 cents a liter is probably the cheapest raw material known. It is not suitable for sugar manufacture, however, since it is contaminated with yeasts. The sap contains about 15 per cent sucrose. Among the slides shown were photographs of the native distilleries and nipa palm plantations. Several very interesting photographs of different varieties of palm trees taken with infra-red light rays were shown.

New Bulletin on Carbon Monoxide Poisoning

Carbon monoxide poisoning is discussed by Dr. Alice Hamilton of the Bureau of Labor Statistics in Bulletin 291 of that bureau. This publication gives a full technical discussion of the symptoms and causes of both acute and chronic poisoning and points out many industrial sources of carbon monoxide gas where danger to operatives is met. Not only safety engineers of corporations, but also those generally responsible for plant conditions will find much of value in this publication. It can be obtained direct from the Bureau of Labor Statistics, Washington, D. C.

Industrial Chemical Exhibit at Union College

An exhibition covering products and processes of practically all industrial applications of chemistry will be given in the Butterfield chemistry building by the Union College Chemical Society of Schenectady. The exhibition will be opened April 6 and will continue for a three-day period.

Third Week of Dye Investigation Brings No Substantiation of Monopoly Charges

No one of the accusations which have been made against the domestic organic chemical industries has been substantiated. At the time of this writing, the hearing before the Senate sub-committee is in its third week. The charges that have been made are numerous. In nearly every case they go back to some previous public record, but the proof which the original accusation lacked is still wanting. No consumer of dyes has come forward to testify that there is a monopoly or that efforts are afoot to consummate a monopoly. No small producer of dye materials has been brought forward to testify as to efforts to gobble him up.

There is abundant evidence that the instigators of the investigation are likely to suffer more as a result of its disclosures than are those whom they accuse. It is quite apparent that the representatives of the organic chemical industries have made a very favorable impression on Senator Shortridge, the chairman of the sub-committee conducting the probe.

Francis P. Garvan, president of the Chemical Foundation, was able in the course of his extended testimony to explain away many of the fanciful accumulations of accusations which had been brought against the industry. He feels, in the light of the information which he has given the committee, that the tissue of charges brought by Senator King have been discounted. Senator Moses of New Hampshire, who long has been active in laying much wrong-doing at the door of the domestic dye-manufacturing industry, has contributed nothing to disclose these iniquities. He has attended none of the hearings and as this is written is away from Washington.

Chemical Industries Profit by Opportunity to Present Viewpoint

The representatives of the chemical industries in attendance at the hearings are more than satisfied with the way things are working out. They point out that this is the first time the chemical manufacturers have had an opportunity to present their side of the case. Such defense as they have been able to make before Congress has been as an incident to the tariff hearings. The very nature of those hearings was such as to preclude any thorough defense such as now is possible before the Shortridge committee.

From a textile source somes the opinion that the whole investigation really has had its inspiration in the dye industry and that the hearing was timed carefully so as to enable the dye people to obtain wide discussion of their arguments for an embargo at the time the Finance Committee is whipping the tariff bill into final shape. If such were the case, it would necessarily imply collusion with Senator Thomas, Senator King and Senator Moses, who have been consistently working for more than 2 years to secure the investigation. In chemical circles it is pointed out that at least some of the accusers of the dye interests suddenly lost their enthusiasm when the Senate adopted Senator Frelinghuysen's amendment broadening the scope of the investigation so as to include an investigation of the practices of dye importers.

When the investigation reaches the point where the activities of the importers are to be considered, a sensational disclosure is said to be in prospect.

Garvan Concludes Testimony in Defence of Chemical Foundation

Mr. Garvan concludes his extensive testimony in defense of the dye manufacturers and the Chemical Foundation, declaring that he had given a complete answer to all the charges made by Senator King. He expressed willingness to answer any questions that may be asked by Senators King and Moses, who will be invited to cross-examine him. In the course of his testimony, Mr. Garvan expressed the belief that the decision of the sub-committee to place all witnesses under oath drove to cover those who have been conducting a whispering campaign to prevent the development of the American dye industry. Witnesses hostile to

development of the American industry, if required under oath to give the source of information contained in their statements, would show by their answers that their information originated with supporters of the German chemical cartel, he declared.

The Chemical Foundation, far from being the powerful, wealthy organization alleged by its enemies, has expended all of its income and part of its capital in the public interest, to educate American public opinion to the necessity of developing the science of chemistry, stated the witness.

Says Tariff Cannot Protect Dye Industry as Embargo Can

Senator Sterling brought up the question of tariff by inquiring why a high tariff could not protect the American dye industry as well as an embargo.

"No tariff can be high enough because no price is too high for Germany to pay to destroy the American industry," responded Mr. Garvan, and continuing, he declared that Germany is willing to pay any price, even to the extent of giving away its dyes plus a bonus for using them, in order to destroy the American industry. The embargo, he explained, makes it possible to keep out foreign dyes which are manufactured here satisfactorily, whereas Germany would crash through any tariff wall regardless of expense. "She wants to regain commercial domination. She wants to regain military control of the world," he concluded dramatically.

In answer to Senator Sterling's inquiry as to how reasonable American prices are, the witness replied that competition among American producers during the time they have been protected by government control of imports has brought prices down to the proper limits to the consumer.

Jeffcott Defends Institute and Ridicules Monopoly Charges

Declaring that "intensive, bitter, cut-throat competition" exists today in the American dye industry instead of the monopoly charged by Senators Moses and King, R. C. Jeffcott, president of the American Dyes Institute, challenged and denied most of the charges made by King. Mr. Jeffcott is president of the Calco Chemical Co. and is the first dye manufacturer to be heard by the committee.

In defending the American Dyes Institute against the charges that it is the center of a dye monopoly in the United States and that it has expended money for insidious propaganda and improper lobbying in connection with legislation for the complete protection of the dye industry, Mr. Jeffcott went into some detail as to the individual members of the Institute and the various expenditures. The charge that the large dye manufacturers meet to arrange and agree as to prices, through the Institute, was emphatically denied by Mr. Jeffcott.

Contrasting the alleged monopoly with the condition which he claims actually exists, Mr. Jeffcott declared the manufacturers appear to be so suspicious of one another that they not only refuse to give statistics concerning their business but will not work together to the extent called for by the present situation. He also stated that prices of American dyes are down to pre-war levels and some products are being sold under cost of production because of competition.

Under cross-examination by Senator Shortridge, Mr. Jeffcott was asked what is necessary to protect the American industry.

"First of all," he replied, "we should have a selective embargo for 5 years, then for the ensuing 5 years protection under the highest possible tariff rates, after that the same degree of protection as is accorded to other American industry against foreign competition would be ample. The only way to make protection effective is to make it certain. We have had no feeling of security, no assurance as to how long we will have an embargo. We feel that misunderstanding on the part of Congress is solely responsible for failure to give the industry proper protection."

Mr. Jeffcott said that time is an important element in developing the American industry, as before the war there was practically no such industry. The development of the American dye industry will bring American science to the aid of industry, he predicted, with benefits of incalculable value resulting.

Textile Interests Not Opposed to Tariff

Textile interests opposed to adequate protection of the American dye industry constitute only a minority of the American textile industry, according to the testimony of Morris R. Poucher of E. I. du Pont de Nemours & Co. and chairman of the legislative committee of the American Dyes Institute. Mr. Poucher presented a summary of the activities of the legislative committee of the American Dyes Institute and also made a statement concerning the activities of importers of German dyes to prevent development of the American industry and denying certain of the testimony of Senator King of Utah before the sub-committee.

"In the final analysis there is but one question," he said, "and that is, do we want this industry in the United States, or do we not? America will answer 'Yes' and the German dye monopoly will answer 'No' and that is the sum total of the whole controversy."

Open Price Section Not Successful

Harry E. Danner, treasurer of the American Dyes Institute, described in detail the work and purposes of the open price section, which was formally abandoned in June, 1920. Mr. Danner said that when this section was organized, in 1918, only five of the sixteen companies then members of the Institute participated in the section, and that no more than twelve Institute members at the most ever participated in it.

In reply to questions from Senator Sterling, Mr. Danner said the American Dyes Institute was originally organized to have an open price section, but that the latter failed, probably because the dye industry was new and its members did not like the idea of giving information about their business. No penalty was enforced, he said, against members not participating, as membership was voluntary. The difference between those participating and those not, he said, was that those who made reports received the information exchanged, while non-participating members did not.

Textile Manufacturer Not Satisfied With Investigation

A letter severely criticizing the conduct of the sub-committee of the Senate Judiciary Committee in charge of the dye hearing was left with the sub-committee by George Deming, a Philadelphia lawyer. The letter complained, in effect, that the sub-committee has permitted representatives of the American dye industry to appear voluntarily, give their testimony and depart without adequate testimony. Senator Shortridge, through one of the stenographers at the hearing, made an unsuccessful attempt to locate Mr. Daming as soon as he ascertained the contents of the letter, which bore the typewritten signature of "John Nash McCullaugh, industrial manager, National Association of Hosiery and Underwear Manufacturers."

Senator Shortridge then publicly replied to the allegations in the letter and later announced that Mr. Deming will be invited to appear before the sub-committee, in order that he and any clients he represents may have full opportunity to present any evidence they believe of value to the inquiry now going on.

Forty Tons of Sulphur Per Day Limit Set on Smelter Stacks

In the suit of the State of Georgia against the Ducktown Sulphur, Copper & Iron Co., which seeks to restrain damages to crops by reason of discharge of sulphur gases, a stipulation has been filed in the Supreme Court by both parties under which the company agrees not to permit the escape into the air of sulphur dioxide gases which have a sulphur content of more than 40 tons a day, and to furnish the state a report as to the tonnage of ore smelted and acid made. The agreement also calls for a board of arbitration of one representative each of the state and the company to supervise operations and to ascertain damages caused to citizens by the gases.

Distributing Agencies at Fault in Fleischmann Alcohol Case

All permits for the sale of alcohol at branch plants of the Fleischmann Co., Inc., were withdrawn following an exhaustive hearing of the most important alcohol case that has come before the Bureau of Internal Revenue. The Commissioner of Internal Revenue declined to cancel the permits of the Fleischmann Co. to distill alcohol at its yeast plants at Langdon, D. C., and Peekskill, N. Y. The formal decision of the Commissioner states that the agents of the Fleischmann Co., Inc., at Philadelphia, Pa., Brooklyn, N. Y., and Bridgeport, Conn., diverted to unlawful purposes the alcohol produced by the company, and forwarded to them for distribution. There is no evidence to show that the unlawful diversion of alcohol by the agents of the Fleischmann Co., Inc., was known to the company or its officers or that such officers connived or conspired with their agents in such unlawful diversion, but it is established that the officers were negligent in the inspection of the agencies and did not use due care in supervising them.

The records kept at the distilleries of the Fleischmann Co., Inc., were found to be proper and correct and in accordance with the law.

As a result of the Fleischmann case a Treasury decision has been issued amending Sec. 58 of Article IX of Regulations 60, so as to set forth clearly the responsibility of manufacturers of alcohol who distribute their product through agencies. The new regulations place upon the manufacturer the responsibility for the conduct of a distributing agency in conformity with the law. Title to liquor in the hands of an agent remains with the manufacturer until title is transferred to a purchaser having a permit to purchase. The manufacturer must accept the risks of the business done through an agent. The agent must forward daily to the manufacturer for examination a complete report showing the details of all transactions of the agent. Each transaction must invariably be reported not later than the business day following the sale.

Industrial Developments of the Week

Paper.—The S. Y. Beach Paper Co., Seymour, Conn., is arranging for the early resumption of operations at its local mills, which have been closed down for about a year. The machinery will be overhauled and improved at once.

Ceramic.—The National Fireproofing Co., Pittsburgh, Pa., is maintaining active production at its different plants. During the month of February the company booked about twice the volume of busines as in the same month of last year.

The New Castle Brick Co., New Castle, Pa., will soon resume production at its plant. Repairs and improvements will be made to the equipment at once.

Oil.—Nine oil refineries in the El Dorado district, near Monroe, La., will resume full-time production during the next fortnight, increasing production to a basis of 25,000 bbl. per day, with employment of 3,500 men.

Rubber.—The Goodyear Tire & Rubber Co., Akron, Ohio, has increased operations at its plant at Los Angeles, Cal., to a production basis of 25,000 tires a day.

Paint.—The Prince Metallic Paint Manufacturing Co. has placed its plants at Bowmanstown and Lehigh Gap, Pa., on a full-capacity basis.

Iron and Steel.—The Carnegie Steel Co. is increasing operations at its Mingo Junction plant in the Steubenville, Ohio, district, which has been running on a 75 per cent basis.

The Tennessee Coal, Iron & Railroad Co., Birmingham, Ala., a subsidiary of the United States Steel Corp., has blown in its Alice blast furnace at the local works. Production in all departments has reached practically a 100 per cent basis, making the first complete steel plant to reach this point during the past 24 months.

The Carbon Iron & Steel Co., Parryville, Pa., is completing repairs and overhauling of equipment at its mill, preparatory to early resumption of operations.

The Cambria Steel Co. has resumed production at its open-hearth furnaces at the Johnstown, Pa., works. The company has sixteen furnaces in operation at its Franklin plant and is planning to resume manufacture at its Bessemer mills before March 25.

The Inland Steel Co., Chicago, Ill., has increased production at its East Chicago, Ind., works, adding about 1,000 men to the working force. The manufacture of steel rails has been resumed and a number of departments are operating on a 75 per cent basis, as compared with a 60 per cent schedule a few weeks ago.

The United Alloy Steel Co., Canton, Ohio, is now operating ten furnaces at its local plant and the majority of the mills are in service.

Coke.—The Century Coke Co., Brownsville, Pa., has resumed operations at part of its ovens. Other units will be placed in service at an early date.

The H. C. Frick Coke Co. has fired 700 additional ovens at its plant at Scottdale, Pa., and will place other ovens in service at an early date.

During the week of March 1, 270 additional merchant ovens in the Connellsville, Pa., section were fired.

Leather.—The Graton & Knight Co., Worcester, Mass., has increased operations at its local tanning and leather plant on a basis of 50 hours per week, giving employment to about 900 men. The factory has been working on a part-time schedule for some weeks past.

Eberle Tanning Co., Westfield, Pa., is operating under a capacity schedule at its plant for the tanning of buffalo sole leather.

The Craddock-Terry Co., Lynchburg, Va., has adopted a full-capacity schedule at its new central upper leather cutting plant, recently completed. A factory unit for the production of welts is being equipped and will be placed in service on a full manufacturing basis before the close of March.

Metals.—The New Jersey Zinc Co. is making ready to place its spiegel furnaces in operation at its Palmerton, Pa., works.

The Inspiration Copper Co., Globe, Ariz., has resumed the production of concentrates at its plant. Four sections of the plant are now in operation after a shut-down of about 9 months.

The Utah Copper Co., Salt Lake City, Utah, is arranging for the early resumption of operations at its plant.

The United Verde Extension Mining Co., Jerome, Ariz., has commenced operations at one of its reverberatory furnaces at its copper plant at Clemenceau.

The Silver King Coalition Co., Park City, Utah, is planning for the immediate operation of a new 450-ton mill now being completed. Timing-up will commence about the middle of March.

Changes in Specifications for Lubricating Oils

Certain changes in specifications for lubricating oils of various grades, which were advocated by refiners on the Pacific coast, were agreed upon at the first meeting of the recently formed Interdepartmental Petroleum Specifications Committee, held in the offices of the Bureau of Mines in Washington, D. C., Feb. 27. The changes have been submitted to the Federal Specifications Board, and it is hoped to incorporate them in the technical paper containing revised specifications for petroleum products, to be published shortly by the Bureau of Mines. The committee postponed the discussion of proposed changes in specifications for transformer oil, aviation gasoline, kerosenes and signal oil. It was decided to appoint a sub-committee on greases.

The personnel of the new committee is the same as that of the former Technical Committee of Standardization of Petroleum Specifications. The new committee, however, reports directly to the Federal Specifications Board. The revision of Bulletin 5 of the old committee, which was made last fall, has had the approval of the Federal Specifications Board, and will shortly be published in the form of two technical papers of the Bureau of Mines. Of these, Technical Paper 298 will relate to methods of testing petroleum products, and Technical Paper 305 to specifications.

British Alkali Company Reduces Wages

Notice of a reduction in the wages and holidays of chemical workers has been posted by the United Alkali Co., according to a dispatch from London. The 12½ per cent war bonus on time work and 7½ per cent on piece work are withdrawn in three stages—on March 2, April 6 and May 4. The bonus is being paid to operators, laborers and other workers. Directors of the company state that its withdrawal is justified in view of the continued depression in the volume of demand for the company's products, constantly falling prices and the decreased cost of living.

Cost of Analyses in State Laboratory

The State Department of Chemistry, Harrisburg, Pa., has compiled figures showing that the state agricultural chemists analyzed feeding stuffs, fertilizers, oils, paints and animal viscera during the past year at an average cost of $4.76 per sample. A total of 2,876 samples of such materials were analyzed in 1921. The cost per sample includes all overhead charges, as rent, light, etc., at the Harrisburg laboratories, and in comparison with the work of the department at the prevailing cost, J. W. Kellogg, chief chemist, makes a comparison with the average charge of a commercial chemist at about $20 a sample.

Personal

General Avery D. Andrews has been elected president of the Shell-Union Oil Co., San Francisco, Cal., comprising the recent merger of the Royal Dutch Shell interests and the Union Oil Co. of Delaware.

L. J. Buck has severed his connection with the National Carbon Co., a subsidiary of the Union Carbide & Carbon Corporation, and has become United States sales representative of the British America Nickel Corporation, Ltd., Ottawa, with office in the Canadian Pacific Building, New York City.

William M. Corse, general manager of the Monel Metal Products Corporation, will take active charge of the division of research extension of the National Research Council on April 1, succeeding Harrison E. Howe, now editor of the *Journal of Industrial and Engineering Chemistry*. In addition to his work for the National Research Council Mr. Corse will devote a part of his time to private consulting work.

Joseph B. Elam has been appointed secretary of the Louisiana branch of the Texas-Louisiana division of the Mid-Continent Oil and Gas Association, with headquarters at Shreveport, La.

Harmon P. Fisher has been appointed engineer with the research division of the American Petroleum Institute. He was formerly in charge of operations at the United States Government helium plant No. 3 at Petrolia, Tex., and previously was connected with the Gellert Engineering Co., Research Corporation and the Westinghouse Electric & Manufacturing Co.

W. S. Frisbie recently resigned his position as chief of the Bureau of Food, Drugs and Oil, State Department of Agriculture of Nebraska, to accept an appointment as chemist in charge of the office of co-operation, Bureau of Chemistry, Washington, D. C.

H. Stuart Hotchkiss, president of the General Rubber Co. and the United States Rubber Plantations, Inc., subsidiaries of the United States Rubber Co., New York, has been elected vice-president of the parent company in charge of overseas operations.

Clayton L. Jenks has opened an office at 2 Rector St., New York, for the practice of patent and trade-mark law. He will give special attention to chemical and mechanical inventions. Mr. Jenks was for 6 years assistant examiner in the U. S. Patent Office, organized and conducted a patent department for the Eastman Kodak Co. at Rochester, N. Y., and 5 years ago established a similar system for the Norton Co., Worcester, Mass., of which he will retain charge.

H. A. Megraw has resigned as engineer for the Kennedy-VanSaun Manufacturing & Engineering Corporation of New York to become vice-president and treasurer of the Crown Oil & Wax Co. of Baltimore, Md.

Graham L. Montgomery, mechanical engineer, joined the editorial staff of Chem. & Met. on March 1. He will devote his attention primarily to mechanical phases of the chemical and allied industries and to methods of handling materials.

J. W. Newton, assistant superintendent of the Magnolia Oil Refinery, Beaumont, Tex., gave a lecture to the engineering students of the Agricultural and Mechanical College, College Station, Tex., recently, on the subject of "Refining Petroleum." The lecture was given under the auspices of the Mid-Continent Oil and Gas Association, and was the fourth of the series.

E. G. Rippel has withdrawn from the Buffalo Foundry & Machine Co. and will take an extended rest before engaging in business again. He organized the Buffalo Foundry Co. over 21 years ago and has been largely instrumental in building up the company to its present position. He was largely responsible for the extensive company exhibits at the National Exposition of Chemical Industries and for the large advertising campaigns that characterized the company's publicity plans. Mr. Rippel is succeeded as sales manager by C. W. Pearson, assistant treasurer of the Buffalo Foundry & Machine Co. Mr. Rippel's future plans will be announced later.

L. I. Shaw has resumed his duties as assistant chief chemist of the Bureau of Mines at its Washington office. For several months Mr. Shaw has been on duty at the ceramic station of the bureau at Columbus, Ohio.

Dr. Edwin E. Slosson addressed the recent meeting arranged by the chemical committee of the Chamber of Commerce and by the American Chemical Society, at Rochester, N. Y., on "Relation of Chemistry to a Civic Community."

Charles Syer, Norfolk, Va., has been appointed manager of the new sugar refinery of the American Sugar Refining Co. at Baltimore, Md., and will take up his duties at once.

S. W. Willson of the Graham Paper Co., St. Louis, Mo., has been appointed a technical adviser of the Bureau of Standards, during the work which the bureau is doing in connection with the standardization and simplification of paper and paper products. Mr. Willson was chief of the pulp and paper division of the War Industries Board during the war.

Obituary

Captain Horace G. H. Tarr, a familiar figure in the waterworks field for the past 50 years, died at his home in Philadelphia, March 2, aged 78 years. At the time of his death he was manager of R. D. Wood & Co., manufacturers of waterworks machinery, Philadelphia, Pa. At the close of the Civil War, through which he served with the Tenth Connecticut Volunteers, Captain Tarr entered the employ of the Brooklyn (N. Y.) Water Department as an inspector of cast-iron pipe. A few years later, as receiver, he operated the Tom Gaylord plant at Newport, Ky. Later he joined the Worthington Pump Co. as salesman. From 1900 until his death he was with R. D. Wood & Co. designing, selling and supervising the erection of waterworks machinery.

John J. Vorhees, president of the Vorhees Rubber Manufacturing Co., Jersey City, N. J., died at his home in that city, Feb. 26, at the age of 75 years. He was connected with the New Jersey Car Spring & Rubber Co. for 28 years, and then organized the company of which he was head.

Market Conditions

IN CHEMICAL, METALLURGICAL AND ALLIED INDUSTRIES

A Survey of the Economic and Commercial Factors That Influence Trade in Chemicals and Related Commodities—Prevailing Prices and Market Letters From Principal Industrial Centers

Petroleum Refining in 1921

On Jan. 1, 1922, there were 303 refineries operating in the United States with a total indicated daily capacity of 1,736,725 bbl., according to the compilation of H. J. Lowe, petroleum economist of the Bureau of Mines. These figures are to be compared with 328 refineries having a daily capacity indicated at 1,714,395 bbl. on Jan. 1, 1921. Operations at the latter date were on the basis of 84 per cent of capacity and on Jan. 1, 1922, at 80 per cent.

The Geological Survey has estimated the production of crude oil in the United States for 1921 at 469,639,000 bbl. and the consumption of domestic and imported petroleum at 525,407,000 bbl. During 1921 the refineries of the United States distilled 75,325,670 bbl. of Mexican crude oil; 2,745,-015 bbl. of Mexican tops and 160,557 bbl. of Mexican crude naphtha. The run of Mexican crude exceeded that of 1920 by 19 per cent.

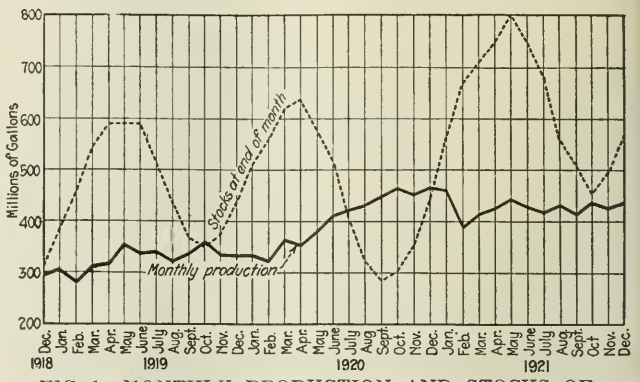

FIG 1—MONTHLY PRODUCTION AND STOCKS OF GASOLINE, 1918-1922.

TABLE I—OUTPUT BY MONTHS OF THE PETROLEUM REFINERIES IN THE UNITED STATES FOR 1921

	Run to the Stills: Crude Oil (Bbl.)	Run to the Stills: Other Oils (Bbl.)	Gasoline (Gal.)	Kerosene (Gal.)	Gas and Fuel (Gal.)	Lubricating (Gal.)	Wax (Lb.)	Coke (Tons)	Asphalt (Tons)	Miscellaneous (Gal.)	Losses (Gal.)
January	39,637,382	4,206,576	460,432,439	205,374,611	836,684,040	85,908,641	45,659,668	57,961	80,672	145,846,215	1,664,203

Total	443,362,657	36,492,565	5,153,549,318	1,945,126,156	9,663,816,135	877,859,074	433,887,214	604,465	1,214,536	1,202,433,163	19,557,517

Gasoline Production

The following figures on the production and consumption of gasoline are of interest in showing its increasing importance:

THE INCOME AND OUTGO OF GASOLINE, 1918–1921

Income	1921	1920	1919	1918
Stocks, Jan. 1	462,381,837	446,793,431	297,326,983	412,256,833
Production	5,153,549,318	4,882,546,649	3,957,857,097	3,570,312,963
Imports	37,816,004	46,066,110	8,520,169	12,899,350
Total	5,653,747,159	5,375,406,190	4.263,704,249	3,995,469,146
Outgo				
Exports	524,279,031	635,247,487	365,883,011	556,422,334
Shipments to Insular Possessions	27,368,017	21,348,911	16,217,081	12,209,957
Domestic consumption	4,516,012,979	4,256,427,955	3,434,810,726	3,129,509,872
Stocks, Dec. 31	586,087,132	462,381,837	446,793,431	297,326,983
Total	5,653,747,159	5,375,406.190	4,263,704,249	3,995,469,146

The monthly production during this period as well as the stocks on hand at the end of the month are shown graphically in Fig. 1. Maximum rate of production was reached in October and December of 1920, although the total output for the year was at its maximum in 1921.

Other petroleum products produced by American refineries in 1921 are presented in Table I. The column headed "Miscellaneous" includes the following materials and quantities:

	Gal.		Gal.
Binder	18,527,055	Pitch	129,800
Flux	27,353,495	Residue	5,786
Medicinal oils	761,008	Slops	757,125
Paint products	266,220	Tailings	180,624
Petrolatum	7,250,636	Tar	3,374,166
Road oil	125,820,652	Tops	122,267,027
Roofers' wax	66,166	Unfinished	227,446,245
Sludge products	34,672,612	Wash out	25,280
Acid oil	2,271,513	Wax tailings	3,687,074
Distillates	627,570,679		
		Total	1,202,433,163

Stocks of Gasoline

Stocks of gasoline held in storage by American refineries reached 800,495,787 gal. in May, 1921. These are said to be the largest gasoline stocks ever recorded in this country. On Dec. 31, 1921, gasoline in storage had decreased to 586,-087,132 gal., which is but little more than 10 per cent of the output for the year. Storage at the end of 1920 was 123,705,000 gal. less than that reported for the last of 1921. The domestic consumption of gasoline for 1921, however, exceeded 1920 by 260,000,000 gal. and 1919 by 1,081,000,000 gal.

The exports and shipments for 1921 amounted to a daily average of 1,511,000 gal. This figure is 283,000 gal. less than the daily average for 1921, but 463,000 gal. in excess of the corresponding figure reported for 1919.

CHEMICAL & METALLURGICAL ENGINEERING'S WEIGHTED INDEX OF CHEMICAL PRICES

Base = 100 for the year July 1, 1913, to June 30, 1914

This week	157.13
Last week	157.46
March, 1921	157
March, 1920	252
April, 1918 (high)	286
April, 1921 (low)	140

Market developments of the past week have had practically no effect on the index number, which is but one-third of a point lower than last week. The slightly increased prices for ammonium sulphate, barium chloride, caustic soda and citric acid were more than offset by the lower quotations for soda ash and crude cottonseed and linseed oils.

The Causes of Business Failures

The following figures, compiled from reports of Dun's and Bradstreet's and presented in Babson's barometer letter, afford an interesting, quantitative comparison of the different causes of business failures in 1913, 1918, 1920 and 1921:

Cause	1913 Per Cent	1918 Per Cent	1920 Per Cent	1921 Per Cent
Incompetence	18 4	26.9	13.3	22.2
Inexperience	2 0	4.7	3.3	2 9
Lack of capital	24 9	30.8	26.6	21.9
Unwise credits	16 0	1.8	3.7	3.9
Failures of others	11 4	3.3	0.8	1.8
Extravagance	0.6	0.6	0.3	0.3
Neglect	0 7	0.9	0.5	0.4
Competition	0.9	0.8	0.3	0.3
Specific conditions	14.0	19.8	45.5	42.1
Speculation	2.7	1.2	1.9	1.1
Fraud	8.4	9.2	3.8	3.1
Total	100 0	100.0	100.0	100 0
Number of failures	15,296	9,657	8,672	19,779

Business Failures in January

The largest number of business failures for any month since January, 1915, was reported in January, 1922. As we have previously averred, business mortalities are not necessarily to be regarded as an unfavorable index of future business. Rather they are the result of circumstances which have already passed and in the long run business gains by the elimination of those concerns which cannot compete successfully with the new industrial situation.

Business failures in the chemical and allied industries during January of 1920, 1921 and 1922 are compared with the 1912-13 average in the following table. It will be noted that these industries account for only a relatively small proportion of the total number of failures.

BUSINESS FAILURES IN CHEMICAL AND ALLIED INDUSTRIES

	Number of Failures in January of				Liabilities in Thousands of Dollars			
Industry	1922	1921	1920	Ave. '12-'13	1922	1921	1920	Ave. '12-'13
Chemicals and Drugs:								
Manufacturers	9	13	3	4	376	392	18	111
Dealers	64	40	10	50	715	380	66	222
Paints and oils:								
Manufacturers	1	2	..	3	83	40	...	37
Dealers	2	6	..	2	40	150	...	16
Glass and ceramics:								
Manufacturers	10	9	3	11	282	114	80	237
Total for all industries	2,723	1,895	569	1,824	73,796	52,137	7,240	20,878

Du Pont Earnings Greatly Reduced in 1921

The annual report of E. I. du Pont de Nemours & Co. for 1921 shows a net income of $5,762,417 after inventory adjustment and taxes. When dividends on the debenture stocks were deducted, this is equivalent to $2.35 per share on its outstanding common stock. This is to be compared with a net income of $14,563,232, or $16.96 a share on the common stock in 1920.

President Irenee du Pont, in his letter to the stockholders, stated that in his opinion the lower volume of business was directly attributable to the liquidation of inventories. "Of raw materials used in products sold during the first 8 months of 1921," said Mr. Dupont, "approximately one-half came out of the storehouses and one-half was purchased. This means that those who sold to the du Pont company suffered a reduction of 50 per cent in volume of materials needed by this company for its already reduced operations.

"It seems reasonable to suppose that marked reduction in buying has resulted in intense competition to sell and that this has been a large factor in the reduction of prices.

"The most lamentable result of liquidation of inventories has been the discontinuance of employment while inventories were being consumed. Your company has been obliged to discontinue the services of two-thirds of its wage earners and half of its salaried employees."

Corn Products Reports Smaller Income

The Corn Products Refining Co., during the year ended Dec. 31, 1921, earned a net income, after deduction of charges and federal taxes, of $6,326,358, equivalent, after subtracting preferred dividends, to $9.21 a share on the outstanding common stock. This compares with a net income of $12,469,626, or $21.53 a share, earned in 1920.

New York Market

NEW YORK, March 13, 1922.

The resale market during the past week did not show any signs of increased activity, but large producers have reported a good inquiry for material at the works. Caustic soda was decidedly stronger, as well as the prussiates, barium products, nitrite of soda, sal ammoniac and nitrate of soda. Imported sodium nitrite is very scarce at present and the market is apparently prepared for another sharp advance. The demand for caustic soda for March shipment has kept the market for that commodity in a very firm position. Arsenic, sulphide of soda, oxalic and citric acids have maintained their former levels and leading factors reported moderate inquiries. Caustic potash, cyanide of soda and soda ash were a trifle easier under increased importations and domestic competition.

The Commodity Markets

Barium Chloride.—Recent strength reported in the chemical was in evidence at the close of the week and it is doubtful if better than $62 per ton on spot could be done. The demand remains very good with imported offerings greatly diminished.

Bicarbonate of Soda.—Large producers have shaded regular quotations in a few instances and sales were recorded down to $1.80 per 100 lb. for barrels, f.o.b. works. Kegs were offered at 2¼c. per lb. The demand is only moderate.

Bichromate of Soda.—Dealers report small quantity business at 7¾c. per lb. Producers ask 7½c. per lb. for large lots on contract. Some of the leading tanneries have been buying recently and a still better demand is predicted.

Bleaching Powder.—Large drums are offered at 1¾c. per lb. f.o.b. works, while the imported is quoted at $1.90 per 100 lb. ex-dock. Competition still remains keen between importers and domestic producers. The demand is somewhat irregular.

Caustic Potash.—Sellers are generally quoting the 88-92 per cent at 5¾c. per lb. Some resale lots could still be bought at $5.65 per 100 lb. The demand has not shown any increased activity during the week. Shipment prices are quoted at $5.75@$6.50 per 100 lb.

Caustic Soda.—Dealers report limited offerings of March shipments for export and the market is higher at $3.65 per 100 lb. There have been some short interests in the market and this has tended to advance prices. Leading producers are of the opinion that remaining March shipments will work to a much higher level. April shipments were offered at $3.50@$3.60 per 100 lb. by dealers. Producers' quotations at the works were unchanged at $2.50 @$2.57½ per 100 lb., basis 60 per cent, for carload lots.

Citric Acid.—Prices have shown an advancing tendency, although business has been only of ordinary dimensions. Restricted production abroad has limited offerings considerably on spot and sellers were quoting 45c. per lb., duty paid.

Chlorate of Soda.—Dealers quote the imported at 6½c. per lb. Large producers are holding prices on the basis of 7c. per lb., f.o.b. works. The demand is only moderate.

Nitrite of Soda.—Higher prices are recorded for imported and domestic material and it is doubtful if better than 8½c. per lb. could be done. Producers quote this price for nearby shipments. The inquiry continues very active with supplies limited.

Oxalic Acid.—Producers report sales on the former basis of 12c. per lb. and report the demand moderately active for regular quantities. Some business has gone through on spot at 13c. per lb.

Prussiate of Potash.—Offerings of this material are not liberal and the market is holding steady at 25½@26c. per lb. on spot. The demand is fairly active from the consuming industries. Red prussiate continues nominal, with March shipments from abroad quoted at 75c. per lb.

Coal-Tar Products

Inquiries during the past week have only shown a slight improvement and have tended to place the market in an

irregular condition. Its general tone, however, appears to be toward a gradual expansion in the volume of business. Coal-tar crudes have been brought to rock bottom figures and this has caused a better demand from the consuming industry. Demand for benzene, cresylic acid, toluene and other crude products is steady and the market is being firmly sustained. There have been some recent export orders for alpha-napthylamine. The available supply of this material appears to be quite limited and very little was obtainable in the open market. Small lots of dimethyl-aniline were in good demand. Offerings of para-toluidine appeared slightly firmer. Aniline oil is showing a better tone with a moderate improvement from consuming channels. Producers report a lower market for H acid.

Benzene.—There has been no let-up from the firm position of this crude. The demand continues active both on domestic and foreign account and producers report a heavily sold condition. Resale lots are very scarce and the market is nominally quoted at 35c. per gal. for the 90 per cent grade.

Naphthalene.—Sales of flakes are reported by makers at 6½c. per lb. Balls are moving quietly through first-hand channels at 8c. per lb., while odd lots have been sold a fraction under this figure. Crushed material is quoted at 6@6½c. per lb. The demand should be better at this season of the year.

The Chicago Market

CHICAGO, March 9, 1922.

No noteworthy changes occurred in the industrial chemical market during the past 2 weeks. Factors in this field report a fair volume of small orders and a good inquiry for prices. Competition is still very keen and a large request will usually bring out prices lower than the schedule. However, this tendency to cut is becoming less marked, especially on material of foreign origin where the replacement cost is considerably higher than the present spot market.

General Chemicals

The alkali market is unchanged as to price and the consuming demand remains light. Solid *caustic soda* is quoted at $3.75 per 100 lb. and the ground at $4.50, both prices being for ton lots with the material delivered to the consumer's plant. *Caustic potash* is exhibiting signs of strength and 6½c. per lb. was the rock bottom for ordinary lots to be delivered from spot stocks. *Soda ash* is moving in a routine way and is available at $2.30 per 100 lb. for material in cooperage.

Potash alum is rather scarce and whatever spot material is available is being quoted at 6c. per lb. for lumps and 7c. for powdered. *White arsenic* is still firm and is quoted somewhat higher at 8½@9c. per lb. *Blue vitriol* is in fair request with $5.90 per 100 lb. the inside for small or medium quantities. *Copperas* is also in good demand and is quoted at $1.75 per lb., single barrel lots. *Carbon bisulphide* is slightly easier and 6¾c. could probably be done on a fair-sized lot. *Carbon tetrachloride* is quiet and spot supplies could be had at 10½c. per lb., large drums extra. *Formaldehyde* is moving fairly well and at the present price of 10c. per lb. should be an attractive proposition. Competition has forced refiners of c.p. *glycerine* to lower their prices, the new schedule being 16c. per lb., bulk basis.

Bichromates are unchanged as to price although the movement is restricted to very small lots. *Potassium bichromate* is quoted at 11¾c. per lb., single cask lots, and sodium at 9@9½c., depending on the quantity and seller. *Red prussiate of potash* is still off of the spot market and as far as could be determined none is near by. *Yellow prussiate of potash* is very firm and is moving well at 27@28c. per lb. *Sodium fluoride* is attracting a little attention and is unchanged at 11c. per lb. for small or medium-sized lots.

Commercial *furfural*, reported for the first time in our letter of March 1, is still quoted at 50c. per lb. for quantities in excess of 100 lb. Rumors that imported furfural was available in the Eastern markets have not yet been confirmed.

The Iron and Steel Market

PITTSBURGH, March 10, 1922.

Production of steel ingots, which is an accurate and prompt reflection of the volume of steel demand when buying is for prompt shipment, has been practically stationary since the end of January, at a rate of about 29,000,000 tons per annum. During January and February there was a remarkably rapid increase. The American Iron and Steel Institute's reports of monthly production of thirty steel companies indicate that the annual rate at which the whole industry operated was as follows: In November, 23,300,000 tons; December, 19,750,000 tons; January, 22,750,000; February, 26,850,000 tons. These are approximations, with a probable error of less than half a million tons. The rate at the end of December was probably under 17,000,000 tons, while the rate in the past fortnight has been about 29,000,000 tons, an increase of 70 per cent or more.

The future would be discovered if the exact cause or causes of this increase in 2 months could be ascertained. "General conditions" or "underlying conditions" will not explain it, though it will explain a part. Liquidation of stocks will not explain it, for such liquidation was practically completed by Oct. 1, and a 23,000,000-ton rate of ingot production followed, for 2 months. The season of the year will not fully explain it, unless one is prepared to believe that when spring has actually arrived production will be much larger still. If all the buying has been of a strictly hand-to-mouth character, by far the heaviest demand is still to come.

Steel prices may furnish part of the explanation, particularly as we have an incident that may be illuminating. A few days ago the Jones & Laughlin Steel Co., one of the large independents, advanced its price on bars, shapes and plates to 1.50c. The market has been quotable at 1.35@1.50c. Previous to this withdrawal from the market, for that of course is what the action amounts to, the company is understood to have accumulated enough orders to carry it with its present operating rate for about 60 days. Perhaps the very low prices, well below what were expected to develop, influenced buyers to provide for the future to a certain extent.

The total demand has been practically constant in the past fortnight, as indicated by the steel ingot production rate. The only conspicuous absentee from the steel market has been the agricultural implement trade, and it has lately been buying a little steel to piece out its stocks preparatory to resumption of manufacturing in a modest way.

Sheet prices continue to be firmly held at 3c. for black and 4c. for galvanized, the rigid continuance of these prices for more than 3 months being the phenomenon of the steel market. Wire nails appear steady at the recent decline to $2.40, but there are rumors of less having been done. There is much talk of shading in standard steel pipe, but it is a fact that much business is done at substantially the regular prices. Tin plate is steady at $4.75 per base box, concessions on moderately large lots being usually 10 or 15 cents.

Pig Iron and Coke

On the whole the pig-iron markets are steady if not actually stiffening. Prices are reported a trifle better at Birmingham, Chicago and Philadelphia, while the local market is unchanged at $19@$19.50 for bessemer, $17.75@$18 for basic and $18.75@$19 for foundry, f.o.b. valley furnaces, freight to Pittsburgh being $1.96.

Lake Superior iron ore is likely to come down at least $1 a ton for the 1922 season. Shippers consider it practically certain that the rail rate from the Mesabi range to upper lake dock will be reduced from $1 to 75c. before the opening of navigation. The vessel rate will doubtless come down somewhat. It was 94c. last season, 14c. being paid by vessel to lower lake dock, leaving 80c. net. As prices are f.o.b. Lake Erie dock, these declines will affect the market price of ore, the ore shippers themselves standing some reduction at mine.

Connellsville coke has been holding its recent 50-cent advance, spot and prompt being $3.25@$3.50 for furnace and $4.25@$4.75 for foundry.

Coal-Tar Products

NOTE—The following prices are for original packages in large quantities:

Alpha-naphthol, crude	lb.	$1.00 — $1.05
Alpha-naphthol, refined	lb.	1.10 — 1.15
Alpha-naphthylamine	lb.	.30 — .31
Aniline oil, drums extra	lb.	.16½ — .17
Aniline salts	lb.	.24 — .26
Anthracene, 80% in drums (100 lb.)	lb.	.75 — 1.00
Benzaldehyde U.S.P.	lb.	1.25 — 1.30
Benzidine, base	lb.	.85 — .95
Benzidine sulphate	lb	.75 — .85
Benzoic acid, U.S.P.	lb.	.60 — .65
Benzoate of soda, U.S.P.	lb.	.55 — .57
Benzene, pure, water-white, in drums (100 gal.)	gal.	.29 — .35
Benzene, 90%, in drums (100 gal.)	gal.	.27 — .32
Benzyl chloride, 95-97%, refined	lb.	.25 — .27
Benzyl chloride, tech	lb.	.20 — .23
Beta-naphthol benzoate	lb.	3.75 — 4.00
Beta-naphthol, sublimed	lb.	.60 — .65
Beta-naphthol, tech	lb.	.27 — .30
Beta-naphthyla mine, sublimed	lb.	1.50 — 1.60
Cresol, U. S. P., in drums (100 lb.)	lb.	.12 — .15
Ortho-cresol, in drums (100 lb.)	lb.	.16 — .18
Cresylic acid, 97-99%, straw color, in drums	gal.	.50 — .52
Cresylic acid, 95-97%, dark, in drums	gal.	.45 — .47
Dichlorbenzene	lb.	.06 — .09
Diethylaniline	lb.	1.10 — 1.15
Dimethylaniline	lb.	.38 — .40
Dinitrobenzene	lb.	.22 — .25
Dinitroclorbenzene	lb.	.23 — .25
Dinitronaphthalene	lb.	.32 — .35
Dinitrophenol	lb.	.35 — .38
Dinitrotoluene	lb.	.22 — 24
Dip oil, 25%, car lots, in drums	gal.	.24 — .26
Diphenylamine	lb.	.59 — .70
H-acid	lb.	.85 — 1.00
Meta-phenylenediamine	lb.	.90 — 1.00
Monochlorbenzene	lb.	.14 — .15
Monoethylaniline	lb.	1.20 — 1.25
Naphthalene crushed, in bbls.	lb.	.06 — .06½
Naphthalene, flake	lb.	.06½ — .07
Naphthalene, balls	lb.	.08 — .08½
Naphthionic acid, crude	lb.	.65 — .70
Nitrobenzene	lb.	.10 — .12
Nitro-naphthalene	lb.	.30 — .35
Nitro-toluene	lb.	.15 — .17½
Ortho-amidophenol	lb.	2.75 — 2.80
Ortho-dichlor-benzene	lb.	.15 — .20
Ortho-nitro-phenol	lb.	.75 — 80
Ortho-nitro-toluene	lb.	.15 — .20
Ortho-toluidine	lb.	.20 — .25
Para-amidophenol, base	lb.	1.25 — 1.30
Para-amidophenol, HCl	lb.	1.30 — 1.35
Para-dichlorbenzene	lb.	.15 — .18
Paranitroaniline	lb.	.75 — .77
Para-nitrotoluene	lb.	.70 — .75

Industrial

Financial, Construction and Manufacturers' News

Construction and Operation

Alabama

ALTON—The Russell Clay Mfg. Co., Baltimore, Md., recently organized under Delaware laws, has acquired property at Alton, near Birmingham, for the operation of a new plant for the manufacture of vitrified paving brick and other burned clay products. It is planned to begin operations early in April, developing a capacity of about 50,000 bricks per day. The company is headed by L. S. Russell. Floyd B. Powell, Equitable Bldg., Baltimore, is manager.

CHOCTAW POINT—The Republic Creosoting Co. is planning for the rebuilding of the portion of its plant recently damaged by fire with loss estimated at about $12,000.

Arkansas

WALNUT RIDGE—The Industrial Bureau of the local Chamber of Commerce is perfecting plans for the establishment of a leather-tanning plant.

FORT SMITH—The Choctaw Brick & Gas Co., Kennedy Bldg., has acquired property at Mansfield, Ark., for the establishment of a plant for the manufacture of brick, tile and other burned clay products. Allen Kennedy is secretary.

California

RICHMOND—The Galena Signal Oil Co., Franklin, Pa., has acquired property at Richmond, comprising about 4 acres of land, near the works of the Standard Oil Co., for the erection of a new oil-refining plant, estimated to cost about $500,000. Construction will be commenced at an early date. Charles A. Miller, superintendent of the Franklin refinery, will be in charge of erection.

VERNON—The Pacific Petroleum Products Co. is planning for the rebuilding of the portion of its plant destroyed by fire, Feb. 16, with loss estimated at about $25,000.

LOS ANGELES—The Los Angeles Gas & Electric Co., 645 South Hill St., has had plans prepared for the erection of a 1-story compressor plant, 77 x 150 ft., on Center St., near Jackson St., to cost about $60,000, including machinery.

SAN FRANCISCO—The Los Angeles Soap Co., Los Angeles, has plans under way for the erection of a new 3-story and basement soap manufacturing plant, 100 x 160 ft., at 2nd and Brannan Sts., San Francisco, to cost about $150,000, including machinery. W. H. Crim, 425 Kearny St., San Francisco, is architect.

ALTURAS—The Stockton Match Co., Stockton, Cal., has acquired property at Alturas, as a site for the erection of a new plant. Plans will be prepared at an early date.

Delaware

WILMINGTON—The National Fibre & Insulation Co. has closed negotiations for the purchase of the plant and business of the American Vulcanized Fibre Co., Wilmington, Del., with branch factory at Newark, Del. The purchasing company will continue the operation of its present plant and headquarters at Yorklyn, Del., and will use the acquired plants as branches. General expansion in operation is planned. J. Warren Miller is president of the National company.

Florida

HIALEAH—The Hialeah Producing & Refining Co., 25 Second Ave., Miami, Fla., is planning for the erection of a new oil refinery at Hialeah, ner Miami, to cost about $200,000. It will be equipped for an initial output of approximately 1,000 bbl. per day. E. D. Noe is president.

Georgia

AUGUSTA—The Dunbar Brick Co. is planning for the rebuilding of the portion of its plant recently destroyed by fire with loss estimated at about $20,000. H. H. Stafford is head.

Idaho

KELLOGG—The Bunker Hill & Sullivan Mining Co. will build a new electrolytic zinc plant addition to its local plant, estimated to cost about $1,000,000, including machinery. It is expected to require about 24 months to complete the mill.

Illinois

MATTESON—The Mid-West Box Co., 111 West Washington St., Chicago, Ill., has preliminary plans under way for the erection of a new chemical plant at Matteson, to be 3-story, 60 x 140 ft., estimated to cost about $300,000, including equipment. K. I. Herman, company address, is in charge. Harvey C. Miller, 112 West Adams St., Chicago, is architect.

CHICAGO—Ludwig & Ludwig, 1611 North Lincoln St., are planning for the erection of a 2-story addition, 25 x 65 ft., to their leather tannery, estimated to cost about $25,000. Axel V. Teisen, 4804 North Kedzie Ave., is architect.

Indiana

COLUMBUS—With the dismissal of the receiver for the Indiana Oil Refining Co. and the return of the property to the company, plans are being arranged for the completion of its new oil-refining plant on property to the south of the city limits. The work is estimated to cost about $75,000. It is expected to have the refinery ready for service in about 60 days. Louis J. Scheidt is president.

FAIRMOUNT—The Fairmount Paper Products Co. will soon begin the erection of a new plant on Adams St., for the manufacture of paper specialties of various kinds. Harry Dwyer, Marion, Ind., is president and general manager.

VALPARAISO—The Chesterton China Co. is completing the erection of a new plant and plans to begin service in a portion of the works at an early date. Two of five kilns have been completed. It is expected to have the entire plant ready for capacity production early in the summer, giving employment to about 500 persons.

Iowa

FIGART—The Harbison-Walker Refractories Co., Farmers' Bank Bldg., Pittsburgh, Pa., has preliminary plans under consideration for the construction of a new plant at Figart, for the manufacture of firebrick and other refractories.

Kansas

COFFEYVILLE—The Sinclair Refining Co., 111 West Washington St., Chicago, Ill., will proceed at once with the erection of its new local oil refinery, upon which work was temporarily discontinued recently owing to labor difficulties. The company has arranged an appropriation of $3,000,000 for work on the refinery and affiliated structures during the present year.

Kentucky

LOUISVILLE—The Peaslee-Gaulbert Co., 15th and High Sts., manufacturer of paints, varnishes, etc., is planning for the erection of a plant addition to cost about $100,000, including equipment.

Louisiana

LAFAYETTE—The Benners Salt Co. has been reorganized under the name of the Lafayette Salt Co., with increase in capital to $500,000. The company plans for expansion at its plant at Anse La Butte, La., and will install equipment for increased production. J. J. Kean is manager.

Maine

BRIDGTON—The Simes Leather Co. has acquired the local tanning plant of A. G. Walton & Co., which has been closed for about 5 years. The new owner will remodel and improve the tannery, and plans to commence production at an early date. The former capacity will be increased.

Maryland

BALTIMORE—The Rennous-Kleinle Division of the Pittsburgh Plate Glass Co., 3221 Frederick Ave., is planning for the erection of a 4-story addition to its plant, 75 x 205 ft., to be equipped primarily for the manufacture of plate glass.

BALTIMORE—The Aromo Mfg. Co., 308 South Hanover St., recently organized with a capital of $100,000, is arranging for the establishment of a new plant for the manufacture of chemicals and affiliated products. Bids for equipment will be asked at an early date, including chemical machinery, mixing equipment, filtration apparatus, etc. Morris Bernstein is president, and Arthur W. Smith, vice-president and manager.

Michigan

PONTIAC—The Corodium Sand Brick Co., recently organized, has plans under way for the erection of a new plant on local property, and will break ground at an early date.

PORT HURON—The New Egyptian Portland Cement Co. has work under way on the remodeling and improving of the local shops of the Grand Trunk Railway Co., for a new cement mill, and will commence the installation of machinery at an early date. The property was acquired recently. Headquarters of the company are at 1213 Ford Bldg., Detroit. John Gillespie is president.

Missouri

MONETT—The Hammond Dehydration Co., J. H. Elpass, manager, will postpone for a number of months the erection of its proposed new plant, estimated to cost about $50,000. Heckenlively & Mark, 642 Landers Bldg., Springfield, Mo., are architects.

New Jersey

BUTLER—The Bloomingdale Rubber Co. will make a number of improvements in its local plant for the manufacture of rubber specialties, and will remove the reclaimed rubber department to its works at Chester, N. J. The local plant will be enlarged and employment given to about 50 additional persons.

SAYREVILLE—Fire Feb. 25 destroyed a portion of the plant of the Sayre & Fisher Co., manufacturer of brick and other burned clay products, with loss estimated at about $40,000.

TRENTON—The Henry R. Fell Co., East Carroll St., manufacturer of concrete roofing tile, will install additional equipment for increased production. J. Henry Fell is head.

New York

BROOKLYN—Fire Feb. 23 destroyed a portion of the plant of the Williamsburg Chemical Co., 230-2 Morgan Ave. An official estimate of loss has not been made.

BROOKLYN—J. M. Huber, 602 62nd St., manufacturer of colors, etc., has awarded a contract to Smith & Leo, 103 Park Ave., New York, for the erection of a 2-story addition, 36 x 52 ft., at the corner of 62nd St. and 6th Ave.

Pennsylvania

ELIZABETHTOWN—The Farmers' Fertilizer Works, William Schneitman, head, will soon commence the erection of a new plant building, 1-story, 90 x 140 ft.

PHILADELPHIA—The Wittman Moriarty Co., 4th and Vine Sts., manufacturer of leather products, has acquired property at Westmoreland and B Sts., as a site for the construction of a new plant, 75 x 105 ft., estimated cost $75,000. The tract totals 240 x 350 ft., for future expansion, and was secured for a consideration of about $30,000.

Tennessee

MEMPHIS—The National Waterproofing Co. is planning for the rebuilding of the portion of its plant, recently destroyed by fire with loss estimated at about $175,000.

Texas

EASTLAND—Butler Bros. have acquired property on the J. L. Johnson tract, near the city limits, as a site for the immediate erection of a new gasoline absorption plant, with capacity of about 12,000 gal. per day. It will cost about $300,000. This will be the first of a series of plants to be established by the company, with complete cost estimated at $1,500,000.

Washington

SPOKANE—The Standard Stoneware Co., Spokane, Wash., is planning for the erection of a new pottery for the manufacture of earthenware and stoneware products, to cost about $25,000. Charles Stormes is head.

Capital Increases, etc.

THE FILER FIBRE CO., Filer City, Mich., manufacturer of fiber products, has filed notice of increase in capital from $450,000 to $1,000,000.

THE SCOTT TILE CO., Paris, Tex., manufacturer of ceramic tile, has filed notice of increase in capital from $15,000 to $35,000.

THE ATOMIZED PRODUCTS CO., Evansville, Ind., has filed notice of increase in capital from $200,000 to $500,000.

THE SLAYMAKER ELECTRIC WELDING CO., Detroit, Mich., has filed notice of increase in capital from $28,000 to $50,000.

THE OXFORD PAPER CO., Rumford, Me., has arranged for a bond issue of $5,000,000, the proceeds to be used for general operations. The company has completed negotiations for the purchase of the Rumford Falls Power Co. James A. Harris is general manager.

THE INDIAHOMA REFINING CO., operating oil refineries at East St. Louis, Ill., and Okmulgee, Okla., has arranged for a note issue of $900,000, for general operations, financing, etc.

Robert C. Rand has been appointed receiver for the ARISTA CHEMICAL CO., 305 Broadway, New York, N. Y.

THE HARBISON-WALKER REFRACTORIES CO., Pittsburgh, Pa., manufacturer of firebrick and other refractory products, has arranged for a decrease in capital from $36,600,000 to $30,000,000. A special meeting of stockholders will be held on March 16.

Plans are being perfected for a merger of the BUTTE-BULLWHACKER CO., and the BUTTE-DULUTH COPPER CO., both of Butte, Mont., operating local copper-leaching plants.

THE MCGEARY FIREBRICK CO., Pittsburgh, Pa., has filed notice of dissolution under state laws.

THE OWOSSO BRONZE BEARING CO., Owosso, Mich., has filed notice of dissolution under state laws.

THE EXCELL BRASS FOUNDRY, 819 Frelinghuysen Ave., Newark, N. J., has filed notice of organization to manufacture brass, bronze and other metal castings. Thomas Proctor heads the company.

THE WALDO OIL CO., New York, N. Y., has been incorporated under Delaware laws, with a capital of $100,000, to manufacture petroleum products. The company is represented by the United States Corporation Co., 65 Cedar St., New York.

New Companies

THE MICHIGAN PORCELAIN TILE WORKS, INC., Ionia, Mich., has been incorporated with a capital of $100,000, to manufacture floor and wall tile and other ceramic products. The incorporators are Royal A. Hawley, Harry E. Kidder and T. B. Duston, all of Ionia. The company will build a local plant.

THE SANITARY FIBER CO., 342 South Hoyne Ave., Chicago, Ill., has been incorporated with a capital of $50,000, to manufacture fiber products. The incorporators are William W. Newell, R. F. Locke and Frank L. Childs.

H. F. SOMMER & CO., INC., Newark, N. J., has been incorporated with a capital of $100,000, to manufacture leather products. The incorporators are Harry F., J. F. and William M. Sommer. The company is represented by Bilder & Bilder, 790 Broad St., Newark.

THE ALLIED PAPER MILLS, INC., New York, N. Y., has been incorporated with a capital of 1,000 shares of stock, no par value, to manufacture paper products. The incorporators are S. B. Monroe, A. C. Gilman and F. A. Wagner. The company is represented by Davis, Wagner, Hester & Holton, Mutual Life Bldg., New York.

THE WON-DA PRODUCTS CO., INC., Hartford, Conn., has been incorporated with a capital of $100,000, to manufacture soaps, oils, compounds, etc. The incorporators are H. L. Rose, A. Goldberg and Richard Ryder, 46 Capen St., Hartford.

THE PURITAN REFINING CO., New York, N. Y., has been incorporated under Delaware laws with capital of $100,000, to manufacture refined oil products. The company is represented by the United States Corporation Co., 65 Cedar St., New York.

THE OIL CITY LUBRICANTS CORP., 1401 Madison Ave., Baltimore, Md., has been incorporated with a capital of $50,000, to manufacture oils, greases, etc. The incorporators are William S., F. A. and W. W. Paca.

THE UNDERCOAT PAINT CO., New York, N. Y., has been incorporated with a capital of $35,000, to manufacture paints, varnishes, etc. The incorporators are N. C. Latter, L. F. Kuntz and T. C. Tocknell. The company is represented by H. W. Kiralfy, 565 Fifth Ave., New York.

THE METUCHEN DYESTUFF CORP., Metuchen, N. J., has been incorporated with a capital of $100,000, to manufacture colors, dyes, chemicals, etc. The incorporators are Saul Ceasar, Albert G. Rich and Alexander C. Connor, Durham Ave., Metuchen.

THE CONTINENTAL LEATHER CO., Wilmington, Del., has been incorporated under Delaware laws with capital of $7,500,000, to manufacture leather products. The company is represented by the Corporation Trust Co. of America, du Pont Bldg., Wilmington.

THE NONTOXO CHEMICAL CO., South Bend, Ind., has been incorporated with a capital of $10,000, to manufacture chemicals and chemical byproducts. The incorporators are John A. King, M. G. Mock and Louis J. Smith, all of South Bend.

THE PLEASANT LAKE MARL CO., Three Rivers, Mich., has been incorporated with a capital of $5,000, to manufacture lime and fertilizer products. The incorporators are Oliver T. Avery, F. A. Rohrer and M. W. Lott, all of Three Rivers.

THE ESSEX PAPER PRODUCTS CO., Lawrence, Mass., has been incorporated with a capital of $25,000, to manufacture paper goods. Albert J. Quimby is president, and Daniel J. Crowley, Jr., Lawrence, treasurer.

THE GRAHAM REFINING CO., Graham, Tex., has been incorporated with a capital of $30,000, to manufacture refined oil products. The incorporators are M. K. Graham, J. C. Kilgore and Thomas Morrises, all of Graham.

THE CONSUMERS' COLOR & CHEMICAL CO., 1823 West Lake St., Chicago, Ill., has been incorporated with a capital of $10,000, to manufacture chemicals, chemical byproducts, etc. The incorporators are Adam Heckmann, Samuel J. Hefti and Gustav Ruchheit.

THE BALTIMORE CEMENT PRODUCTS CO., INC., 525 Overland Ave., Baltimore, Md., has been incorporated with a capital of $25,000, to manufacture brick, pipe, blocks and kindred products. The incorporators are Herbert L. and D. Lee Bowen, and George S. Hiller.

THE MATAWAN COLOR CO., Matawan Park, Matawan, N. J., has been incorporated with a capital of 500 shares of stock, no par value, to manufacture chemicals, colors, etc. The company is represented by Arthur W. Britton, 65 Cedar St., New York, N. Y.

THE BELLROSE STANDARD SILICA CO., Ottawa, Ill., has been incorporated with a capital of 3,500 shares of stock, no par value, to manufacture silica products. The incorporators are Robert O. Farrell, Holland M. Cassidy and Jesse Halsted, Ottawa. The company is represented by Chapman, Cutler & Parker, 111 West Monroe St., Chicago, Ill.

THE GOLD SEAL OIL CO., Reading, Pa., has been incorporated with a capital of $110,000, under Delaware laws, to manufacture petroleum products. The incorporators are Charles E. Keyee, Reading; Samuel T. Newhardt and Paul F. Erdman, Allentown, Pa. The company is represented by the Corporation Service Co., Wilmington, Del.

THE GOHEEN CORP. OF NEW JERSEY, Newark, N. J., has been incorporated with a capital of $20,000, to manufacture paints, varnishes, etc. The incorporators are S. Michael Cohen, Manuel M. Voitt and Nathaniel X. LePeau, 202 Emmet St., Newark.

THE LOUIS MESKAN BRASS FOUNDRY, INC., 422 South Robey St., Chicago, Ill., has been incorporated with a capital of $12,000, to manufacture brass, bronze and other metal castings. The incorporators are Louis Meskan and Edward Schauble.

THE BLUE DIAMOND MORTAR CO., 1007 Candler Bldg., Atlanta, Ga., has been incorporated with a capital of $150,000, to manufacture lime and affiliated products. A. P. McCallie is president and general manager; and B. Graham West, secretary and treasurer.

THE KEYSTONE REFINING CO., Brooklyn, N. Y., has been incorporated with a capital of $10,000, to manufacture oil products. The incorporators are C. D. and D. Flanel, and S. Glaser. The company is represented by E. M. Ostrow, 63 Park Row, New York.

THE RODGERS PRINTING INK CO., New York, N. Y., has been incorporated with a capital of $10,000, to manufacture inks and affiliated products. The incorporators are J. E. and J. M. Rodgers, and T. F. Torley. The company is represented by J. A. Turley, 233 Broadway, New York.

CHRISTIAN FLEISSNER, INC., Newark, N. J., has been incorporated with a capital of $150,000, to manufacture leather products. The incorporators are A. Fleissner, H. Croan and Christian Fleissner, 125 New Jersey Railroad Ave., Newark.

THE OSSIE OIL CO., Tulsa, Okla., has been incorporated with a capital of $100,000, to manufacture petroleum products. The incorporators are T. B. Reese, Eugene DeBorgory and W. Shilig, all of Tulsa.

THE UNITED STATES REFRACTORIES CO., INC., Boston, Mass., has been incorporated with a capital of $200,000, to manufacture firebrick and other refractory products. Arthur W. Leavitt is president; and Dagmar Anderson, Dorchester, Mass., treasurer.

THE LIBERTY COLOR & CHEMICAL CO., Philadelphia, Pa., has been incorporated with a capital of $25,000, to manufacture chemicals, chemical byproducts, etc. Thomas D. O'Brien, 3911 North Park Ave., Philadelphia, is treasurer.

THE COMMERCIAL CHEMICAL CO. OF TENNESSEE, Nashville, Tenn., has been incorporated with a capital of $2,500,000, under Delaware laws, to manufacture chemicals and chemical byproducts. The company is represented by the Corporation Trust Co. of America, du Pont Bldg., Wilmington, Del.

THE NEW SOUTHERN OIL CO., Dallas, Tex., has been incorporated with a capital of $75,000, to manufacture petroleum products. The incorporators are C. U. Connellee and O. B. Colquitt, both of Dallas.

THE ORA-LEE CO., Wilkes-Barre, Pa., has been incorporated with a capital of $30,000, to manufacture extracts, compounds, etc. John M. Walsh, Wilkes-Barre, is treasurer.

WISS SONS, INC., Newark, N. J., has been incorporated with a capital of $300,000, to manufacture glass products. The incorporators are Frederick, C. J. and Jerome B. Wiss, 665 Broad St., Newark.

THE MAMMOTH OIL CO., Wilmington, Del., has been incorporated with a capital of $100,000,000, under Delaware laws, to manufacture petroleum products. The company is represented by the Corporation Trust Co. of America, du Pont Bldg., Wilmington.

Coming Meetings and Events

AMERICAN CHEMICAL SOCIETY will hold its spring meeting at Birmingham, Ala., April 4 to 7, 1922.

AMERICAN ELECTROCHEMICAL SOCIETY will hold its spring meeting in Baltimore, April 27, 28 and 29, 1922. Headquarters will be at the Emerson Hotel.

AMERICAN FOUNDRYMEN'S ASSOCIATION will hold its next convention and exhibit at Rochester, N. Y., during the week of June 5, 1922. Meetings will be held in the spring instead of in the fall as heretofore.

AMERICAN INSTITUTE OF CHEMICAL ENGINEERS will hold its summer meeting at Niagara Falls, June 19 to 22. Headquarters will be at the Clifton Hotel.

AMERICAN SOCIETY FOR STEEL TREATING will hold a sectional meeting at the Bureau of Mines auditorium, Pittsburgh, Pa., on May 25 and 26. The International Steel Exposition and Convention of the society will be held in the General Motors Bldg., Detroit, Mich., Oct. 2 to 7.

AMERICAN SOCIETY FOR TESTING MATERIALS will hold its twenty-fifth annual meeting June 26 to July 1, at Atlantic City, N. J. Headquarters will be at the Chalfonte-Haddon Hall Hotel.

INTERNATIONAL UNION OF PURE AND APPLIED CHEMISTRY will hold a meeting at Lyons, France, June 27 to 30.

IRON AND STEEL INSTITUTE (British) will hold its annual meeting on May 4 and 5 at the House of the Institution of Civil Engineers, Great George St., S. W., 1, London.

NEW JERSEY CHEMICAL SOCIETY holds a meeting at Stetters Restaurant, 842 Broad St., Newark, N. J., the second Monday of every month.

STAMFORD CHEMICAL SOCIETY, Stamford, Conn., holds a meeting in the lecture room of the local high school on the fourth Monday of each month, except June, July, August and September.

The following meetings are scheduled to be held in Rumford Hall, the Chemists Club, New York: March 24—Society of Chemical Industry, regular meeting; April 21—Society of Chemical Industry (in charge), American Electrochemical Society, Société de Chimie Industrielle, American Chemical Society, joint meeting; May 5—American Chemical Society, regular meeting; May 12—Société de Chimie Industrielle (in charge), American Chemical Society, Society of Chemical Industry, American Electrochemical Society, joint meeting; May 19—Society of Chemical Industry, regular meeting; June 9—American Chemical Society, regular meeting.

The Explosibility Of Ammonium Nitrate

WHEN the nitrogen fixation works of the Badische Company at Oppau were destroyed by a tremendous explosion last September, the interest of American scientists and manufacturers of explosives was immediately aroused on account of the apparently mysterious cause of the disaster. It was known in a general way what was going on at Oppau—the fixation of atmospheric nitrogen by the Haber process and the manufacture of nitrogen fertilizers, among which was a combination of ammonium nitrate and ammonium sulphate—and yet no valid reason could be assigned for the explosion. Although it was ascertained subsequently that the explosive decomposition of 4,500 tons of sulphonitrate of ammonia was responsible for the disaster, the cause is still unexplained. Investigations begun abroad and in this country are still in process from which it is hoped information will be derived not only to serve as an explanation of what happened at Oppau but to guide us in our own development and use of synthetic nitrogen fertilizers. The investigations are of particular importance in view of the rapidly expanding use of ammonium nitrate.

In our attempts to throw as much light as possible on the explosion we gathered material from various sources, and in an editorial comment on November 2, 1921, we made the following statement:

> Furthermore we are confronted with the fact that ammonium nitrate itself is something of a mystery. Those who know anything about powder plants cannot help recalling instances when it acted as it shouldn't. We are told that once upon a time, of twenty vessels working up ammonium nitrate, No. 6 and No. 18 suddenly exploded, demolishing several others. At the same instant some barrels of nitrate in a storage shed went off and only scattered holes in the ground were left to mark the places where they stood. Surrounding barrels were broken and charred, but did not explode.

The purport of our comment was to convey an idea that we found prevalent—namely, that there was a general lack of precise knowledge of the properties of ammonium nitrate and that consequently it was "something of a mystery" with regard to its explosibility. It appears, however, that our opinion was interpreted as meaning that one could not tell under what conditions ammonium nitrate might explode and that, therefore, there were some inherent and unknown dangers in its manufacture, transportation, handling and storage. This, of course, was a misinterpretation of our thought, because as far as we were then or are now aware, ammonium nitrate is explosive only under exceptional conditions of high pressure and powerful detonation. Our comment was, however, open to this criticism: That due to lack of complete information we made it appear that the two explosions mentioned were almost simultaneous, one dependent on the other, whereas they were widely separated, not only as to time but also as to locality.

What are the facts as to the explosibility of ammonium nitrate? Considering the apparent lack of precise knowledge of its properties and behavior, it seemed advisable, in the interest of scientific accuracy as well as industrial progress, to obtain from an authoritative source an article embodying our present knowledge of the material and of explosions in which it has played a part. Such an article is published in this issue from the pen of Dr. CHARLES E. MUNROE, Chairman of the Committee on Explosives Investigations, National Research Council. The merit of Dr. MUNROE'S article will be apparent to all who read it, but we may indicate some of its points of excellence. In the first place, it is a complete compilation of the known properties and behavior of ammonium nitrate; second, it embodies the only authoritative statements that have ever been published regarding four important disasters in which ammonium nitrate played a part; and third, it gives the results of tests on the explosibility of ammonium nitrate made in this country after the Oppau disaster. It will thus be seen that the article is an important contribution to our knowledge of the subject, and we believe there can be no dissension from the conclusions of the author, that while ammonium nitrate offers a fire hazard, it cannot be regarded as an explosive *per se* under ordinary conditions of transportation and storage.

Effectively Crippling Chemical Warfare Service

THE appropriation of half a million dollars for the next fiscal year's work of the Chemical Warfare Service was well characterized by one prominent government official as "absurdly small." This sum is wholly inadequate to the responsibility which is placed upon this branch of the Army, and it is to be hoped that the House of Representatives or the Senate will find occasion to increase this sum, which has just been recommended by the House Committee on Appropriations.

The report of this committee includes the following comment:

> The budget estimate for Chemical Warfare Service was $1,500,000, which was later reduced to $500,000 in view of present conditions. The latter amount is recommended by the committee to provide for a minimum amount of development work and training along lines compatible with present conditions, and maintaining Edgewood Arsenal in stand-by condition.

Behind this statement there is a bit of interesting history. The budget estimate was for continuance of C.W.S. on the same basis as recommended a year ago, but during the hearings on the bill certain officials in the War Department and the Army appeared before the Congressional sub-committee which was holding hearings and changed the basis of the recommendation. It is understood that they not only reduced to one-third the appropriation originally requested but also urged that C.W.S. be abolished and that the smaller sum recom-

mended be granted to the Ordnance Department, which, in their judgment, should do the work now under C.W.S.

In the course of writing the treaties at the Conference for the Limitation of Armaments, it became evident that the Chemical Warfare Service had influential enemies in high position; recent developments emphasize this fact. These officials apparently have succeeded now in making a move for crippling the Service.

The chemical industries of the country have come to look upon the Chemical Warfare Service as one of the links in our chain of industrial chemical activities. Our industries cannot view without apprehension any curtailment of the fundamental research and development activities of C.W.S. Chemists know too well from experience that the development of chemical agencies of attack or defense is not the work of days or weeks, but rather of months and years. They know how foolhardy it is for our nation to remain unprepared in matters such as this. They know that only chemists working under sympathetic supervision of other chemists can maintain the intimate acquaintance with chemical industry upon which chemical warfare of the future will so much depend if the occasion ever should arise for this type of military activity.

The officers of the Chemical Warfare Service are keenly alive to the seriousness of the situation. They are doing everything in their power to present fully to our legislators the pertinent facts. But they need and well deserve the co-operation of chemists and chemical industry generally. These latter must make it known that they do not regard as a safe procedure the curtailment of chemical warfare studies in any such ruthless manner as this. Moreover, they should make it evident to Congress that such curtailment is false economy, for through no other arm of the service can the defense of the country be so cheaply and effectively planned. Studies for defense are not prohibited by the letter or spirit of the pending treaty.

"Not Much Hope For Better Cement"

THIS is the heading under which one of the leading engineering and construction journals of the country recently presented a portion of its editorial review on concrete and cement. It is unfortunate that engineers who use most of the cement in the United States should be given this impression. Certainly the chemical industries in general, and the cement industry in particular, are not prepared to admit that there is no further opportunity for improvement of portland cement.

The review in question acknowledged that practically all commercial supplies of cement pass the present standard specifications and that proper use would almost invariably insure a certain strength of construction. However satisfactory this condition may be in general, it is not a welcome thing to have the added thought expressed "that the cement makers themselves are satisfied with the present situation, and that they are more anxious to preserve the present standard specification than to get a better product." It may be that a few in the business would be willing to take such a stand privately, but it is certain that there are in the portland cement industry of today those who are not content to permit this product, good as it is, to remain indefinitely of only the present standard of value.

Standard specifications of the sort which are now widely used for cement are certainly much more satisfactory than the many diverse specifications which were common 10 or 20 years ago. But present standards must not become a deadening influence on the industry. Progress must be maintained. And progress means continued increase in the rigidity of the specifications.

Any industry which would accept without challenge such a charge as has been made against cement would soon find itself supplanted by newcomers in the business or by other branches of industry which would furnish substitute products. Research is essential to progress in any business, and research must and will continue regarding materials, methods and marketing of portland cement. It is to be hoped that this criticism, which we believe is unjust, may prove an added stimulus to the industry for greater advancement.

A Suggestion for Fixing Wage Scales

ON MARCH 4 the Chemists' Club of New York had one of its several Saturday luncheons with speakers who are guaranteed not to be chemists. On this occasion IVY LEE, adviser to the Association of Railway Presidents in matters of publicity, spoke on "The Railroad Situation," and HUGH FRAYNE, organizer for the American Federation of Labor, on "What Labor Wants."

Both talked about wages, and they were in entire accord about the Railway Labor Board. Both agreed that the very presence of such a tribunal invited dispute, and that before a tribunal each side is likely to present maximum claims as minima—in other words, to bid high for itself. They were in agreement also that the best settlers of problems at issue are the interested parties themselves.

We have not space to review the many other features of the railroad situation brought out by Mr. LEE, or to record their sometimes sympathetic and sometimes opposing views in regard to the problems of labor. But to an attentive listener it seemed that both were talking around the fringes of applied psychology.

There is the unsolved problem of the feeble-minded in the ranks of labor. That was not discussed. It stands to reason, however, that they naturally gravitate to those occupations that do not call for mentality in work and that, like children, these defectives keep organized labor "in wrong" by their frequent breaches of agreement and their resorts to violence.

We believe, however, that the opportunity offers itself for a step in advance in the interest of both employers and organized labor, although it would have to be tried out in some establishment in which the employer and his organized workmen are on terms of cordial amity. There must be confidence on all sides for the experiment to be tried. Then the employer can say to the representatives of his men:

"We have a payroll of n dollars a week, and what I propose will not change that. And I do not propose any changes in the hours of labor. But in fixing rates of pay and in all our agreements, we have both been guessing. We have guessed and compromised to reach our present scale. We do not really know the comparative value of the service done in the various jobs in these works. Applied psychology can integrate these various parts of the work and fix comparative values. I propose to get from President ANGELL of Yale or President HAMERSCHLAG of Carnegie Tech of Pittsburgh, or from somebody else, a couple of good, experienced psychologists to come here and make a study of a comparative wage scale for our work. They won't

know anything until they have been here for several months. After they have made their study, however, they are to make their report and then let us take it up together. We shall not propose to cut wages for any job below an agreed minimum, but I want to know which positions carry the responsibility and to put a premium on these. I want also to know which positions do not call for thinking, and to keep them for our men who can't remember or can't see ahead. I shall not attempt to put through any new schedule until we have agreed on it, and I want you men to make this study with me."

By this means he would provide better pay for his more competent and ambitious men. He would take care of the incompetents who now drag the others down. He would establish an *esprit de corps* that would otherwise be unavailable. And he would do more for organized labor if he were to work this problem out with his men than forty new laws and a hundred strikes.

A Short Road To Fame

THERE was a time when it seemed to us that the peak of fame was attained when a locomotive with red wheels and brass trimmings was named for a man. With increasing stature our taste in fame changed, and we thought if our name were used for a good, free-smoking 5 cent cigar, for the purpose of drawing custom to it, that would represent popularity if not fame. Now with the mask of age grinning in the western offing our ambitions have become less definite.

But here is a new opportunity to make a name known. The chemical laboratories of the leading Polish universities and polytechnic institutes are without equipment. Every bit of platinum and all apparatus and reagents have been taken away by the armies that passed through. The students are there, and so are the professors, but they can't demonstrate, and they can't buy anything with Polish marks, and Polish marks are all they have. These are the universities of Lwow (Lemberg), Warsaw, Cracow, Posen and Wilno, and the Polytechnic Institutes at Lwow and Warsaw. At the current rate of exchange all their chemical laboratories could be generally equipped for about ten thousand dollars. The country is very democratic; they haven't any Order of the Green Eagle of the Sixth Class or Knighthood of the Royal Shoe Lace or other decorations to bestow. But they would put up a tablet in each laboratory, worded in Polish somewhat to this effect: "This laboratory was equipped after the devastation of war through the generosity of JOHN JONES, president of the Jones Company, Jonesville, Ohio, U.S.A." Then generations of educated Poles would honor and respect his name in enduring gratitude. It would be known throughout Poland. There would be Jones legends and Jones myths, all told with a whizzing and skyrocketing accompaniment of consonants in the Polish language. They would burn candles in memory of him when he died, and call their babies after him. He would stride down the aisle of Fame as the Benefactor of Science in Poland.

Any sum may be sent to HUGH GIBSON, U. S. Minister to Poland in Warsaw, for the purpose named, to be distributed through the Mianowski Foundation, of which the director is Dr. S. MICHALSKI, Vice-Minister of Education, and the Council is made up of representatives of the different universities.

How Did the 1919-20 Boom Happen?

WHEN business began tapering off in the latter part of 1920 the talk immediately arose that there was "a strike of buyers" and when business began to appear really stagnant a common remark was that resumption of activity merely awaited the quoting of lower prices—that men knew just what they were waiting for. Apparently we had the situation "doped out" pretty well.

More recently, however, there is a new view. There is not going to be a return to 1919-20 conditions, minus fancy prices. It is proved to be impossible to do that. We cannot have a much higher scale of living than we had before the war, and we may not be able to have even as good a scale, until we have made up for the waste of war. We shall have to work harder and more efficiently in order to get along at all.

The new teaching is very logical and appealing. It appears to hang together very nicely and to be in harmony with all the known facts, with one exception. The exception is that if these things are impossible, a better scale of living, more income with less work and all that sort of thing, how is it that it did happen in 1919 and 1920?

A partial but more than a 50 per cent answer is that it didn't. We did not have nearly as great industrial activity in 1919 and 1920 as we thought we had. We took our cue altogether too much from prices, judging that because a material was high priced it was in very heavy demand and that demand was outrunning supply. In many cases the supply was not large, and part of it was held back by speculators. Then, furthermore, we judged the physical volume of trade too much by the money standard. Reduced to physical units the quantity of business was not so large. Applying to the record of money turnover, as shown by debits to individual accounts at banks, a correction on account of prices and inflated values, it appears as if the physical volume of business was less in 1920 than in 1919 and that in 1921 it was larger than in 1920.

The explanation of the 1919-20 industrial activity—that it didn't occur—is incomplete. All the rest of the answer may not be available at the moment, but some further explanation of the phenomenon can be found. We had what appeared to be an active and profitable export trade, but the records show that a large part of the exported merchandise has not been paid for. According to the Federal Reserve Board's investigation, about three billion dollars of unfunded balance due to the United States accumulated during 1919 and 1920. We did not know at the time that we were not going to be paid with reasonable promptness, and in respect of this amount we were less prosperous than our imagination led us to believe.

Then we had some fictitious prosperity through the spending of what were considered profits made during the war, both before and after the United States entered. In numerous cases high prices were paid for commodities, the extra price being paid to reimburse the producer for the cost of additional plant facilities which would be more or less valueless after the war, but the recipients called the money real profits and did not apply it to writing down the property account.

In time it will no doubt be possible to explain away the apparent boom in 1919 and 1920, but we know enough already to be willing to admit that positively we cannot, in consequence of a great war, consume more in proportion to what we produce than we used to do.

Readers' Views and Comments

When Does an Employment Contract Terminate?

To the Editor of Chemical & Metallurgical Engineering

SIR:—Having read the editorial in your issue of Feb. 22, page 338, and the comments of Wellington Gustin, page 341, I would like to point out to you that there is considerably more in this question than is indicated either in the editorial or in the communication referred to.

In the first place, if you will refer to "American and English Decisions in Equity," vol. 9, you will find that the appellate courts have decided such subjects as "Property Rights in Trade Secrets," "Who May Be Enjoined From Using or Disclosing Trade Secrets," "Contracts Not to Use or Communicate Trade Secrets," "Implied Contract Not to Divulge Trade Secrets," "Use of Knowledge Acquired During Employment" and the "Status of an Employee Who Discovers Secrets," together with many other decisions which more or less form complete information on the subject referred to.

I have in mind two cases which I arbitrated which come under this particular heading.

A certain firm engaged a chemist to make for it a number of improvements in one of its processes. This the chemist did and during the course of his work he made some important discoveries, which he patented. Before going to law in the first case, both the chemist and the employer decided to permit me to arbitrate the case, and I decided in favor of the chemist on the ground that he rendered useful service for the wages he received and that he was entitled to extra recompense for the intellectual property which he possessed, and the case was very satisfactorily settled, the chemist turning over the patents for what I considered a reasonable sum.

In another instance an improvement was made in a piece of apparatus which rightfully belonged to a chemist who had worked it out during his employment, and I again decided in favor of the chemist on the ground that he had given full value for the wages he obtained in the first place, and in the second place there was no contract between employer and employee which implied that the chemist was to turn over without consideration any invention that he should make. On the other hand, there is a well-known implication of law which works the other way, that no chemist after he leaves the corporation can make use of a process which he has learned during the time that he is employed. The rule in equity which is followed in this case is that when you engage a butler you do not tell him that he must not steal your silver, for such a condition is implied, so that anyone leaving a corporation's employ and taking with him intellectual property which he has acquired without any efforts of his own is clearly not entitled to use such information for his own benefit.

The whole question may be summed up into this, that chemists and other intelligent employees are engaged verbally or by written contract, and the question of intellectual property is seldom entered into. If a man obtains a position and gets a fair salary and makes a contract in writing that he will turn over all his discoveries in consideration for the salary he obtains, the decision in a case of that kind must be very obvious, but where nothing is stated, and where both parties are fair, it is very simple to arrive at a just conclusion, as in the two cases which came before my notice.

I have always contended that every professional man ought to listen to a six months' course of lectures on contracts during or directly after his college course.

New York City. MAXIMILIAN TOCH.

To the Editor of Chemical & Metallurgical Engineering

SIR:—I wish to write you regarding your editorial on "When Does an Employment Contract Terminate?" in the issue of Feb. 22 and the interesting comment on it made by your Chicago correspondent in the same issue.

This writing of proper contracts is difficult. If in error, they have been generally unfair to the technical employee rather than to the corporation. About the only constructive criticism I have heard, other than that given by your Chicago correspondent, has been that the American Chemical Society or perhaps the more progressive and smaller organization, the American Institute of Chemical Engineers, should employ an attorney to get out forms of standardized contracts and also should arrange for this attorney to advise any chemist or chemical engineer as to proper types of contracts or as to the true meaning of contracts which are offered him by a corporation. It seems to me that it ought to be possible without great difficulty to get typical standardized contract forms which would be fair to both the technical man and the employer. RALPH H. MCKEE.

Department of Chemical Engineering,
Columbia University,
New York City.

To the Editor of Chemical & Metallurgical Engineering

SIR:—I read with considerable interest your editorial and comment regarding the relation of a chemist to his former employer.

When a man is doing research work, this research work is rather specific. He is either working on a particular compound or group of compounds, or on a particular reaction. The chemist brings to this work certain training and experience. The employer brings, we will say, certain private plant information and commercial knowledge. They work together on some agreed-on basis, and the results of the work, whatever they are, belong to the employer. Suppose the chemist quits or loses his job. What is his status? He has the same training and equipment as he had before he started on this particular piece of work, and he has in addition the advantage of experience in doing the work. The employer has taken nothing from him but the results of a particular piece of work, and presumably it was agreed in advance, for a definite remuneration, that these results should belong to the employer. The chemist is now free to find another job, and as far as I can see the whole field of chemistry is open to him without question, excepting the specific reaction or the specific compound or group of compounds on which he worked for this employer.

In long experience as a consultant with many employers I have never had a difference of opinion with any of them as to what lines it would be proper for me

to follow and what lines I should not follow in view of the work I had done for them and the private information they had necessarily given me. In dealing with chemists who work for me or under me, I have never had a difference of opinion either. In this latter case I ordinarily ask the men to refrain for 3 years from working on the particular problem on which they were doing research work for me. This is no limit of any consequence to the usefulness of the chemist or the broadness of his field of work, and sufficiently protects the employer. If there is a clear understanding at the outset of the work as to what the arrangement is under which the work is being done, and any tendency to be fair on both sides, no real question of conduct will arise at all. JOHN E. TEEPLE.

New York City.

To the Editor of Chemical & Metallurgical Engineering

SIR:—I have read both articles in CHEMICAL & METALLURGICAL ENGINEERING on "When Does an Employment Contract Terminate?" and I feel that there is a certain injustice in the rigid conditions that are often incorporated in the employment contracts of chemists and chemical engineers, but there are two sides to this question.

With a chemist who has actually brought something to his employer which is his own work and his own idea, the chances that his services will be dispensed with are very slight. Even under present heart-breaking conditions when it is imperative to reduce expenses to a minimum to safeguard the future of many establishments, he is likely to be retained. Such men in addition to a salary are as a rule given a share of the profits or savings of their invention and these payments continue for stipulated periods if for one reason or another they sever their connections with the firm.

If, on the other hand, a young man is taken into a laboratory or works where secret processes are in operation, with the development of which he has had nothing to do but with which he is made familiar in order to supervise their working, I think it is perfectly fair that he should be restrained from using such knowledge for his own benefit or that of others. Often such processes are based on the preliminary work on other products produced by his employer and are the result of years of untiring labor and the expenditure of vast sums.

In such cases a contract prohibiting him from engaging in work of a similar nature for a period of years is perfectly fair and equitable. F. G. ZINNSER.

Hastings-on-Hudson, N. Y.

The Needy Russian Scientists and Men of Letters

To the Editor of Chemical & Metallurgical Engineering

SIR:—In several of your editorials you have called attention to the suffering Russian scientists, suggesting that something be done to relieve their sad condition. I do not know whether there were any responses to your call, but if there were not it may not be for lack of sympathy or desire to help the starving Russian scientists, but rather on account of the uncertainty whether the help would reach them.

In view of the above I wish to call attention to the possibility of sending food products now through the American Relief Administration (Hoover's organization). This organization accepts money in units of $10 and through its agents in Russia delivers an equivalent in food products to the persons designated. Food can be sent to individuals or to the Mutual Aid Society of Scientists and Men of Letters. The address is as follows: House of Science, Basseynaya 11, Petrograd, Russia. Individuals can be reached at the same address.

Food remittance blanks can be obtained in most of the banks or directly from the American Relief Administration, Russian Food Remittance Department, 42 Broadway, New York City. IVAN M. BREGOWSKY.

Chicago, Ill.

The Manhood of Humanity

To the Editor of Chemical & Metallurgical Engineering

SIR:—I rather feared that somebody would take exception to my praise of Korzybski's book called "The Manhood of Humanity, or Human Engineering." It has been the subject of considerable disagreement between just such competent and level-headed persons as Mr. McDonald and Prof. Cassius J. Keyser. Then there are the rest of us who, without distinction as to our merits as thoughtful readers, seem to take sides about it.

I think all will admit that human society is in a bad way. There is a distressing lack of ideals in the public mind. The supreme need that we fulfill our obligations is not well developed in these days. I believe it will be generally agreed that society needs quickening in the consciousness of its obligations more than in any other respect.

To some of us this idea of time-binding, this requirement that we add our contribution to the work of the dead and pass it on to coming generations as the only way to maintain humanity in a state of progress, seems important. Time-binding does not present the requirement as a virtue, but rather as a necessity. It shows that if we destroy the work of the dead we rob future generations, and we become ghouls, as Count Korzybski puts it, who live on the dead. The distinction between what is good for humanity and what is bad for it is older than history. The book, to some of us, makes this distinction, which has grown rather cloudy under the blinding rages of war, clear and living again. This is important, even if only a few gather such light from it.

New York City. ELLWOOD HENDRICK.

The Electric Melting Furnace

To The Editor of Chemical & Metallurgical Engineering

SIR:—A scientific innovation is doomed to pass through a definite cycle of ups and downs before it finally comes to rest on a firm foundation of real and rational utility. Brought to light to a circle of the favored few, it is for a time an object of wonder, almost of veneration. Then follows the period of ridicule. The public seizes upon it as a curiosity, a dream creation, a plaything for highbrows. But practical? No!

Then some firm of established reputation adopts the new thing after careful and laborious investigation. A whirlwind of popularity ensues. The new invention immediately becomes a panacea for all evils. Wild advertising makes it a household world. It is invested with miraculous virtues it does not possess. It becomes the popular savior of a troubled technical world. Everyone who can possibly find or imagine a use for it quickly adds his name to the list of anxious purchasers.

Then the bubble bursts! It is found that brains and experience are adjuncts to success. The thing that required only cheap unskilled labor—according to the advertisements—is found to be as stubborn as a balky mule, and failure after failure is registered.

Finally popularity wanes, and the new invention finds its way to the hands of the few who know its uses, its

limitations and its difficulties. It has found its niche in the scheme of industry.

At the present time, the electric furnace is riding the crest of the wave. Tales of the electric furnace find their way into the transactions of our technical societies. Journals carry highly colored advertising. Purchasing agents will pay premiums for "electric steel."

The electric furnace is an ideal method for certain types of melting. Oxidation is almost negligible. Accuracy in composition can be obtained with reasonable certainty. The electric furnace is an admirable superheater. Heats can be held with safety at almost any range required. The electric furnace may be depended upon not to burn up good material that may be put into it. But while it proves to be a first-class nurse for healthy material, it is a poor doctor for sick material.

If we cut through the mass of variations heaped upon the principle of electric melting, what is left? If we disregard phase, single and multiple arcs, direct and indirect, electrodes top or side, vertical or inclined, what does the electric furnace become? Simply a crucible heated internally instead of externally. A crucible independent of impure fuel, and independent of careless firemen.

Every steel man knows that he cannot make good steel from poor materials in an externally heated crucible. Then by the simple expedient of changing the fuel, how does he expect to perform that miracle in an electric crucible? Yet that is just what many persons expect to accomplish. What wonderful cleansing power can there be in electric heat? The argument has been advanced that the atmosphere of an electric furnace is neutral, therefore no oxidation can take place. I admit that the electric furnace establishes a kind of quarantine against the atmosphere. A quarantine will probably protect against the entrance of outside poisons, but can a quarantine cure the effect of poisons already within?

In other words, can the electric furnace hope to reduce metal that is oxidized before it goes into the furnace? Will electric heat reduce rust? This is almost an impossibility in any other kind of furnace. We know that rusty, dirty scrap is the cause of endless trouble in the open hearth. I should like to see a heat of high-grade cast iron made in an electric furnace from a charge of burned grates. It has been contended that the electric furnace, because of a neutral atmosphere, permits heat to be held for a long time, when dirty baths can be cleaned by gravity. It may be possible to raise a goodly portion of contained fusible slag, but will infusible finely divided sonims rise? Will absorbed gases free themselves? Passing from theory to practice, why are foundries melting with electricity so liberal with aluminum when casting their metal? And why are so many porous castings poured from electric steel?

It is not my intention to ridicule the electric furnace. It is a valuable piece of equipment. But it is essentially a crucible and nothing else. If we restrict the use of the electric furnace to the production of alloys—its original field, where heat is the main essential—and to material of crucible quality—simple, safe melting of first-class materials—and if we take advantage of the ability of the electric furnace to produce crucible quality in quantity, then we shall have found the niche for this invention.

HENRY TRAPHAGEN.

Toledo, Ohio.

EDITOR'S NOTE.—Mr. Traphagen's letter is interesting as a protest against blatant exploitation of mediocre or even inferior material, simply because it has come from an electric furnace. He is doubtless correct in his inferred complaint that the electric furnace, *as ordinarily run,* will not reduce oxide; with no particular effort made to seal all openings, the furnace atmosphere is often powerfully oxidizing. Nor is there any wonderful cleansing power in electric heat.

However, the electric furnace has one distinct advantage which the crucible has not, and that is that the skilled metallurgist can make up various slags on his metal, and thereby submit the molten bath to a sequence of chemical reactions (aided by mechanical stirring) which are impossible in the crucible. This is unquestionably the reason why good open-hearth steel can be bettered in an electric furnace, *properly operated.*

Lacking a precise and convenient analysis for gases in metal and in view of our considerable ignorance on the constitution of slag inclusions, we can only infer the actual effect of oxide on steel. It is in consonance with the principles of physical chemistry to suppose that a steel refined under a calcium carbide slag free from metallic oxides, will itself be practically cleansed of oxide inclusions. We do know that when such steel, made of reasonably good material, is properly cast and forged it exhibits unexceptionable tensile properties and beautiful silky fractures, with little or no evidence of transverse brittleness. Few open-hearth steels can even approach this.

Sulphuric-Acid Air Lift

To the Editor of Chemical & Metallurical Engineering

SIR:—I have read with interest the letter of Mr. Imison regarding the Bihn-Jones automatic device for elevating sulphuric acid by compressed air, referred to in the article by Mr. Fairlie on the sulphuric-acid industry.

This device is for all practical purposes identical with the Plath Automatic Acid Elevator that has been manufactured in chemical stoneware by the General Ceramics Co. since 1907 for moving any kind of corrosive liquid. It was fully described in a paper presented by Dr. G. Plath before the Verein deutscher Chemiker on April 16, 1902. It was at that time manufactured by the Deutsche Ton & Steinzeugwerke of Berlin and had then to my knowledge already been on the market for some considerable time.

This would indicate that the idea originated with Dr. Plath and was possibly adopted by Mr. Barnes to construction in metal. Whether this is the case or not, it is quite certain, as Mr. Imison implies, that the credit is not due to Bihn-Jones.

PERCY C. KINGSBURY.

New York, N. Y.

Greensand as a Source of Fertilizer Potash

To the Editor of Chemical & Metallurgical Engineering

SIR:—In "Greensand as a Source of Fertilizer Potash," published on page 1056, vol. 25, the weight of mother liquor, caustic soda (37.5 deg. Bé.) was given as 90 grams. This should read 900 grams.

New York City. R. NORRIS SHREVE.

Study of Gas From Destructive Distillation of a Mixture of Water-Gas Tar and Coal

To the Editor of Chemical & Metallurgical Engineering

SIR:—The heading of the fourth column of Table III in my article, published in the issue of Feb. 22, should read "Theoretical Alcohol Equivalents in Grams" instead of "Hydrocarbons in Grams."

Pittsburgh, Pa. RALPH L. BROWN.

The Explosibility of Ammonium Nitrate

A Review of Its Known Properties and Behavior and a Study of Accidents in Which It Was Involved—These and the Results of Recent Scientific Tests Form the Basis of Important Conclusions Regarding Transportation, Storage and Use of Ammonium Nitrate

By CHARLES E. MUNROE
Chairman, Committee on the Investigation of the Explosibility of Ammonium Compounds, National Research Council

THE very severe and most disastrous explosion which occurred on Sept. 21, 1921, in the nitrogen fixation factory at Oppau, where ammonium nitrate was being produced on a large scale, has led to the publication of many articles indicating a lack of precise knowledge of the properties of this compound. Nothwithstanding the many records in the literature and the relatively recent and definite statement of the Bureau of Mines,[1] these articles often manifest a rather general feeling of surprise at the fact that ammonium nitrate is, under certain circumstances, explosive *per se.* In view of the long-continued use of ammonium nitrate and its very rapidly growing importance in our industries, and in view, further, of the fact that a lack of precise knowledge of the properties and behavior of this substance may lead to unnecessary and burdensome restrictions being placed upon its manufacture, transportation, storage and use, it seems advisable to review the case for ammonium nitrate and, in doing so, to present the results of recent tests that have been placed at my disposal.

Uses of Ammonium Nitrate

For Producing Nitrous Oxide: With the identification of nitrous oxide (laughing gas) by Priestley in 1776, the discovery of its physiological effects by Davy in 1800 and its application as an anæsthetic by the American dentist Dr. H. Wells in 1844, this substance, produced by the thermolysis of ammonium nitrate, came into a continually extended use in dentistry and in more recent years as a component of anæsthetics for other purposes. Statistics of ammonium nitrate for this use are difficult to obtain, since, though from the standpoint of use this is a very important industry, from the standpoint of monetary value it is a very minor one. The U. S. Census of 1905[2] reported a consumption of 75,894 lb. of ammonium nitrate for the production of nitrous oxide. From the circumstances of the case it is believed that this figure was too low and there is little doubt that at the present time the amount so consumed is many times this.

In Explosives: It is obvious that ammonium nitrate, like saltpeter and other nitrates, readily and easily forms explosive mixtures with combustible substances. Many such mixtures have been proposed and a considerable number used. As early as May 31, 1867 (the same year in which Nobel obtained his English patent for dynamite), a Swedish patent was issued to Ohlson and Norrbin for an explosive composed of a mixture of ammonium nitrate, nitroglycerine and carbon. The hygroscopicity of ammonium nitrate was an obstacle to the use of such compositions, but when, on Feb. 10, 1885, U. S. Patent 312,010 was issued to R. S. Penniman for "Protected Nitrate of Ammonia for Use in Explosive Compounds," a new impetus was given to the use of this salt, for, by coating the grains of the ammonium nitrate with petrolatum, Penniman waterproofed them sufficiently for economic use. Partly because of this and partly from other causes the use of ammonium nitrate in explosive compositions, and especially the so-called "safety explosives," has steadily increased, so that, according to Howell,[3] 90 per cent of all "permissible explosives" sold in the United States in 1920 belonged to the ammonium nitrate class and that the total quantity of ammonium nitrate in them aggregated 31,831,000 lb. It is probable that the quantity of ammonium nitrate used in the 229,112,084 lb. of high explosives other than "permissibles" sold in this country in 1920 greatly exceeded this amount.

During the late war ammonium nitrate found wide acceptance as a component of the amatols, ammonals, sabulites and many other explosive compositions that were extensively used in military operations. Considering all the circumstances, Crowell's statement[4] that before the Great War 58,000,000 lb. of ammonium nitrate was used annually in the manufacture of commercial explosives in this country and that our total capacity for the production of this salt at the time of the signing of the armistice was 20,000,000 lb. per month is well within the mark.

Ammonium nitrate in the explosives industry affords a convenient and economic means of utilizing the weak nitric acid recovered from the spent acids of this industry.

As a Fertilizer: Ammonium nitrate contains upward of 35 per cent of fixed nitrogen available as plant food. One half of this nitrogen is present in the nitric form, and the other half in the amino form. Compared with other substances used as fertilizers ammonium nitrate is found to contain more than twice the nitrogen content of sodium nitrate, nearly 14 per cent more nitrogen than ammonium sulphate, practically the same nitrogen content as calcium cyanamide and but about 12 per cent less nitrogen than urea, this comparison being based upon the assumption that each of the compounds named is pure and in the anhydrous condition. Ammonium nitrate possesses the advantage over ammonium sulphate, calcium cyanamide and urea in that, while the entire nitrogen content of each of these three bodies is in the amino condition, one-half of that of ammonium nitrate is in the nitric condition, and over sodium nitrate in that, while containing about 1 per cent more of

nitric nitrogen than sodium nitrate, it possesses in addition nearly 17.5 per cent of amino nitrogen.

The hygroscopic and deliquescent properties of ammonium nitrate have militated against its use as a fertilizer, since they cause it to tend to cake and liquefy in storage, transportation and use. These characteristics also interfere seriously with the efforts of the farmer to spread the material on the fields, and of the manufacturer to make use of it as a component of compounded fertilizers. With the development of the Haber and Claude processes for the fixation of nitrogen, ammonium nitrate may be produced in a pure condition in enormous quantities and there is little doubt that in the fertilizer industry, as has been done in the explosives industry, means will be devised by which its objectionable characteristics will be so overcome that its proved valuable qualities as a fertilizer may be availed of. It is to be noted that the proposed contract of Henry Ford for Muscle Shoals calls for an annual production of 110,000 tons.[5]

Explosiveness of Ammonium Nitrate

In the seventeenth century Glauber knew ammonium nitrate, which he styled nitrum flammans[6]. Gmelin[7] styled it also flammender saltpeter and cites Marchand as stating that "when rapidly and violently heated, as for instance when thrown on a red-hot porcelain plate, it burns with a pale yellow light and very slight noise, and gives off water, nitrous and nitrogen gas. It explodes when thrown on red-hot charcoal." In Turner's Chemistry[8] it is stated that "when this salt is exposed to fire, it liquefies, emits aqueous vapor, dries and detonates." But the most complete investigation was made by Berthelot.

Berthelot's Researches

In 1869 Berthelot published his "Nouvelle recherches de thermochimie,"[9] in which, on pages 77 to 82, he treated of the decomposition of ammonium nitrate by heat, pointing out that the reaction taking place might be such as to absorb heat or to evolve heat and that the character of the reaction was determined by the heat applied according to whether the temperature is moderate or is increased rapidly.

He also states, on page 78, that when a crystal of ammonium nitrate is thrown into a red-hot crucible it decomposes with a flash of light, indicating the disengagement of considerable heat.

Berthelot returned to the consideration of this topic in 1875 in his "Sur les oxydes de l'azote,"[10] where, on page 188, he recognizes five different modes of decomposition of ammonium nitrate, and again in 1877 in his "Decomposition pyrogénée de l'azote,"[11] where he demonstrates the sublimation of ammonium nitrate and points out errors in the data of his former papers.

The results of his continued investigations are brought together and systematically presented in his "Sur la force des matières explosives d'apres la thermochimie,"[12] where, on pages 20 to 23 of vol. 1, we find the following:

Thermal Decompositions: The decompositions which ammonium nitrate undergoes under the influence of heat are seven in number, as follows:

1. The dissociation or partial decomposition of fused or even gaseous ammonium nitrate into gaseous nitric acid and ammonia, which seem to be first produced and at a low temperature, as follows:

$$NH_4NO_3 = HNO_3 + NH_3$$

It takes place necessarily with absorption of heat—namely: —41,300 cal. when the solid nitrate is used, and about —37,000 when the salt is fused.

2. The formation of nitrogen monoxide (laughing gas) from ammonium nitrate at a higher temperature, and when the heat is carefully regulated. The reaction

$$NH_4NO_3 = N_2O + 2H_2O \text{ (gas)}$$

develops +10,200 cal. for the solid nitrate and about +14,000 cal. for the fused salt.

If the salt be supposed to have been previously decomposed into gaseous nitric acid and ammonia, and the reaction to have taken place between these two compounds with the formation of nitrogen monoxide, as follows:

$$HNO_3 \text{ (gas)} + NH_3 \text{ (gas)} = N_2O + 2H_2O,$$

then this reaction would develop +51,500 cal.

3. When rapidly heated, the explosive decompositions, properly so called, of ammonium nitrate take place; one of them produces nitrogen and oxygen, as follows:

$$2NH_4NO_3 = 2N_2 + O_2 + 4H_2O \text{ (gas)}$$

This reaction develops from the solid salt +30,700 cal.; and from the fused salt about +35,000 cal.

4. Or nitrogen and nitrogen dioxide may also be formed, as follows:

$$2NH_4NO_3 = N_2O_2 + N_2 + 4H_2O$$

and +9,200 cal. is given off when the salt is solid and about +13,000 cal. when it is fused.

5. Heat is also liberated when ammonium nitrate gives rise to nitrogen, water and nitrogen tetroxide

$$4NH_4NO_3 = 3N_2 + N_2O_4 + 8H_2O$$

+29,500 cal. being set free from the solid salt, and +33,500 cal. from the fused salt.

6. The ammonium nitrate may also be conceived as being transformed into nitrogen, water and nitrogen trioxide.

$$3NH_4NO_3 = 2N_2 + N_2O_3 + 6H_2O$$

This reaction liberates +23,300 cal. from the solid salt, and about +27,000 cal. from the fused; but it never takes place alone, as nitrogen trioxide exists in the dissociated state only in presence of nitrogen dioxide and nitrogen tetroxide.

7. Lastly, ammonium nitrate can be resolved into gaseous nitric acid, nitrogen and aqueous vapor under certain influences such as that of spongy platinum

$$5NH_4NO_3 = 2HNO_3 + 4N_2 + 9H_2O$$

yielding +33,400 cal. from the solid salt and about +37,500 cal. from the fused.

Effects of Temperature and Rapidity of Heating: These different modes of decomposition of ammonium nitrate, which may be separate or simultaneous, or, more exactly, the predominance of any one of them, depend on the relative rapidity and on the temperature at which decomposition is produced. This temperature is not fixed, but is itself subordinate to the rapidity of heating. It has been established by a great number of observations that each mode of decomposition of a given substance commences at a certain temperature and in a given time a limited weight of substance is decomposed.

Special stress is laid upon the singular property which ammonium nitrate possesses of undergoing several distinct modes of decomposition, according to the rapidity of heating and the temperature to which the substance is raised. Of these decompositions, some take place with liberation of heat, others with absorption of heat.

On pages 182 to 187 of vol. 2 Berthelot further discusses this topic and from the thermochemical data deduces the temperature and pressure developed in the decomposition of ammonium nitrate for each of the several reactions it undergoes.

Attention is first called to the fact that this salt begins to decompose at a temperature a little above 100 deg. C.

[12] Third edition in two volumes, Paris, Gauthier-Villars, 1883.

while at the same time subliming in part. At about 200 deg. C. it is separated into nitrogen monoxide (laughing gas) and water without, however, there being a fixed temperature at which this reaction takes place. If the salt is superheated, and especially from 230 deg. C. upward, the decomposition accelerates itself more and more (nitrum flammans) and it ends by becoming explosive, while at the same time the salt becomes incandescent.

By thermochemical calculations Berthelot finds the theoretical temperatures developed under constant volume and the pressures developed for a given mass of the nitrate decomposed in its own volume with the water produced in the liquid or the gas phase. The highest results given are for reaction 3, in which the theoretical temperature is 1,501 deg. C. and the pressures, with water liquid, 3,200 kg. per sq.cm., and with water gaseous, 11,200 kg. per sq.cm. For reaction 4 the theoretical temperature is 518 deg. and the pressure, with water gaseous, 4,860 kg. per sq.cm. For reaction 2 the theoretical temperature is 555 deg. C. and the pressure, with water gaseous, is 4,500 kg. per sq.cm.

Explosion in Confinement

The direct explosion of ammonium nitrate *per se* through the use of an initiating agent was effected by Lobry de Bruyn[13] in 1891. For this purpose he employed a shell of 8-cm. caliber, weighing 7 kg., and a charge of about 2 kg. When the shell was loaded with ammonium nitrate and fired with a detonator containing 3 g. of mercury fulminate, the shell was burst and but sixty-two fragments, weighing about 6 kg., could be recovered. In a second experiment the shell was charged with 180 g. of ammonium nitrate primed with about 10 g. of bellite and fired by a detonator containing 1 g. of mercury fulminate. The shell was so comminuted by the explosion that but 230 fragments, weighing altogether 2.75 kg., could be recovered, as the rest of the shell had been reduced to powder.

In 1907 Lheure[14] compressed ammonium nitrate into cartridges under a pressure of 20 kg. per sq.cm. Three such cartridges, weighing 50 g. each, were confined in a bore hole in clay, by tamping them with 6 dm. of stemming, and they were fired by a piece of cordeau, 7.3 mm. in diameter, which traversed all three of the cartridges. The detonation of the ammonium nitrate was complete.

Pressure Developed: In his address before the Royal Institution on "Some War Developments of Explosives" Sir Robert Robertson[15] gave a table of pressures developed by ammonium nitrate, amatols and TNT on explosion as determined by Bertram Hopkinson's pressure bar,[16] in which it appears that while TNT developed on explosion a pressure of 55 tons per sq.in. in 0.5×10^{-5} seconds, ammonium nitrate developed a pressure of 12.5 tons in the same time.

Accidents Involving Ammonium Nitrate

The foregoing record shows beyond question that ammonium nitrate under certain circumstances is, by itself, explosive. This is true of may substances occurring in commerce, some of which are quite widely used. The question arises, Is ammonium nitrate to be regarded as an explosive and treated as such under all circumstances? We may get the answer by consideration of accidents in which it was involved and from the results of tests.

There have been fires in which ammonium nitrate was involved, and in none of them, so far as the record goes, was there any explosion unless some other explosive was involved or unless material which could form an explosive mixture with ammonium nitrate was present. Thus at Barksdale, Wis., a building containing 30,000 lb. of ammonium nitrate stored in barrels on the floor was completely burned, yet there was no explosion and some of the ammonium nitrate was left unconsumed. But the most important instance, because of the quantity involved, is that of the steamer Hallfried.

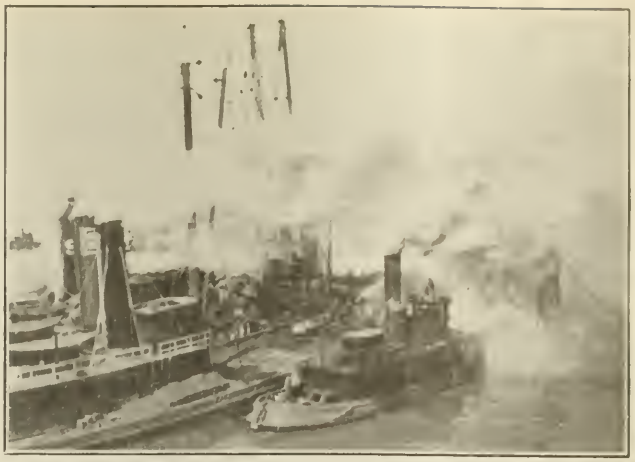

FIG. 1—EXTINGUISHING FIRE ABOARD THE STEAMER HALLFRIED*

Fire on Steamer Hallfried

At about 12:40 noon, on April 14, 1920, a fire broke out in the forward compartment of the steamer Hallfried as she lay at Pier 5, Bush Docks, Brooklyn, N. Y., discharging cargo from all four of her compartments onto lighters alongside and when she had already discharged about one-third of her cargo. She had sailed from Menstad, Norway, with a mixed cargo of raw skins, paper, ammonium nitrate, nitrate of soda and some chlorate, and it is believed the latter was the cause of the outbreak. There were on board 8,460 casks containing about 4,230,000 lb. of ammonium nitrite distributed among compartments 1, 2 and 3. Of this amount 3,111 casks were burned up in the ship and 778 casks

FIG. 2—STEAMER HALLFRIED AFTER THE FIRE WAS EXTINGUISHED

*Photos reproduced in Figs. 1 and 2 were supplied by the Merritt & Chapman Derrick & Wrecking Co., which extinguished the fire.

on the lighters. After the extinction of the fire 2,077 casks, most of which were sound, were discharged from compartment 3. All that had not been discharged from compartments 1 and 2 before the fire were destroyed. Although the fire was a fierce one and 1,944,500 lb. of ammonium nitrate was destroyed in it, there was no explosion.

In discussions of the Oppau explosion frequent allusions have been made to explosions at the Oakdale plant of the Aetna Co. and the Repauno plant of the du Pont Co., as well as to the explosion at Morgan, N. J. The Oakdale and Repauno explosions have a special interest in that they occurred during the manufacture of ammonium nitrate and its process of crystallization.

Repauno Explosion

The circumstances of the Repauno explosion are described as follows by the director of the chemical division of the company in a private communication:

> At 10 p.m. on Jan. 14, 1916, an explosion occurred in the ammonium nitrate evaporating and crystallizing plant of E. I. du Pont de Nemours & Co., located at Repauno Works, Gibbstown, N. J., inflicting heavy damage to the plant property and resulting in the loss of one life and more or less serious injuries to twelve employees, none of whom suffered permanent disability.
>
> The plant consisted of a row of five evaporating pans and a row of five crystallizing kettles located parallel to each other and numbered consecutively from right to left when facing the pans with back to the kettles. The evaporating pans were separated from one another by a space of approximately 3 ft. and the kettles by a space of approximately 3 ft. and the row of pans was approximately 15 ft. distant from the row of crystallizing kettles. At the time of the explosion, evaporating pan 3 contained a charge of approximately 4,000 lb. of ammonium nitrate which had been about completely evaporated and was ready to be discharged into crystallizing kettles 1, 2 and 3. Evaporating pan 5 contained a charge of ammonium nitrate liquor which was being evaporated, the actual ammonium nitrate content of which was about 2,000 lb. Evaporating pans 1, 2 and 4 were empty.
>
> Crystallizing kettles 2, 3 and 4 each contained approximately 1,000 lb. of ammonium nitrate. Kettle 1 had just been emptied and kettle 5 was not in use.
>
> The explosion occurred in evaporating pan 3, as evidenced by a crater about 5 ft. in depth directly beneath this pan, and so far as could be ascertained none of the other ammonium nitrate exploded. The steam pressure in the coils of pan 3 was probably in the neighborhood of 100 lb. per sq.in. at the time of the explosion. For several days the atmospheric temperature had been high and the humidity very great, and on the night of the explosion there had been a sudden drop in temperature. It seems probable that there was a stoppage of the air supply to the agitating pipes in the evaporating pans, due to frozen water in the supply pipe, and that due to this failure of the air supply, molten ammonium nitrate was forced into the agitating pipes, under which confinement rapid local decomposition took place, which finally extended to the entire charge.

The conditions for overheating in the Repauno accident are analogous to those in the manufacture of laughing gas except that the latter affords an easier opportunity for that rapid application of a high-temperature source of heat which Berthelot states is likely to bring about explosive decomposition. Yet I have found but a single record of such an explosion, and this by Daniel,[1] who cites an accident at Kensington, March 20, 1896, following the heating of 18 lb. of ammonium nitrate in an enameled iron retort by Dr. Orchard, a dentist, for the purpose of producing laughing gas, when explosive decomposition set in and the plant was wrecked.

[1] "Dictionnaire des matières explosives," J. Daniel, Paris (1902), p. 458.

Oakdale Explosion

The following description of the Oakdale explosion was supplied to the writer by Superintendent Johnson:

> The accident occurred on Sept. 15, 1916, at 8:50 p.m. An explosion occurred in one of the pre-boiling tanks. There were three or four of these tanks, which sat on the side hill between the neutralizing tanks and the graining bowls. These tanks were approximately 4½ ft. wide, 3½ ft. deep and 8 ft. long. They were old crystallizing tanks from the Carnegie TNT plant. The explosion tore one of these tanks into small bits, the largest piece we found being three-quarters of a mile from the explosion. It weighed 173 lb. This was near the Greggs Station. Another of these tanks was found up the hill above the neutralizing tanks near the boiler house, or a distance of about 25 ft. higher on the hill, back approximately 50 ft. from its foundation. These tanks were ordinary boiler plate and were equipped with cast-iron coils, put together by rust joints.
>
> For some weeks prior to this we had been trying to produce ammonium nitrate of 99 per cent or better purity for the government. We were using ammonia liquor, I believe, which was shipped us by The Barrett Co. or the Semet-Solvay Co. The nitric acid was a mixture of the weak from the still acid and the recovered nitric from the TNT spent. Only a very small proportion was still acid. Inasmuch as we had not been very successful in obtaining a high grade of ammonium nitrate, we decided about 10 days prior to the date of the accident that it would be necessary to empty and wash out the settling tanks, which were 10 x 10 wooden tanks. These settling tanks had been washed out and the charge that blew was the first one to be boiled down after they had been cleaned out. The charge was put into the tank some time during the day. It occurs to me that it was before noon. As we were very anxious concerning the results, Mr. Hutchinson, then acid foreman, and I made several visits and spent quite some time watching this particular charge. I was informed by Mr. Hutchinson that it was necessary to extinguish a small blaze on the charge several times during the day, although the liquor apparently had been thoroughly settled, judging from the appearance and the length of time, having been better than 4 days.
>
> At the investigation after the accident, at which Messrs. Fox, Crewe and one or two others were present, it was decided that the accident was due to the TNT in the acid. While this may have been the explanation, Mr. Diehl and I concluded, after conversation with a couple of prominent chemistry instructors, that the accident was due to the presence of unstable nitrites, due to the excessively high oxides in the acid. This of course is usually found to be the condition of nitric acid recovered from TNT, and the assumption was based on some German literature to which reference has been made. I regret that I am unable to furnish these references at this time. Either explanation, however, is only theoretical, as the exact reason is not known. My reason for believing the latter theory was that the neutralized ammonia liquor had such a clear appearance that it seemed to me that this was a more reasonable explanation.
>
> The explosion was felt for a distance of about 15 miles away, which will give some idea of the intensity of the blow. I think that approximately 3,000 lb. of nitrate of ammonia was in the exploding charge.

It might be well to point out that in both the Repauno and Oakdale cases weak nitric acid recovered from TNT waste acid was being used in manufacturing the ammonium nitrate. It is known that such weak acid contains nitro bodies and it is possible that these nitro bodies may have had something to do with initiating the explosions.

Morgan Explosion

Among the great disasters in which ammonium nitrate played an important part was that which occurred at the plant of the T. A. Gillespie Loading Co., Morgan, N. J. This started with a fire in the extruding plant for loading amatol into shells, which was situated in the northwest corner of the tract of 2,600 acres occupied by this plant. The fire started just before 8

p.m. Friday, Oct. 4, 1918, and continued to rage until the night of Oct. 5. At the time the fire broke out there was assembled within the above-mentioned area 30,855,076 lb. of explosives, some stored in magazines and some in loaded shell, part of the latter being in dumps on the ground and part on railway cars. Shortly after the fire started shells began to explode, many of them being projected to a distance before they exploded, and a fitful bombardment continued through Oct. 6, even after the general conflagration had ceased. In this disaster 12,155,839 lb. of explosive was destroyed. Among the materials at Morgan was upward of 9,000,000 lb. of ammonium nitrate. I visited the scene of this disaster on Tuesday, Oct. 8, as soon as it was at all possible to permit of inspection, and noted particularly the locations at which ammonium nitrate had been stored, observing in instances partly burned barrels and heaps of fused material surrounding barrels of this nitrate that were perfectly intact, but finding special interest in the enormous craters excavated at sites where storehouses containing ammonium nitrate had been located. One of these craters 150 ft. long, 140 ft. wide and 30 ft. in depth was exceeded, in one dimension only, by that at the site of a large dump of loaded shell, and also that at a place where three cars loaded with TNT had been parked.

There is no doubt whatever that the ammonium nitrate that was in storage at the locations cited detonated very completely. It is equally certain that ammonium nitrate stored at other sites within this area did not detonate or even explode, although exposed to fire and to the shock of the many heavy detonations which occurred within this area. Where so many factors obtain as in this case it is not possible to determine definitely the cause of the detonations of the ammonium nitrate that did occur, but considering all the circumstances it seems not improbable they were due to the explosion within the ammonium-nitrate storehouses of high-explosive shell loaded with amatol.

I have added to the information gathered in my visit by perusal of Congressional documents and the excellent report by F. Hawkes. The latter was in intimate touch with the Morgan plant from the beginning of its construction and throughout its operation. He was at the plant throughout the period of its destruction and observed its progress from its beginning to the end. He states that "all major explosions at the plant were preceded by flames which could be seen mounting higher and higher, in each case culminating in a huge column of smoke and flame, the shock of detonation reaching us a little time afterward." "It is certain that actual detonations of large amounts of ammonium nitrate took place at the destruction of the Morgan plant, these detonations being preceded by fierce fires, during the time when amatol-loaded shells were being projected or had been projected from other parts of the plant." "There were certainly no explosions of ammonium nitrate previous to those which occurred during the destruction of the plant."

Recent Tests of Ammonium Nitrate

I now present the results of tests which I have compiled from a mass of data supplied to me by F. C. Zeisberg of the du Pont company, covering not only the solid nitrate of commerce, but also the molten nitrate such as is found in the crystallizing pans.

Effects of Heating: Because of the explosions that had occurred in crystallizing pans during the manufacture of ammonium nitrate, tests were made of both the anhydrous and the hydrous material in the molten condition, the first observations made being as to the effect of heat upon it. For this purpose 10 lb. of the salt, containing 99.11 per cent of ammonium nitrate and 0.08 per cent of moisture, was placed in a 10-qt. enameled kettle, a standardized base-metal thermocouple inserted in the salt, the kettle with its contents placed on an improvised cylindrical stove, in which was a coke fire, and heated. The temperatures in the mass were read by a millivoltmeter.

In the first tests the mass attained a temperature of 29 deg. C. in 1 minute and white fumes in small quantity were given off. In 4 minutes more the temperature had risen to 72 deg. C. and white fumes were given off in considerable quantity. In 1.5 minutes more the temperature had risen to 261 deg. C. and red fumes appeared mixed with the white ones. One minute later

FIG. 3—BURNING TEST WITH THREE BARRELS, EACH CONTAINING 500 LB. AMMONIUM NITRATE

the temperature observed was 289 deg. C. and at that point yellow fumes appeared mixed with the white. In 1.5 minutes more the temperature noted was 348 deg. C. and the fumes had begun to lessen. One minute later, or 10 minutes from the start, a temperature of 375 deg. C. was reached and the fumes had ceased. Close examination showed that all of the ammonium nitrate had disappeared, leaving the kettle empty. There was no explosion.

This test was twice repeated with some slight variations, but, though analogous rapid rises in temperature and volatilization of the ammonium nitrate, accompanied at the higher temperatures by red and yellow fumes, due undoubtedly to nitrogen oxides from thermolysis of the nitrate, occurred, there was no detonation in any instance. The only approach to an explosion was in test 2, in which an 8-in. length of 1-in. iron pipe, filled with freshly crystallized ammonium nitrate and closed at both ends with iron caps, which were screwed on them, was imbedded in the charge of ammonium nitrate in the kettle to serve possibly as a primer for the latter, for at the expiration 11 minutes and when the temperature had reached 318 deg. C. there was a slight report and flash. It was found that the pipe had been split, was appre-

ciably shattered, as was one of its caps also, and that the kettle was split, while some of the ammonium nitrate was found scattered on the ground. This latter suggested that the flash observed may have been caused by the projection of molten nitrate into the fire.

FIG. 4—IMPACT TESTING MACHINE

Sensitiveness of Molten Nitrate: Aqueous solutions of ammonium nitrate were evaporated to the crystallizing point, the temperature raised to insure complete liquefaction, and detonators or blasting gelatine exploded in the mass. The tests were conducted in open kettles and 10-lb. charges of ammonium nitrate were used. Although No. 8 detonators, singly and in groups of three, and 100-g. masses of explosive gelatine, primed with cordeau, were exploded in these "hot liquors," there was in no instance any approach to detonation on the part of the ammonium nitrate.

Pendulum Friction Test: Using 10 g. of fine-grained nitrate, containing 99.11 per cent ammonium nitrate and 0.08 per cent of moisture, on the steel anvil and a fall of 2½ m. for the steel shoe, negative results were obtained in 190 tests. There was no explosion or local crackling in any case.

Impact Test: In ten tests of the above-mentioned ammonium nitrate no explosions occurred when a weight of 20 kg. falling through a meter in height impinged upon the nitrate confined between steel surfaces.

Tests of Explosibility: Tests of explosibility were made on ammonium nitrate from different sources by firing a cartridge of blasting gelatine, exploded by cordeau, in contact with the nitrate.

FIG. 5—PENDULUM FRICTION TESTING MACHINE

EXPLOSIBILITY TESTS

Kind of Am. Nitrate	Moisture Content Per Cent	Weight of Am. Nitrate	Weight of Blasting Gelatine	Result
German "as received"	0.26	15 lbs.	240 grams	Detonated
Brünner-Mond, "as received"	0.84	15 lbs.	240 grams	Partial detonation
No. 2 cast	1.45	40 lbs.	243 grams	Detonated
German, "as received"	0.16	135 lbs.	243 grams	Detonated and produced crater 12 ft. in diameter and 4 ft. deep.

Effect of Admixture With Ammonium Sulphate

Test of mixtures of No. 3 ammonium nitrate made from German ammonia with ammonium sulphate were made in a similar manner to those just described, except that the charge was placed on a lead block, as described below. The two salts were mechanically mixed "dry."

FIG. 6—DETONATION TEST OF 40-LB. KEG OF AMMONIUM NITRATE BY 240 GRAMS (½ LB.) CARTRIDGE OF BLASTING GELATINE

EXPLOSIBILITY OF MIXTURES OF AMMONIUM NITRATE AND AMMONIUM SULPHATE

Parts of NH_4NO_3	Parts of $(NH_4)_2SO_4$	Weight of Blasting Gelatine, Grams	Result	Compression of Lead Block, Inches
90	10	100	Detonation	¼
90	10	75	Detonation	¾
90	10	50	No detonation	None
80	20	100	Detonation	¼
80	20	75	Detonation	½
80	20	50	No detonation	None
70	30	100	No detonation	None
60	40	100	No detonation	None

Sensitiveness to Detonation by Blasting Gelatine

Tests of sensitiveness of ammonium nitrate to detonation by blasting gelatine were made by placing 400 g. of the dry nitrate in a beaker which rested on a lead block 4 in. high and 2¼ in. in diameter. The firing was done with different known weights of blasting gelatine exploded in the ammonium nitrate by means of cordeau

SENSITIVENESS OF AMMONIUM NITRATE TO DETONATION BY BLASTING GELATINE

100	Detonation	⅝
75	Detonation	½
50	Detonation	⅜
25	No detonation	None

detonant and the effect on the lead block measured. The ammonium nitrate used was No. 3 made from German ammonia.

Relation of Temperature to Sensitiveness to Explosion

The tests were made by placing 2-lb. charges of fine-grained ammonium nitrate, 99.1 per cent pure, in tin

FIG. 7—CONDITION OF KEGS AND CONTENTS OF AMMONIUM NITRATE AFTER FIRE AND WATER TESTS

Three kegs were supported over open fire in a closed room and were extinguished after 15 minutes through operation of automatic sprinkler device.

cans 4 in. in diameter by 5 in. in height, heating the can and contents in a paraffine bath to the desired temperature, placing this system on a lead block 2¼ in. in diameter by 4 in. in height, then imbedding in the ammonium nitrate one or more No. 8 electric detonators and firing them. The results obtained were as follows:

Temperature of Nitrate, Deg. C.	Number of Detonators Fired in Charge	Result	Compression of Lead Block, Inches
21	8	No detonation	None
50	5	No detonation	None
50	6	Partial detonation	None
70	5	Partial detonation	None
92.5	1	No detonation	None
92.5	2	No detonation	None
92.5	3	Detonation	5/16

Propagation of Detonation in Ammonium Nitrate

For these experiments use was made in each case of a wooden trough, approximately 5½ in. square in cross-section and 10 ft. long, which rested on the ground. Such a trough held approximately 125 lb. of ammonium nitrate. Use was made of both warm nitrate having a purity of 99.64 per cent, moisture content 0.05 per cent and a temperature of 52 deg. C., and of cold nitrate having a purity of 99.19 per cent, moisture content 0.02 per cent and temperature of 21 deg. C. The warm nitrate was made use of to insure detonation and was placed at the initiating end of the train. The effect was determined by the size and extent of the crater produced beneath the box.

Test 1. The box was filled for a distance of 3 ft. with warm ammonium nitrate and the remainder with cold nitrate. Eight special tetryl electric detonators were imbedded in the warm nitrate and shot, but the caps only fired and there was no explosion of the nitrate.

Test 2. The above loading conditions were duplicated except that in place of the tetryl detonators a stick of blasting gelatine was used as the primer. A complete detonation of the ammonium nitrate resulted, giving a crater 11 in. deep x 6 ft. 6 in. wide at the initiating end and 7 in. deep × 5 ft. wide at the opposite end. The total length of the crater was 13 ft.

Test 3. In this case the box was completely filled with warm ammonium nitrate and primed with two sticks of blasting gelatine. The crater was practically the same as in test 2—i.e., 10 in. deep x 6 ft. 6 in. wide and 7 in. deep x 5½ ft. wide and 13 ft. long; the chief difference being in the width of the far end of the crater, which may have been due to a higher order of detonation caused by the increased priming charge.

Test 4. Warm ammonium nitrate only was used in this test. In the center of the box, and for a distance of 2 ft., a layer of nitrate 1 in. deep x 5½ in. wide was maintained. From each end of this 2-ft. length ammonium nitrate was sloped up flush with the ends of the 10-ft. box. A stick of blasting gelatine was placed at one end and on firing, the first half of the ammonium nitrate train detonated, but the wave failed to propagate through the 2-ft. length of powder which was but 1 in. deep. The crater was 8 in. deep, 3½ ft. wide and approximately 4½ ft. long.

In general the results show that ammonium nitrate *per se* will propagate its own wave of detonation, but the force gradually falls off, as shown by the decrease in depth and width of the crater at the end opposite the priming charge. Test 4 also shows that the explosion

wave failed to travel through a 1-in. layer of ammonium nitrate.

Present Conclusions and Plans for Future Investigations

Some of the tests described above and many other tests by fire were observed by Mr. Schoen, and they are described by him in a well-illustrated report.[18] He concludes "that ammonium nitrate offers very much the same fire hazard as sodium nitrate—that is, an indirect hazard through the liberation of oxygen at moderately high temperatures, which gas serves to intensify combustion and tends to increase the extent and spread of fire"—in which conclusion I concur.

There is need for a decision on the explosion hazard also and I believe from all the evidence thus far at hand we are justified in holding that ammonium nitrate when stored by itself in wooden receptacles and apart from explosive substances is, for transportation and storage, not an explosive.

There still remains much to learn as to the behavior of ammonium nitrate, especially when associated with other ammonium compounds, as at Oppau, and this topic will be made the subject of investigation by a special committee appointed by the National Research Council consisting of Charles P. Beistle, Bureau of Explosives, A.R.A.; C. A. Bigelow, Institute of Makers of Explosives; S. P. Howell, Bureau of Mines; Charles E. Munroe, National Research Council; C. G. Storm, Ordnance Department, U. S. A.; R. C. Tolman, Fixed Nitrogen Research Laboratory, and a representative of the Bureau of Ordnance, U. S. N., to be named later.

Negligence in Explosion Cases Construed

In the consolidated cases of the Republic of France, the King of Great Britain and Ireland and the Aetna Explosives Co. against the Lehigh Valley Railway Co., the Supreme Court of New Jersey, the actions involved grew out of the same explosion. (114 Atlantic R., 242.)

Part of the claim of France was for benzene and wet guncotton in railroad cars on the Lehigh Valley dock. For this the jury rendered a verdict for France which was not questioned. But part of the claim of France was for wet guncotton in cars on the Central Railroad dock; part for picric acid, N. C. powder and cannon powder in cars in the barge Rockwell; and on these the verdict was against France, which appealed.

The claim of the King of Great Britain was for smokeless powder on barges, that of the Aetna Explosives Co. was for powder on a barge; the verdict was against these claimants, who appealed.

It was urged that if the jury was right in finding in favor of France for the benzene and wet guncotton on the Lehigh Valley dock, it must logically have found negligence with reference to the guncotton on the Central Railroad dock. But the court said this argument overlooks the fact that there was an element of negligence as to these explosives that was not present in the case of the other explosives belonging to France. One of the causes of negligence alleged was the failure to provide adequate facilities and proper measures for removing and isolating cars which caught fire and cars loaded with dangerous explosives likely to explode in or near which fire might be discovered. And it might properly be found that there was no negligence on the part of the Lehigh Valley Railroad Co., so far as concerned the starting of the fire, and yet quite properly found that there was negligence after the fire started in removing or isolating cars on its dock. This theory of liability is not applicable to cars standing on the Central Railroad dock with which the Lehigh Valley had nothing to do, said the court, and the verdict against France was upheld.

The question of liability in the cases of Great Britain and the Aetna Explosives Co. was more difficult. It appears that the claimants' stocks of supplies were on barges which had, without right and apparently without knowledge of the railroad company, been tied up to the Lehigh Valley wharf, one barge to another, and after the fire started had cut loose and were being towed away. The court held that persons who tied their barges to other barges tied up to the wharf of another were guilty of trespass on the rights of the wharf owner. And he could properly assume, in the absence of notice to the contrary, that owners of barges loaded with dangerous explosives would not tie their barges to barges tied at the wharf and loaded with dangerous explosives in violation of harbor regulations, and hence was under no duty to them, and they were not entitled to recover damages for an explosion where a fire started at the wharf.

Orders by Commission Merchants for Foreign Corporations

A case of interest to foreign corporations contemplating the doing of or doing business in the State of New York comes from the Appellate Division of the New York Supreme Court (197 App. Div., 788). Action was brought by the Eagle Manufacturing Co., Inc., against Arkell & Douglas, Inc., for goods sold. One of the defenses to the action for the purchase price of the goods was that the plaintiff was doing business in New York in violation of the general corporation law.

The orders were taken by Malone & Nicholson, who were engaged on their own account in business as brokers or commission merchants in New York City. They represented a number of foreign corporations having factories, including the plaintiff. The lease of the premises occupied by the brokers was in their own name, as was also the telephone contract. The manufacturing firm had nothing to do with the running of this New York office or its expenses, and contributed nothing toward its maintenance. The only goods of the factory in the possession of the brokers were samples. The goods sold never passed through the broker's hands.

Further, the plaintiff never had any stock of merchandise in the State of New York, nor did it have any bank account or any offices there, nor did it keep any books in the state. The goods involved in the suit were sold f.o.b. factory in West Virginia.

By a vote of 3 to 2 the court held that this state of facts established as a matter of law that the plaintiff was not doing business in the State of New York as contemplated by statute, so that non-compliance with section 15 of the corporation law would prevent actions on contracts based on the brokers' orders.

X-Ray Data on Martensite Formed Spontaneously From Austenite

Coarse-Grained Austenite, After Fifteen Months at Room Temperature, Is Found Unchanged in General Appearance, but Has Become Very Hard and Magnetic—Its Present X-Ray Spectrogram Is That Characteristic of Very Fine-Grained Ferrite

By EDGAR C. BAIN

HULL'S METHOD of crystal analysis,[1] although usually applied to very fine-grained metal or powders, affords data for estimating grain size over quite a range. In general it could not compete with an actual grain count under a microscope, but several orders of grain size can be recognized quite definitely by the appearance of the bands of the film pattern. Furthermore, as we shall see, it is useful for grain study where the microscope fails entirely. The Hull method and its minor modifications have been amply described from time to time, but it may be fitting to consider how these grain size data are obtained.

X-Rays for Estimating Grain Size

If a single crystal is mounted in a monochromatic beam of X-rays after the fashion of the early workers,[2] a definite number of positions with respect to the beam will be found which will partly deflect the beam. In these positions a diffraction image of the source is projected in some direction. Assume the crystal to be in a position to produce an interference maximum and then rotate it with the beam as axis, and a conical path will be traced by the deflected beam. A single grain placed at random has small chance of being in a position to "reflect" the beam at all. Its chances depend upon the number of possible plane spacings in the crystal which exceed one-half the wave-length and upon the divergence of the beam. If we increase the number of differently oriented crystals in the beam, we proportionally improve the chances for some diffraction image to be projected. Only a limited photosensitive surface is ordinarily provided to record these deflections of the beam, and if the area is small, it again lessens the number of reflections recorded. As an example, there are usually about five diffraction images recorded on the author's films from the mounted specimen whose grains are 1 sq.mm. in cross-section on the average.[3] Such a dashed spectrogram is Fig. 8.

FIG. 1—ORIGINAL AUSTENITE. × 100. ETCHED WITH HNO_3

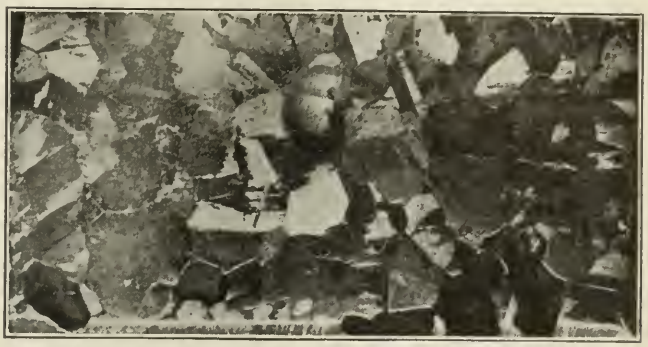

FIG. 2—ORIGINAL AUSTENITE, × 4½. OBLIQUE ILLUMINATION. ETCHED WITH HNO_3

When there are sufficiently numerous grains or crystal fragments in the beam, the number of tiny images from similar orientations is so great that they overlap on the film and produce a smooth, evenly dark band. The largest grain size which can give this sort of band is of course the optimum for crystal study. This situation represents one general order of grain size and is easily recognized.

It may perhaps be of interest to note that as we refine the grain size still further we reach a condition at which the bands widen and lose contrast. This condition is realized very seldom indeed in metals, but doubtless crystalline fragments of colloidal size would yield such patterns. In general to keep the diffraction band from spreading over one degree in width the crystalline metallic fragments should have all gradations in size from 75 to 150 atom rows. To sum up then, with the very coarse structures we have only dashes on the

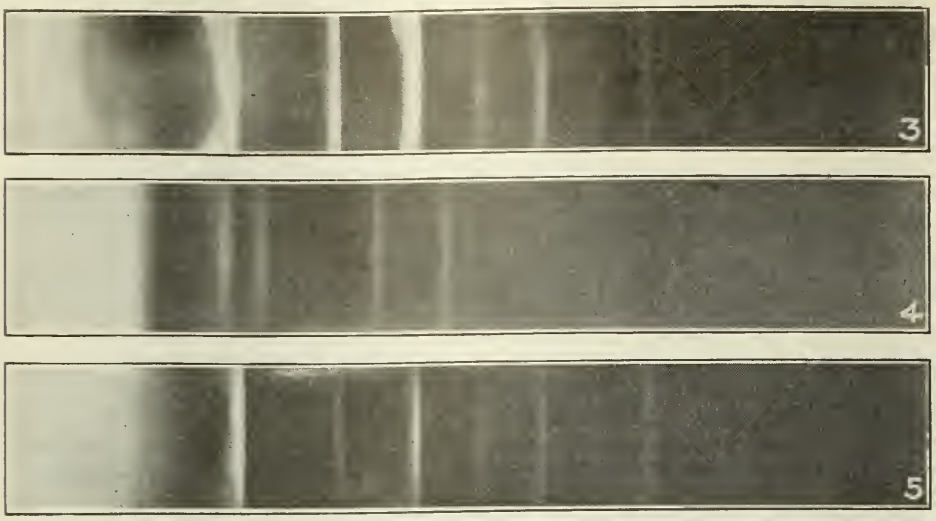
[3] E. C. Bain and Zay Jeffries, "Mixed Orientation Developed in Crystals of Ductile Metals by Plastic Deformation," CHEM. & MET. ENG., Oct. 26, 1921, p. 776. In this paper the use of the X-ray spectrometer for following grain size change is described.



FIGS. 3 TO 5

Fig. 3 — Spectrogram of austenite after transformation to martensite.

Fig. 4 — Spectrogram of austenite. Ordinary grain size.

Fig. 5 — Spectrogram of pure ferrite, fine grain.

film which gradually become smaller with grain refinement until narrow continuous bands are produced. With further reduction in crystal size we gradually widen the smooth band.

According to the slip-interference theory advanced by Jeffries and Archer,[4] martensite is necessarily a fine-grained material. Regardless of the apparent grain size of the material, which is in reality the grain size of the parent austenite, it probably derives its hardness from the resistance to slip which very fine crystal fragments offer. Of course, the useful martensite of good practice is extremely fine-grained even as to microscopic appearance, being transformed from a fine-grained austenite. But if it could be shown that specially prepared martensite from coarse-grained austenite was also fine-grained, the theory would be enormously strengthened. The data offered below point conclusively to this situation.

It so happens that the specimens which exhibit such definite information on the state of aggregation of martensite also present the rarely noted spontaneous production of martensite from austenite at ordinary temperatures. The analysis of the steel employed for these studies is as follows:

	Per Cent
Carbon	0.32
Manganese	0.57
Phosphorus	0.031
Sulphur	0.013
Silicon	0.13
Nickel	2.81
Chromium	0.06

The specimens were produced by Prof. Chas. Y. Clayton of the School of Mines, University of Missouri, who supplied the analysis.

During the fall of 1921 the author received from Prof. Clayton some steel, presumably extremely coarse austenite, which had been prepared, examined and photographed in the early summer of 1920. Fig. 1 is the micrograph of the austenite at 100 diameters with vertical illumination and Fig. 2 is the same specimen at 4½ diameters with oblique illumination, both made at that time. The characteristic twinned crystals of quenched austenite are in evidence.

When placed in the X-ray spectrometer, the original polished and etched surface was in such perfect condition that no alteration was detected by a small pocket glass, but the author was astounded to find a normal spectrogram of ferrite, Fig. 3. Compare this with Fig. 4, the spectrogram of pure austenite in a fine-grained specimen. A test with the magnet gave no doubt that the supposed austenite was very largely transformed.

[4] Zay Jeffries and R. S. Archer, "The Slip Interference Theory of the Hardening of Metals," CHEM. & MET. ENG., June 15, 1921, p. 1065.

For further comparison, Fig. 5 shows the spectrogram of a very fine powder of pure iron (ferrite).

Obviously the period of 15 months had been sufficient to convert the austenite to martensite at ordinary temperatures. Fig. 6 shows the same area as photographed in Fig. 2 after the transformation had taken place. At this magnification the macrostructures may be said to be identical.

Gradual change of austenite to martensite at ordinary temperatures has been observed by Honda and Idei.[5]

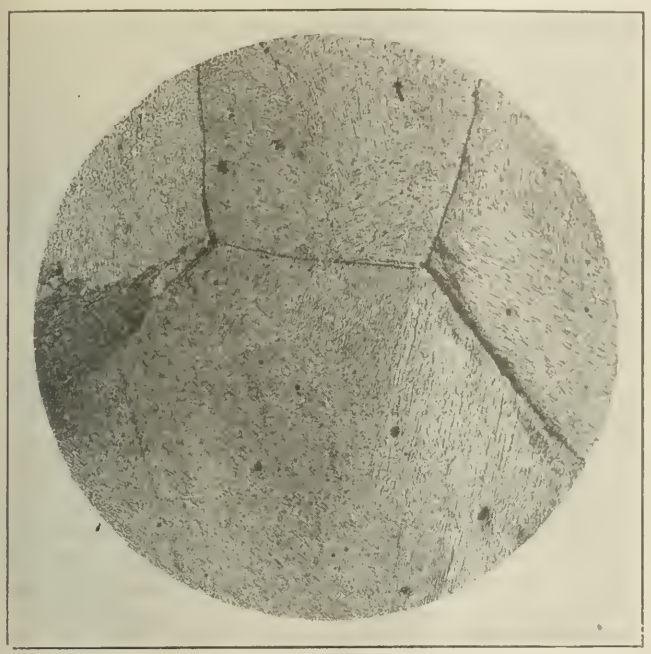

FIG. 10—MARTENSITE FROM SPECIMEN USED FOR SPECTROGRAM IN FIG. 3. × 100. ETCHED WITH PICRIC ACID

They measured the progress of the transformation by the increase in hardness as time elapsed. However, the starting material in that case was a mixture of austenite and martensite, while the material studied here was undoubtedly entirely austenite. The hardness history of these specimens is not at hand, but the changed material is 555 Brinell as against 652 for martensite of the same steel prepared as such at the same time as these specimens were treated to produce austenite.

Fine-Grained Despite Appearances

But the data show more than the spontaneous transformation. Fig. 7 is a photograph at 7½ diameters of a small ingot of coarse tungsten. It is obviously of somewhat finer grain size than the original austenite preserved in the martensite. Yet its spectrogram is the characteristic dashed one described above and shown in Fig. 8.[6] *The film of the martensite is not at all characteristic of such coarse-grained material, though derived from an apparent grain size which was larger.* The microscope here has proved misleading for true grain-size determination.

However, there is an interesting appearance in a deeply etched area of the martensite at 100 diameters. Fig. 10 is a micrograph of the same area which had been exposed to the X-rays. Within the original well-marked grains there appear very plainly discontinuities of etching figures. While these configurations could scarcely represent the new grain size of martensite, they do show that the region within the grain is a complex. On the other hand, the transformation, taking place at ordinary temperature, was probably very slow and might therefore give rather large areas of crystalline continuity. Perhaps in this one detail it is not representative martensite.

[5]Kotaro Honda and Sakae Idei, "On the Distribution of Hardness in Quenched Carbon Steels, and Quenching Cracks." *Science Reports*, Tohoku Imperial University, First Series, vol. 4, No. 6, December, 1920.

[6]Fig. 9 represents the spectrogram for fine-grained tungsten.

Summary

To summarize, we find in martensite an apparent grain size somewhat larger than that of a truly coarse-grained tungsten ingot which yields a pattern characteristic of a very fine-grained metal. The old grain boundaries do not inclose single orientations, but many crystal fragments which result from the allotropic transformation of the gamma iron arrangement to the alpha iron arrangement. This fact corroborates very conclusively the theory of the fine-grained nature of martensite.

Cleveland, Ohio.

German Substitutes for Ferromanganese

Efforts of the Germans to procure high-grade manganese ore from foreign countries during the war had very little success. The main sources of supply before the war were Russia (from which nearly 400,000 tons was imported in 1913), British India, Spain and Brazil. All those supplies stopped at the beginning of the war. Small quantities of manganese ore were then imported from Sweden, but this was entirely insufficient.

For this reason steel production was dependent almost entirely upon reserves of manganese already accumulated in the country. Greatest economy was required, and for this reason the available foreign ore was mixed with German ore. Increased production of the latter was taken energetically in hand. The main deposit to draw from was the hematite of the Lahn Valley, but even the iron ore in the Sieg district, containing a small percentage of manganese, was largely used by steel works.

Apart from this, ferromanganese was made from the so-called Siegerland slag, from blast furnaces smelting Sieg ore, a slag containing from 8 to 9 per cent of manganese. Vast supplies of this cinder, sufficient for many years, were available. This ferromanganese was called "Siegerland chip steel," and was produced by the blast furnaces being burdened with two-fifths Siegerland slag and three-fifths iron scrap or turnings. Slag obtained at the Austrian Steel Works in Donawitz was even better for such purposes.

All efforts to find a substitute for manganese for the deoxidation of steel proved futile. The industry so far succeeded, however, in adapting the deoxidation process to low-grade spiegels and ferros that they were able to produce satisfactory results with the means at their disposal. Good results were obtained by using the deoxidation agent in liquid state. It should be mentioned that ferro-aluminum, containing from 15 to 20 per cent aluminum, was used during the war for a deoxidizer.

Since the war the importation of manganese ore has again been resumed, but the main sources of pre-war supply are not drawn upon, Sweden and Spain now furnishing most of the tonnage. These imports are in no way equal to the pre-war imports, no doubt due to the considerably reduced steel production, but also to the fact that the experience gained during the war has made Germany's steel industry less dependent upon foreign manganese ore.

The Problems of the American Shale-Oil Industry

An Outline Intended to Show Briefly the Present State of Our Knowledge in Various Divisions of the Field of Oil-Shale Technology and to Suggest Some Channels Which Future Investigational Effort May Take

By CHARLES L. JONES

Industrial Fellow of the Mellon Institute of Industrial Research, University of Pittsburgh, Pittsburgh, Pa.

THE one fundamental problem of the shale-oil industry may be stated in a sentence: it must make money from oil-shale. Expressed more specifically, it must afford products, and especially staple products of value to civilization, at the lowest possible cost. Its object is not to produce oil from shale with high thermal efficiency, high recovery of saturated oils, or under ideal conditions in any other respect, except in so far as this can be done in such a way as to supply commercial demand at low cost. The real problem, then, is to obtain all necessary fundamental information on our American oil-shales by systematic research; to develop industrial-scale apparatus which is suited to deal with these shales, simple and economical in operation, and based on sound scientific principles; to refine the crude oil thus obtained into staple products for which there is a ready market; to develop markets for such products of the industry as cannot find an advantageous sale under present conditions; and so to organize the various processes involved that oil-shale may be turned into profit.

Oil-Shale an Indefinite Term

It should be emphasized strongly at the start that "oil-shale" is a term which is even more indefinite than petroleum. Certain shales, for example those of New Brunswick, yield crude oils of relatively non-paraffinaceous mixed base, whose nature is such that their refining may not be effected economically with recovery of any other products than motor fuels and fuel oil, while, on the other hand, crude oils containing large percentages of paraffine may be obtained from such shales as that at Elko, Nev., and offer refining possibilities of an entirely different nature. In fact, it may be said that the most outstanding characteristic of oil-shales is their variability. Obviously, oil-shales may be classified as above on the basis of their destructive distillation products. It has also been suggested by W. A. Hamor that a more logical classification might be made on the basis of the predominating hydrocarbon minerals associated with various oil-shales whose distillation products are generally similar to those from the accompanying oil-shales. For example, Arcadian shale might be classified as albertitic; Australian, coorongitic; Kentucky, grahamitic; Scottish, torbanitic; and Colorado, gilsonitic.

When it is considered that it is possible to produce a considerable variation in the crude oil from any one of these oil-shales by varying the conditions of retorting, it is seen at once that a complete solution, if possible, of the problems of producing finished products from a given shale will by no means represent any solution of the problems of the American shale-oil industry. The folly of reasoning from one oil-shale to another by analogy has been demonstrated; perhaps never more clearly than in the case of the Commonwealth Oil Corporation, formerly operating in New South Wales. Complete Scotch retorts were installed in this case, without proper preliminary experiment, and soon had to be abandoned because of their inapplicability.

Growth of Oil-Shale Industry Likely to Parallel That of the Petroleum Industry

The fundamental ignorance of the properties of shale-oils produced from various American shales under different conditions, the uncertainty with regard to many questions as to the origin and nature of the shales themselves, and the dearth of scientific information respecting the hydrocarbons and oxygen, sulphur, and nitrogen compounds present make it seem probable that the primary development of the shale-oil industry in many ways will parallel the early growth of the petroleum industry, in that cut-and-try methods will be more in evidence than the intelligent application of scientific principles. A scientific principle must be established before it can be applied. However, the technical man will be more conspicuous than in the early petroleum industry, both because the processes involved in recovering and refining shale-oils are more complicated than those encountered in petroleum work, and because the shale-oil producer must face a market which, while not knowing exactly what it wants in all cases, nevertheless is educated beyond the wildest dreams of the early petroleum pioneers. Both these factors must influence profoundly the methods of attack upon the problems of the industry. It is interesting to note that, in 1860, the problem confronting the petroleum industry was to educate a public accustomed to lamp oil from crude coal-oil to the use of kerosene from petroleum, while the situation faced by the prospective shale-oil producer in many ways is practically the reverse of this.

Other Petroleum Substitutes Which May Compete With Shale-Oil Products

It is difficult to consider the problems of the shale-oil industry without at the same time taking into account the problems involved in the development of substitutes for petroleum and its products from other sources, such as the low-temperature distillation of coal, lignite, peat and miscellaneous organic materials. The effect of these products on the industry will be to limit the prices to which shale-oil products can rise after competition from natural petroleum has been eliminated by exhaustion of supply. However, the production of these low-temperature tars need not hinder the development of a shale-oil industry, inasmuch as the field is large

enough to accommodate all possible substitutes for petroleum. If there were at the present time a low-temperature carbonization industry of the proportions of the present byproduct coke industry, with a ready-made technology of preparing satisfactory petroleum substitutes economically, such an industry could supply less than 5 per cent of the current national demand for petroleum. To be sure, the byproduct coking industry is expanding rapidly, but this will afford some conception of the impossibility of supplying our future needs for petroleum by low-temperature carbonization alone. On the other hand, alcohol represents a different type of competing product, in that its production is limited only by price and demand, so that it may reasonably be assumed that ultimately the limiting price for motor fuels will be fixed by the price of alcohol. Again the statement must be qualified by the consideration that, until economic conditions are such that tropical vegetation may be used as a source of raw materials, potential alcohol production from the various available domestic sources, and especially from foodstuffs, is not sufficient to dominate the motor-fuel market. It is not the province of this paper to discuss the influence of these related products on the future of the shale-oil industry; but they are mentioned to direct attention to the facts that the production of oil from shale by destructive distillation is fundamentally an economic compromise, that its problems are economic problems, and that, for their proper solution, some acquaintance with these related fields, and especially the development of much information not yet available in these fields, will be necessary.

No One Solution for All Cases

Further, in solving problems which do come up, it is manifestly impossible that one solution will fit all cases. Not only will local variations in transportation, climate, water supply and demand for products largely influence the methods used in treating various shales, but the inherent variations in the oil-shales themselves are so great that the utmost caution must be exercised in applying proved facts regarding one shale to other shales, or in forming generalizations based on limited evidence.

On the other hand, there are many fundamental problems which can be solved without the expense incidental to repeating research work on a large number of shales. For example, most American shale-oils appear to have certain characteristics in common, such as their relatively high percentage of unsaturated compounds, their objectionable odor, their characteristic oxidation colors, and the presence of nitrogenous alkaloidal tars of high molecular weight. Each of these characteristics suggests certain fundamental problems which can be solved by working on a limited number of shale-oils.

The outline of the problems of the oil-shale industry which follows does not aim to deal further with the details of many of the economic problems which must arise; but it is intended to show very briefly the present state of our knowledge in various divisions of the field of oil-shale technology and to suggest some channels which future investigational effort may take, both in the development of commercial processes and in the collecting of fundamental scientific information. It is intended to be suggestive rather than inclusive in its scope.

The material listed has been divided logically into (1) problems for pure-science research and (2) technological problems to be met.

I. Problems for Pure-Science Research

A. The Study of the Nature of Kerogen

1. Morphology, Microscopy and Physical Characteristics

These subjects belong rather to the field of the geologist and petrographer than to that of the chemist. However, the study of the nature of the material from which the kerogen originated and of its various forms must precede definite chemical study; it will also suggest the most profitable lines of attack from a purely chemical standpoint. The field has by no means been exhausted, but work now being done along these lines by Dr. Reinhardt Thiessen,[1] of the United States Bureau of Mines, should add much to our knowledge of American shales.

2. The Chemical Nature of Kerogen

(*a*) Separation of kerogen from inorganic material.

(1) By flotation. This has been attempted at the Mellon Institute, but without much success. Starting with a material containing 65.8 per cent ash, a concentrate containing 61.25 per cent and tailings containing 68.68 per cent ash were obtained in a Callow cell, using a small amount of pine oil as the flotative agent. While it is possible that different conditions may effect greater concentration, it is not probable that ash-free kerogen can be prepared in this manner.

(2) By gravity separation.

(3) By the Trent process.[2] This has been attempted by the U. S. Bureau of Mines, with results very similar to those obtained in the case of flotation.[3]

(4) By heating oil-shale under high-pressures, with the idea of using pressures sufficiently high to retard the formation of oil vapors, which would be accompanied by increase in volume. Negative results were obtained by this method, up to 1,600 lb. per sq.in. pressure.[4]

(5) By the action of solvents on the kerogen. No known solvent seems capable of effecting such a separation; hence the action of solvents is included below under the chemical study of kerogen, rather than under its separation from ash.

(6) By the action of solvents on the ash. Numerous attempts have been made by various investigators to dissolve the ash from finely divided shale by means of acids, with only partial success. Alternate treatments with hydrofluoric acid and aqua regia seem to be most effective, but even these are not capable of reducing the ash content to zero, and the kerogen seems to be considerably altered by the chlorinating and oxidizing action of the aqua regia. Hydrofluoric and hydrochloric acids, alternately used, do not change the kerogen so much.

(*b*) The study of the chemical nature of kerogen as shown by its reactions. In general, it may be said that the investigations of the chemical constitution of coal could be repeated profitably on oil-shale, if its chemical nature is to be elucidated and its exact relation to coal fixed definitely. As a guide for this work,

[1] See, for example, *Bull. Geol. Soc. Am.*, vol. 32 (1921), pp. 72-3; or *Econ. Geol.*, vol. 16 (1921), pp. 289-300.

[2] On the Trent process, see Bacon and Hamor, "American Fuels," vol. 1, McGraw-Hill Co., 1922.

[3] Private communication.

[4] Unpublished work, Mellon Institute of Industrial Research.

the review of the literature on the constitution of coal prepared by Wheeler and Stopes[5] is valuable, while the later work of the Kaiser-Wilhelm Institut für Kohlenforschung[6] is suggestive in many cases. Some lines of purely scientific research which should be covered are indicated as follows:

(1) Ozone has been used to produce considerable percentages of water-soluble materials from coal, but its action on oil-shale has never been studied.[7]

(2) Studies of the solvent action of the following and other solvents should be extended to cover a larger number of shales. Especially should uniform conditions of extraction be established, and the properties of the products obtained reported in terms which would permit some comparison of the work of different investigators.[8]

(*a*) Pyridine,
(*b*) Aniline,
(*c*) Phenol,
(*d*) Liquid sulphur dioxide,[9] and
(*e*) Liquid ammonia, suggested by the presence in oil-shales of complex nitrogen compounds which reasonably could be expected to be soluble in it.

The solvent action of the ordinary bitumen solvents is so slight as to offer little promise of yielding any significant results; but extractions at relatively high temperatures and pressures with benzene, carbon bisulphide, chloroform and carbon tetrachloride might give interesting products. In this connection a study from a quantitative standpoint of the adsorption of crude shale-oils or extracted bitumen by finely divided clays is needed, for the percentage of material dissolved out of a shale by any of these solvents bears no necessary relation to the percentage of soluble material present, owing to adsorption effects.

(3) Studies should be made of the solvent action of various reagents which react chemically with the kerogen. Some of the solvents listed under (2) may be placed in this class.

(*a*) Selenium oxychloride. Preliminary work has been done with this compound by a number of investigators, but it seems to so alter the kerogen as to offer small hope for any clean-cut results.

(*b*) Sulphuryl chloride is said to be superior to selenium oxychloride in many respects, some work having been done with it as well.

(*c*) Acetylation, sulphonation, nitration and chlorination may be carried out on the oil-yielding substance, but so far as is known the products have never been examined. In some cases—e.g., nitration—it is necessary to employ a solvent to extract the products formed.

(*d*) The kerogen forms a dark colored complex with sulphuric acid,[10] at 110-120 deg. C. The study of this product might throw further light on the chemical nature of kerogen.

(*e*) Determination of methoxyl content.[11]

(*c*) The study of the chemical nature of kerogen as revealed by ultimate analyses. Very few ultimate analyses are now available on oil-shales from various parts of the United States.[12] If the importance of the ultimate composition of kerogen in its influence on the quality of oil formed were established, an incentive would be provided for obtaining other information of interest. The oil-shale laboratory of the U. S. Bureau of Mines is now studying the ultimate composition of oil-shales.

(*d*) The hydrolysis of kerogen. In many shales the exines of lycopodiaceous spores are quite numerous, and the microscopic evidence on this point seems good, but it is not so well established chemically. Steuart,[13] who made an "artificial shale" from lycopodium spores and fullers earth, obtained crude oil from it very like Scotch shale-oil in gravity and setting point. Evidence of the presence of fatty acids in oil-shale or their production from it by hydrolysis would be more nearly conclusive.[14]

Thermal Decomposition of Kerogen

(*e*) The thermal decomposition of kerogen. The work of Jones and Wheeler[15] on the distillation of coal in vacuo should be carried out on oil-shales. This would involve slow distillation at a pressure of, say, 20 mm., raising the temperature in 50 deg. steps, each step to last long enough for equilibrium to be established. Of course fractions should be separately examined.

The results to be obtained should include the following for each step:

(1) A complete gas analysis, including the determination of olefines heavier than ethylene, and fixing the temperature limits of the evolution of each constituent of the gas.

(2) An examination of the aqueous distillate for ammonia, pyridine and higher bases, and especially for other water-soluble compounds. It has been noted that when oil-shale is distilled at atmospheric pressure, foul-smelling sulphur compounds distill over with the aqueous distillate considerably below the temperature of first oil formation. The suggestion is obvious that some of the compounds responsible for the offensive odor of shale oils are produced by the destructive distillation of a material in the shale distinct from the oil-yielding material. However, practically nothing is known of these changes.

(3) The distribution of nitrogen among the water, the oil and the gas.

(4) The examination of the oil to determine the important physical constants, ultimate composition and constituents soluble in alkali and in dilute acid.

B. Fundamental Research on the Hydrocarbons, Oxygen, Nitrogen and Sulphur Compounds Present in Shale-Oils

This section of the problems of the industry is related so closely to the needs of the petroleum and coal-tar industries along the same line that only a few questions, more or less peculiar to shale-oils, will be taken up. Some idea of the lack of information on the great majority of the compounds present in mineral

oils may be gleaned from numerous contributions to the literature.[16] The case for further research on non-benzenoid hydrocarbons has been stated by Brooks.[17] Scientific inquiry along these lines would be of direct assistance to the shale-oil industry.

Among the subjects of pure-science research of especial interest in connection with shale-oils are the following:

(1) All shale oils appear to contain nitrogenous tars of high molecular weight. The particular interest attached to them lies in the fact that they comprise a large part of the relatively large loss suffered in refining shale-oils, and may constitute as much as one-fourth part by weight of the oily distillate.[18]

While it is believed that the various series of nitrogen compounds may extend from their simplest members through heavier tars to solid compounds stable at high temperatures,[19] little is known of any but the lowest members.

It is possible to hydrolyze tars obtained from some shale-oils, with the production of simpler nitrogen bases, and it seems quite probable that a better knowledge of some of the higher nitrogenous compounds may suggest a commercially feasible process of cracking or treating them to produce non-nitrogenous oils, or at least products of value. As is well known, at the present time the Scotch acid-tars, which are made up largely of these nitrogenous compounds, are burned.

Other possibilities are suggested by the fact that some of these tars, as well as the "asphaltenes" separated from crude shale-oils by means of petroleum ether, are quite soluble in 95 per cent ethyl alcohol. This behavior suggests a fundamental point of difference from petroleum asphalts, which indicates a probable difference in other properties as well.

(2) Many shale-oils, and perhaps all, yield light distillates which rapidly oxidize in sunlight to a wine color. The nature of this coloring material is quite unknown, but research on it may lead to valuable results.

It is suggestive that the material is soluble in dilute ethyl alcohol, is reduced to a colorless compound (leuco base?) by sodium hydrogen sulphite, and is red in acid, but colorless to yellow in alkaline solutions.

(3) The closer study of the gum-forming materials in shale-oil gasolines from a purely scientific viewpoint, and the establishment of the relationships between these and similar compounds in pressure distillates from petroleum should be attempted. The work of Steuart[20] will furnish a starting point.

II. Technological Problems

A. Mining Problems

Our present knowledge of the mining of oil-shale is restricted to the Scotch oil-shale industry. Many favorable factors make it appear that the mining of oil-shale will present no insurmountable problems, but, as in any industry whose profits depend upon tonnage, a big field is open to the engineer's skill in lowering costs by efficient handling of materials.

B. Crude-Oil Works Problems

In the crude-oil works also, methods of handling materials will play an important part. However, the fundamental problems are two: What retort shall be used? And under what conditions shall it be operated?

A number of variously designed retorts have been operated in Scotland and elsewhere. While it is not the function of this paper to discuss their development through the periods when burning oils, paraffine and later ammonium sulphate were the principal desiderata, it should be emphasized that a thorough study of these retorts is a necessary preliminary to any proper consideration of the problems before the American shale oil industry.

During the past five years there has been an almost continuous flow of designs for oil-shale retorts into the U. S. Patent Office. These applications include many permutations and combinations of various simple elements, most of which are by no means novel, but many possible arrangements have been overlooked. Owing to this fortuitous circumstance, it is still possible to invent an oil-shale retorting process, and the enthusiasm of prospective inventors should by no means suffer any diminution.

It should be noted, however, that the success or failure of the considerable number of processes which seem to be designed upon sound principles will be based not upon the sublime inspiration embodied in the patent specifications so much as upon the intelligence with which mechanical difficulties are overcome, and upon the care and technical skill shown in determining and regulating conditions of operation. It is probable that at least a half-dozen of the processes proposed to date are fundamentally sound enough to survive competition if applied to retorting a shale under conditions to which they are suited, and if they are developed intelligently to the point where continuous and economical operation can be obtained.

In accordance with this view, the effort has been made to list only problems which appear to be fundamental. For example, if a certain oil-shale seems to require stirring in thin layers, it may make small difference whether it be stirred in A's agitated retort or in B's, provided that the mechanical efficiencies and operating advantages of the various agitating devices are the same, and assuming good engineering.

1. Retorting Problems

(*a*) What is the best practice in crushing oil-shale before retorting?

It is impossible to present this problem as a general one, as the optimum size of particles depends to a large extent upon the retort which is to be used. In Scotch practice fines are undesirable, while in many of the proposed retorts which contemplate stirring the shale in thin layers and putting it through in very short periods, fine grinding may be essential.

A series of experiments, in which oil-shale particles of various sizes were plunged into a lead bath at constant temperature, indicated that crushing finer than about ¼ in. caused no more rapid evolution of vapor.[21] The whole problem needs closer consideration and determination in a way that will define the physical factors involved independently of any particular retort.

(*b*) Shall steam be used? If so, shall steaming be practiced in the same retort in which oil is produced,

[16] See, for example, Gurwitsch, "Wissenschaftliche Grundlagen der Erdölarbeitung," pp. 1 *seq.*

[17] Chem. & Met. Eng., vol. 22 (1920), pp. 933-7.

[18] Beilby, *J. Soc. Chem. Ind.*, vol. 3 (1884), p. 216.

[19] Beilby, *ibid.*

[21] Unpublished work. The shale in these experiments was not stirred.

or shall the residue from retorting be treated in a separate chamber?

The answers to these questions must vary with the retort which is used. The Scotch retort in its present form operated without the use of steam would be an absurdity, while it is possible to design a retort which will produce just as good oils without the use of steam as with it.[22] Granting, then, freedom of choice in retort design, it would seem that the use or non-use of steam depends upon the cost of steam under the given conditions, the increased yield of ammonia obtained, and the difference in retorting cost caused by its use. The latter would require analysis for each new case, and would include difference in capital cost and operating cost on retorts, plus the additional expense caused by manufacturing a relatively large volume of water-gas, which must be handled, stored and burned, in place of burning the gas-forming constituents directly out of the spent shale. The determination of the magnitude of these various factors for different shales presents a large field for research.

The present state of our knowledge on the effect of steam and gases in ammonia recovery has been summarized by Franks.[23]

Rate of Heating

(*c*) What is the proper rate of heating to employ? Is oil that is produced in a retorting time of 30 minutes or less as good as oil that is produced in 3 or 4 hours or more?

This problem has received some attention, and many conflicting opinions may be found in the literature, but the issues in connection with it have not been differentiated clearly. Objections offered to short retorting periods usually are based on inferiority in experimental short-time oil, due to the fact that it has been necessary, as a consequence of the design of the experimental retort, to employ high temperatures in order to secure short retorting times.

Again, the quality of the oil obtained depends upon time, temperature and pressure during its sojourn in the retort, so that an oil made in 3 hours with the use of large amounts of steam or gases to remove oil vapors from the retort may represent the same actual contact time at the retort temperature for the oil itself as a similar oil made without steam in about one-sixth the time.

These conditions are not always easy to determine; but it should be possible to settle this controversy satisfactorily by small-scale experiment, provided care is taken to define completely vapor contact times, refluxing effects and actual wall temperatures, as well as the retorting time. A simple comparison of oils made with short and long retorting times means absolutely nothing without these other data.

Influence of Secondary Decomposition

(*d*) What is the influence of secondary decomposition? What is the maximum permissible temperature along the walls of a retort, and what is the effect of the time factor in this connection?

It has been accepted generally as axiomatic that the maximum yield of good oil is obtained by withdrawing all vapors as soon as possible without heating them above the temperatures at which they are formed. There is a basis for this belief, but it is a half-truth.

By secondary decomposition is ordinarily meant avoidable cracking, which reduces the oil yield below the maximum obtainable. The exact point where primary pyrolysis of kerogen to form oil ceases and secondary decomposition begins never has been defined, but it might be well to accept the yield and quality of oil obtainable from a given shale under optimum conditions in a laboratory retort as the criterion, and assume that any reduction of this yield, due to overheating of vapors, is a measure of secondary decomposition.

Secondary decomposition, in this sense, is a chemical reaction and cannot be defined fully in terms of temperature. It must depend upon time, pressure and the presence or absence of catalysts as well.

It has been shown at the Mellon Institute that shale-oil vapors may be heated as much as 250 deg. C. above the temperatures at which they are formed, for short contact times of the order of 1 second, without suffering any marked change in yield, gravity or unsaturation. On the other hand, it is known that much milder overheating for longer periods of time decreases the yield; while, if samples of shale-oil are maintained at or even below the temperatures at which they were formed, in stills provided with refluxing condensers, they may be cracked to coke and gas within several hours.

It may never be possible to treat the reactions involved with the mathematical nicety of simpler ones; but a broad field for research is open, and it may some day be possible to predict the percentage of the theoretical yield which will be obtained in a proposed retort, from a knowledge of its volume, the rate of evolution of vapor, its wall temperature at all points, the magnitude of refluxing effects and the pressure and gas-tightness under given operating conditions.

Temperature at End of Run

(*e*) What is the best "finish" temperature to use in the retort—i.e., how hot should the shale be heated before discharging?

The answer to this question will depend largely on whether steam is to be used or not.[24] If steam is used, "finish" temperatures should be sufficiently high to permit practically complete removal of fixed carbon from the spent shale by the steam, according to the water-gas reaction. The maximum temperature in Scotch practice is about 1,300 deg. F. Where steam is not used, the desirable "finish" temperature depends entirely upon the disposition of the spent shale. If this is to be burned, it would seem to be economical to carry the distillation no further than is required to recover all obtainable oil, since it is cheaper to burn a given amount of gas-forming constituents out of the spent shale than to distill the gas from them, handle it, store it in gas-holders, and then burn it. The spent shale as discharged is already hot and in ideal condition for immediate combustion. It appears that it can be burned easily under the proper conditions, but many problems remain to be considered adequately.

(*f*) What pressure should be used in the retort?

Mechanical limitations must influence the decision as to pressure. If ovens or retorts of ceramic material are used, it will be desirable to operate at very slight positive pressure, in order that the retorts may be self-

[22] See Botkin, CHEM. & MET. ENG., vol. 24 (1921), p. 876; and *U. S. Bureau of Mines Reports of Investigations*, No. 2254. For an exposition of the opposite view, see George, *Colorado Geological Survey Bull.* 25.

[23] CHEM. & MET. ENG., vol. 23 (1920), p. 1149.

[24] The question of the use of steam has been considered in (*b*), pages 549 and 550.

sealing and any unnecessary oxidation of oil vapors may be avoided. Byproduct coke-oven practice is available for guidance in such cases.

On the other hand, where retorts are constructed of iron or alloys, more latitude in pressure may be enjoyed, and it may be desirable to operate under negative pressure, to assist in removing vapors quickly. Retorting under higher pressure yields a larger percentage of saturated oils, as has been reported by George.[25]

While pressure cracking of oil-shale might present problems which could not be solved economically on a commercial scale, the influence of pressure on the character of the oils formed requires attention.

(*g*) What is the influence of the admission of air or combustion gases retaining some oxygen on the quality of the oils formed?

Certain inventors propose to pass the combustion gases through oil-shale, to assist in the retorting process; and while it is known that shale oils are very susceptible to oxidation, the exact effects of small percentages of oxygen in the retort atmosphere do not seem to have been determined. The practice of introducing a small amount of air in the Young and Beilby retort is an argument for the utility of the above procedure.

Influence of Various Added Materials

(*h*) What is the influence of adding various materials to the oil-shale during the retorting process?

The field for any modification of the retorting process such as is suggested by this question would be very limited indeed, in view of the large tonnage of low-grade material which must be handled and the fact that few possible materials are available at low enough cost which might have beneficial effects.

Gypsum has been mixed with shale before retorting, and the effect of the steam produced has been shown to be similar to the effect of the same amount of steam introduced from an external source.[26] Aluminum chloride[27] also has been mixed with shale before retorting; but it was shown that it sublimes into the condenser for the most part before oil is evolved from the shale, later polymerizing the vapors entering the condenser to a solid plug of bituminous material. It also has been proposed to introduce iron or iron salts in the retort to reduce the sulphur content of the oils.[28]

The study of the action of various catalysts and reacting substances should give at least a new insight into the retorting process, if it is not productive of important commercial results.

Choice of Fuel

(*i*) What fuel shall be used? What is the heat balance in the retorting operation?

The question of the sufficiency or insufficiency of fixed gases as retort fuel has been considered most fully by Gavin and Sharp,[29] who have made an excellent start in this field of inquiry.

(1) The results of researches such as the above should be extended to include a larger number of shales. However, much of this horizontal increase in our knowledge of oil-shale must await commercial development on a scale sufficient to pay for research.

(2) The effect of the "finish" temperature on the gas yield has not been considered fully. For example, Gavin and Sharp[29] assume that the amount and calorific value of gas recovered at 482 deg. C. and at 925 deg. C. is the same, although they mention the fact that higher "finish" temperatures produce more gas. A clear distinction must be drawn in this connection between retorting temperatures and "finish" temperatures, since there is no necessary connection between the two.

(3) The heat of reaction involved in the formation of oil from kerogen is a figure essential for striking a proper heat balance, but there is much that is not known about it.

McKee and Lyder[30] have made an impressive beginning in the field by developing a calorimetric method for the direct determination of the heat of reaction. Their results, however, indicate a considerable endothermic reaction, while the investigation of Gavin and Sharp[31] shows a rather strong exothermic reaction. The discrepancy seems to indicate a field for further investigation inasmuch as both pieces of work are quite authentic.

2. Ammonia Recovery Problems

The production of ammonia in the retort has been considered; and inasmuch as the manufacture of sulphate of ammonia *per se* is in effect a separate industry, having its own problems and its own equipment purchasable in the open market, it need not be discussed here. It is pertinent, however, to call attention to the profound influence which ammonia recovery may have on the solution of the retorting problem.

3. The Disposal of Spent Shale

In the majority of cases, spent shale probably will prove to be valueless and will have to be dumped. In particular cases, however, it is entirely possible that the manufacture of byproducts from spent shale may rival the main business of manufacturing shale-oil. Among the possibilities suggested are the following:

(*a*) The recovery of potash.

The spent shale obtained from many shales contains a small percentage of potash, and in some cases this might be leached out at a profit. The problems presented should not be difficult to solve, but have not yet been met.

(*b*) Use direct as a fertilizer.

Used alone, the potash content of spent shale would scarcely be sufficient to class it as a fertilizer. It seems probable, however, that, in certain cases where the shale plants are located in agricultural districts and no freight charges must be met, the spent shale might be sold locally as a filler for compounded fertilizers, and might command a price based on its soluble potash content.

(*c*) Preparation of decolorizing "carbon" from spent shale.

While this field does not seem to offer promise, it must be admitted that its possibilities have not been explored to any extent.

(*d*) Recovery of precious metals.

This "problem" seems to give more trouble to the unwary investor than to the technologist, but "values" have been reported in some oil-shales, and it is not impossible, though unlikely, that in particu-

[31]*Loc. cit.*

lar instances commercial recovery may be carried out.

(*e*) Use as an insulating material.

Schmidt[32] has advocated the use of spent Wurtemburg shale as a heat-insulating material. While such a use might have only local significance in this country, it should receive further consideration, if only as a possible source of insulating brick for use in shale works not near better raw material.

(*f*) Brick manufacture.

Thomas[33] has discussed the use of spent shale in brick manufacture and reports that practical tests have shown that satisfactory brick can be made from spent Colorado shale.

The success of such a plan will depend almost entirely upon the nearness to the market, and it appears that, in the case of our richest Western deposits, the manufacture of any large quantity of heavy low-grade products of this sort will be out of the question. On the other hand, there are shale fields more favorably located where conditions are more promising. Only a very limited number of ash analyses have been made, and a broad field is open for further work.

(*g*) Manufacture of portland cement.

A process of retorting oil-shale has been proposed,[34] in which the spent shale is burned in a rotary cement kiln and in which the retort proper is heated by waste heat from the kiln.

The suggestion that portland cement be made from spent shale apparently has occurred to many, but little actually is known about the suitability of spent shales from various localities. The economic limitation imposed by transportation also seems likely to restrict this use to certain deposits.

4. The Disposal of Excess Gas

No problem is presented in disposing of excess gas, since the communities which must be built up to operate shale works of any size can absorb any excess not used around the works.

It should be pointed out, however, that shale gases made without steam contain considerable percentages of olefines, the amount reaching 10 per cent in some cases. This should be sufficient to warrant the use of the gas as the basis of a chemical products industry at some future time. It is beyond the province of this paper to detail the possibilities, as the olefine-products industry forms a separate field.[35]

C. Refinery Problems

The problems of the petroleum industry[36] are to a large extent also the problems of the shale-oil industry. However, problems such as the disposal of acid sludge take on a new significance where the amount produced exceeds 20 per cent of the volume of crude oil refined.

It will not be attempted here to deal with all the problems of shale-oil refining. Of course, the oil should be refined to recover products of maximum value, and in view of the wide variations among shale-oils, no general or sweeping statements can be made. Many problems can be handled ably by those experienced in petroleum refining.

On the other hand, there are certain fundamental differences between shale-oils and petroleum oils which suggest problems not familiar to the refiner of petroleum. Some of these will be presented.

The most important problem before the prospective shale-oil refiner is the general one of refining a highly unsaturated oil economically. So far as the lighter fractions are concerned, the problem is similar to that of refining pressure distillates, and yet it possesses points of difference from the latter, in that the percentage of unsaturates found in shale-oil gasoline fractions probably averages higher than in the case of pyrolytic gasoline, and in that compounds are present in the light shale-oil distillates which are not found in ordinary pressure distillates.

The problem is met in the Scotch industry by using small quantities of acid and by resorting to several redistillations. The intention of the Scotch refiner is to use as much acid in treatment as is possible without attacking the olefines.[37]

While Scotch practice might be followed on American shale-oils not requiring more drastic desulphurization, it appears that there is excellent chance for improvement in the procedure. The possibility of refining entirely by fullers earth,[38] bauxite, silica gel and various other adsorptive agents has occurred to many. It may be stated confidently that these and all other means of refining which avoid sulphuric acid treatment may look to shale-oils with more hope than to most petroleum refining, not because any proof has been advanced of their superiority, but because the need for some economical method of refining is greater, and because there is more room for improvement in the case of shale-oils. It is possible that the practice of refining oils with sulphuric acid may some day be abandoned.

In case sulphuric acid treatment is adhered to as the basis of the refining treatment, for the lighter fractions other problems must be met. The most important of these is, how far must refining be carried to produce a satisfactory product? Refining loss can be reduced considerably if odor and color are ignored, and a red product is marketed. It is not entirely clear whether such a red color would be an asset or a liability, but we do not yet know to what extent the color is produced by gum-depositing compounds whose presence to any extent in a shale motor-fuel or burning-oil would be objectionable. Refining must certainly be carried far enough to reduce the gummy polymerization or oxidation products within permissible limits. Does this necessitate the removal of the red color or not?

The question of whether lighter acid can be used to advantage has not been dealt with properly. What is the advantage of blending a crude shale-oil with petroleum before refining, if any? Could a cracking distillation be so regulated as to yield a higher percentage of desirable oils in the "once-run oil" from the nitrogenous tars in the crude shale-oil? Could these tars be separated from the oil, and separately treated or cracked to produce more valuable products?

Recovery of Lubricating Oils

Coming to the lubricating oil fractions, and taking into account the variations which may be expected, certain fundamental peculiarities seem again to distinguish these from similar products obtained from petroleum. In general, shale-oils provide a source of only relatively low viscosity lubricants, containing con-

[38] In this connection see U. S. Pat. 1,340,889.

siderable amounts of easily oxidizable material which must be removed.

Even though in the earlier stages of the shale-oil industry in this country no attempt may be made to recover lubricating oils, it must be realized that, although other substitutes may be found for motor fuel, it is probable that oil-shale and coal will be ultimately the only important sources of lubricants, unless some way is found of greatly cheapening vegetable or animal oils. Hence it is important that some means be developed for manufacturing economically as wide a range of lubricants as possible from shale-oils.[39] Means have been found for increasing the viscosity of low temperature coal-tar fractions,[40] which have potential value for this purpose.

Shale-Oil Residues

Another set of problems will accompany the application of shale-oil residues to the common uses for petroleum residues, such as for roofing, paving and compounding with other asphalt products for various purposes. Practice in the Scotch industry has been to carry out a first and partly destructive distillation to coke. This treatment, logical enough in the case of the Scotch shale-oil, the most valuable product of which is paraffine, certainly will not fit all American shale-oils. Not very much is known of the properties of shale-oil asphalts,[41] although from their nature it is to be expected that they will prove intermediate in properties between petroleum residua on the one hand and coal-tar pitches on the other. Studies of air-blowing and sulphurization of shale-oil asphalts do not appear to have been made, but deserve attention. Owing to their nitrogen content, some peculiar properties may be found which will indicate special applications. Mention has been made of the presence in the crude shale-oil of tars soluble in 95 per cent ethyl alcohol.

Minor Byproducts of Shale-Oil Refining

In addition to the staple products mentioned above, a considerable number of specialties may be manufactured from shale-oil; and while these may never assume great commercial importance, they may form the basis of small branches of manufacture under especially favorable circumstances.

On account of their unsaturated nature and accompanying reactivity, shale-oils may possess potentialities not possessed by petroleum as a basis for the chemical manufacture of fatty acids, drying oils and other products. This field is quite untouched, since most of the possibilities of the better-known petroleum industry along this line have not yet unfolded.

Certain shale-oil fractions differ sufficiently in composition from the corresponding petroleum solvents to make it seem reasonable that their characteristic properties may command a market different from or even better than that open to petroleum solvents.

The preparation of various dyestuffs from shale-oils has been advocated by many persons, though mostly by typical promoters of the worst sort. However, it cannot be denied that this field is entirely open, and that it is by no means impossible that a variety of dyestuffs may some day be prepared from shale oils.

The possible preparation of polymerization resins similar to coumarone resins from coal-tar distillates is another field so far unexplored.[42]

Ichthyol,[43] a product manufactured from an Austrian fossiliferous shale, may be prepared from certain American bituminous minerals. However, it commands a relatively small market, and would not repay any great amount of effort.

Judged by present specifications, shale-oils are ill-adapted to furnish impregnating oils for timber. As these specifications are based upon properties desirable in coal-tar impregnating oils, however, it is quite possible that shale-oils should be judged by different standards. Their content of unsaturated hydrocarbons and nitrogen compounds distinguishes them from petroleums and coal tars for this purpose. The Forest Products Laboratory, at Madison, Wis., is obviously fitted to consider the problem.

The application of shale-oils to the froth flotation of low-grade ores has occurred to many workers; but while numercus tests have been made with them, they have not yet been applied commercially with success, to the writer's knowledge. Preliminary tests have not indicated that crude Colorado shale-oils show any marked superiority over crude petroleum under the conditions of experiment. At least one company[44] is said to be marketing shale-oils for flotation, however, and has advertised for sale a trade-marked brand of flotation oil manufactured from oil-shale. It is possible that, with the return of the copper industry to normal, a considerable field may be opened for the application of shale-oils to ore flotation.

Many other proposed byproducts have come in for attention, all of which present problems before anything commercially profitable can be developed from them. In the present state of the art, these can be listed only as suggestive of possibilities, for information is not available nor has the writer the specialized experience to catalog the problems which would be met in attempting their commercial application. Sheep dips, shale soaps[45] and insecticides[46] may be mentioned.

In almost all departments of the shale industry, many problems remain to be met, and in many cases the present knowledge is so fragmentary and proposed applications of this knowledge are so embryonic that one cannot even state intelligently the problems to be met. But that they will and must be solved cannot be doubted.

Potential Demand for Cosmetics in China

A potential demand for cheap grades of cosmetics in increasing quantities exists in China, says Consul General Cunningham in a report to the Department of Commerce. Native preparations are gradually giving way to imported articles. Highly perfumed toilet waters, face cream, powder and tooth paste are in demand.

[39] In this connection see Brownlee, U. S. Pat. 1,309,432.

[41] *Cf.* Botkin, C. W., Chem. & Met. Eng., vol. 26, p. 398, March 1, 1922; p. 445, March 8, 1922.

[42] For a review of the literature on coumarone resins from coal tars and their uses see *J. Ind. Eng. Chem.*, vol. 8 (1916), p. 797.

[43] For general information on ichthyol see "Tariff Information Surveys," A-12, Par. 561, Washington, 1921. It should be noted in this connection that the Meadows Chemical Corporation, 52 Vanderbilt Ave., New York City, has placed on the market an ammonium ichthyolate obtained from an asphaltic limestone found near Burnet, Tex. United States Pat. 1,271,387 and 1,073,548, owned by the Atlantic Refining Co., cover the preparation of a similar ichthyol substitute from filtered lubricating distillates from petroleum.

[44] Reference is had to the Muscle Shoals Oil Refineries (Ginet process), of Denver, Col., and "Mutual 100 Flotation Oil."

[45] The Oil Shale Mining Co., of Hastings, Neb., has put on the market soaps which are said to contain shale-oils.

[46] On the use of petroleum oils as insecticides see *J. Econ. Entom.*, vol. 11 (1918), pp. 70 and 299. It would seem that shale-oils, by reason of their unsaturated hydrocarbons and their content of alkaloidal compounds, might be expected to compare favorably with insecticides from petroleum.

"Science as Applied to Industry" at Yale*

By William E. Ford
Professor of Mineralogy in the Sheffield Scientific School, Yale University

A NEW course of study known as "Science Applied to Industry" has this year been offered to the students in the Sheffield Scientific School for the first time. Since this new course has proved to be the most popular choice of the present Sophomore class in the Scientific School, it having been elected by almost one-quarter of the entire class, it should be of interest to examine somewhat in detail its contents and aim.

In the past, many graduates of the Sheffield Scientific School who had taken technical courses, such as those offered in the various fields of engineering or in chemistry, have become after graduation managers and executives in various lines of industry rather than the technical men for whom their undergraduate course was designed. These men desired in their college course a thorough knowledge of the scientific fundamentals of their work and a mental training in scientific methods of thinking, but they did not need all the details of technical knowledge that a professional engineer or chemist requires. It was for this class of men—always numerous but increasingly so in the last decade—that the course known as Administrative Engineering was established last year, to be followed this year by the course in Science as Applied to Industry. To quote from the description of the latter course in the Scientific School pamphlet, "This course is not designed for those students who are seeking preparation for a professional career in some particular branch of science, such as chemistry or metallurgy, where problems of production are likely to occupy his attention; such professional training can best be secured in other courses. The prospective professional chemist, to mention a single instance, requires a training different from the prospective business manager in a chemical-manufacturing plant. It is to supply the training necessary for men to function intelligently and efficiently in important executive and managerial positions in the business world, where a knowledge of science and of the scientific approach to business problems is indispensable, that this course has been provided."

Plan of the Curriculum

In planning the curriculum of the course, naturally the first requirement was that it should include the elementary but indispensable courses in physics, chemistry and mathematics. Next, it was felt that no attempt should be made to cover the whole field of natural and physical science, but rather attention should be concentrated upon three branches of science—viz., chemistry, metallurgy and geology. The work in these sciences is so arranged that a natural and logical order of development is followed, covering, in some cases, 4 years of work in a single subject. A graduate of this course will therefore have acquired quite a comprehensive knowledge of these three scientific fields.

A business manager should be familiar with the characters and occurrences of the raw materials with which his business deals. The courses in mineralogy and geology cover this field for the mineral products while the course in zoology and botany which is offered as an option in Junior year will serve in a similar way for the animal and vegetable products. Secondly, he should be familiar with the methods by which these raw materials are prepared for industrial use. The courses in chemistry and metallurgy will, at least in part, meet this requirement.

In addition to these scientific subjects, the course includes in Junior and Senior years a series of courses grouped under the general heads of Social Sciences and Business Administration. These latter courses are naturally of great interest to the prospective executive.

The various courses offered are:

Sophomore Year. The total number of hours per week, including the hours allowed for preparation, is 48. The number of hours assigned to each subject is indicated in parentheses after the name of the course.

Mathematics (9). Physics (12). Modern Language (9). English Composition (4). Qualitative Analysis (8). Mineralogy (6).

Junior Year. The total number of hours per week for Junior year is 45.5. Of these, 34.5 are required, and one of the two options offered will provide the remaining 9 hours.

Physical Chemistry (6). Physical and Historical Geology (6). Elementary Metallurgy (9). Drawing (3). Industrial Mineralogy (3). Economics and Business Finance (7.5). The two options are Elementary Botany and Biology (9). Modern Language (9).

Senior Year. In Senior year the total hours must number 45, of which 37.5 are required, while the balance is to be made up of choice from a group of elective courses.

General and Physical Chemistry (9). Economic Geology, Elementary Petrology and Applied Structural Geology (9). Industrial Management (6). Statistics and Reports (3.75). Metals and Alloys (3.75). Principles of Accounting and Cost Analysis (6). The electives include Elementary Organic Chemistry (9), Industrial Chemistry (8), Economic and Regional Geology (6), Business Law (3.75). Insurance (3.75). Metallurgy of Iron and Steel (1.5). Transportation (3.75). Economic Problems (3.75).

The recent reorganization of the university led the Corporation to constitute the Sheffield Scientific School the undergraduate school for "professional study in Science and Engineering," while Yale College is to be the school for "non-professional study in the Liberal Arts and Sciences." It was further provided that the courses of study offered in the Scientific School should have "the major portion of their total work in approved courses in the Physical, Mathematical and Natural Sciences," while for students in Yale College "the 'Humanities' should normally constitute the major portion of their total work." The course Science as Applied to Industry is the least technical of the courses now offered by the Scientific School, yet its subjects of study fall well within the established limits. The total number of hours required during the three years in the Scientific School is approximately 137, of which the minimum number of hours that must be devoted to the physical, mathematical and natural sciences would be 84, or over 61 per cent of the total. By varying the character of the electives chosen, this percentage could be considerably increased.

This course is naturally only in its initial stages, and will doubtless undergo numerous minor modifications which time and experience may show to be desirable. It seems to the writer, however, that the fundamental ideas of the course are thoroughly sound and that it should give to an increasingly large group of men information of value to them in their business lives, and, what is of greater importance, a training in accuracy of thought and precision of judgment that is most essential to success.

*Reprinted from the *Yale Alumni Weekly* of Dec. 16, 1921.

Contributions to the Study of Ammonia Catalysts—II

Description of Apparatus Developed by the Fixed Nitrogen Research Laboratory and Used in the Small-Scale Testing of Ammonia Catalysts at Variable Pressures*

By A. T. LARSON and A. P. BROOKS

IN ANY comprehensive study of ammonia catalysts it is essential to have available a relatively small simple apparatus capable of operating under variable pressures of at least 30 atmospheres and preferably up to 100 atmospheres. Such an apparatus should possess mechanical simplicity, ease of construction, alternation and repair and flexibility of control, and yet be capable of sufficient precision to assure results of reasonable accuracy.

An apparatus of this type affords a much more rigorous test of catalysts than is afforded by the still simpler tests at atmospheric pressure. It is admirably adapted to the study of the effect of pressure, temperature, space velocity and poisoning by water or carbon monoxide.

It is not so suitable for such studies as deterioration of catalysts over long periods of time as is a larger and more elaborate testing plant. Furthermore, it bears little relation to a commercial unit and is therefore unsuited for a study of such factors at temperature gradient within the catalyst, or heat recovery.

In August, 1918, the Geophysical Laboratory, working under a grant from the Nitrate Division, Ordnance Department, U. S. Army, began a study of the ammonia synthesis problem, and an apparatus of the type described above was designed by Adams, Franklin and Meldrum. At the end of a year this work was abandoned by the Geophysical Laboratory and the apparatus was transferred to the Fixed Nitrogen Research Laboratory. The apparatus described in the present article is a development of that set up by the Geophysical Laboratory, in which many of the original features have been retained and others modified or abandoned as experience has indicated.

In the main this report considers only the apparatus as at present employed, including, however, certain features not now in use, but which may perhaps be useful to others. It is not intended to be an exhaustive study of the entire problem and will therefore not consider other possible methods of achieving the same results.

Outline of Complete Apparatus

In order to clarify subsequent detailed discussion of individual items it seems desirable to outline at this point the apparatus as a whole, referring to Fig. 1 for illustration.

The crude nitrogen: hydrogen mixture issuing from the high-pressure line passes through appropriate valves into the purification system. Four cylinders of the gas mixture are floated in the line to balance pressure changes. The purification system consists of a bomb containing colloidal Al_2O_3 for preliminary removal of moisture, oil or other readily condensible vapors; a bomb containing metallic copper at 400 deg. C. to serve as deoxidizer; a bomb containing a nickel catalyst at 275 deg. C. to hydrogenate carbon monoxide and other compounds; a series of three bombs containing Al_2O_3 to effect final removal of water vapor and other condensible gases.

From the purifying system the gas passes either directly to the catalyst bomb or to the humidifiers, according as dry or moist gas is to be tested. The humidifiers are essentially two small bombs containing water, the first at room temperature and the second maintained at a temperature designed to give the desired vapor pressure of water to the gas. Following the humidifiers is a trap, from which the gas passes directly to the catalyst bomb. From the catalyst bomb the gas passes through a valve, from which it issues at atmospheric pressure to the flowmeter and to the outlet tube from which samples for analysis are taken.

Copper tubing $\frac{1}{16}$ in. internal and $\frac{1}{8}$ in. external diameter is used to carry the gases. This tubing is connected through the walls of bombs and into valves, unions and tees by a standard device developed from the geophysical cone and gland and shown in Fig. 5. This consists of a steel tube $\frac{1}{8}$ in. in external diameter, terminating in a cone of $\frac{1}{4}$ in. diameter and a 59 deg. angle. Over the tube is fitted a steel gland, $\frac{5}{16}$ in. diameter, with $\frac{1}{24}$-in. pitch to its thread and a $\frac{1}{2}$-in. hexagon nut. By means of a steel sleeve the copper tubing is silver-soldered to the steel tube. This "cone and gland" is fitted into the shell of a bomb, or into a valve by cutting a standard gland and cone seat having a 60 deg. angle. By this device the bearing surface is reduced to a single line at the extreme inner edge of the cone tip. The torque required on the bushing nut to tighten the joint is very small and may be obtained by the use of a very small wrench or by hand. This type of connection is so frequently used and referred to that the above detailed description has seemed desirable.

Sources of Crude Nitrogen:Hydrogen Mixtures for Testing

Commercial cylinders of nitrogen and hydrogen under high pressures, provided with appropriate reducing valves and pressure flowmeters, may serve as the source of crude gas. The impurities in such gas, always considerable, and the attention needed for control of flowmeters render this method the least desirable.

A mixture of nitrogen and hydrogen gases in the ratio of 1 : 3 by volume may be obtained by decomposing ("cracking") ammonia, and if this is accomplished under pressure a self-contained apparatus becomes possible in which compressors are unnecessary. Such an apparatus, employing liquid ammonia as a source of both pressure and ammonia, has been developed by the Fixed Nitrogen Research Laboratory after designs originated

Copyright, 1922, by the Fixed Nitrogen Research Laboratory.

*For Part I see CHEM. & MET. ENG., vol. 26, No. 11, p. 493, March 15, 1922.

by the Geophysical Laboratory and has operated successfully for pressures not above 30 atmospheres.

The method finally selected for obtaining nitrogen: hydrogen mixtures consists in using gas "cracked" at atmospheric pressure and compressed to about 1,500 lb. by the large-scale testing plant of the laboratory. The "cracker" used will be described in the third article of this series. This method allows wide pressure range and extreme simplicity of handling and is to be recommended whenever compression facilities are available.

Reduction of pressure from the high-pressure line to the pressure selected for operation was at first achieved by periodically charging a series of cylinders arranged in parallel, of such capacity that considerable amounts of gas might be drawn from them without substantial change in pressure.

Later this method was replaced by the use of commercial gas-reducing valves of sufficient capacity and range to deliver gas at the desired pressure in quantity sufficient for the operation of several bombs at once. The valve used for 30-atmosphere testing is a modified Cash standard reducing valve.

Preliminary Purification

The importance of delivering to the catalyst bomb only gas of the highest possible purity or containing known amounts of definite impurities, as may be desired, can scarcely be overestimated. As mentioned in the preceding article, it is essential in a purifying system not only that it shall remove impurities present in the gas but also that it shall not introduce any impurities. The purification system herein described and indeed the apparatus as a whole is designed to achieve both of these results.

The gas received from the large-scale testing plant has already been subjected to purification, having been scrubbed with water, deoxidized and dried with alkaline driers. It is therefore free from ammonia and acidic constituents. It may, however, contain small amounts of carbon monoxide and in process of transfer to and from the storage cylinders it may acquire small amounts of moisture, oxygen and oil, from which it is almost impossible to free the steel cylinders. Preliminary purification of the gas is achieved by the use of a bomb containing granules of colloidal Al_2O_3. This serves to remove moisture, oil and other readily condensible vapors. The bomb is identical in construction and contents with those described later for the final drying. After this preliminary treatment the gas passes to the deoxidizer.

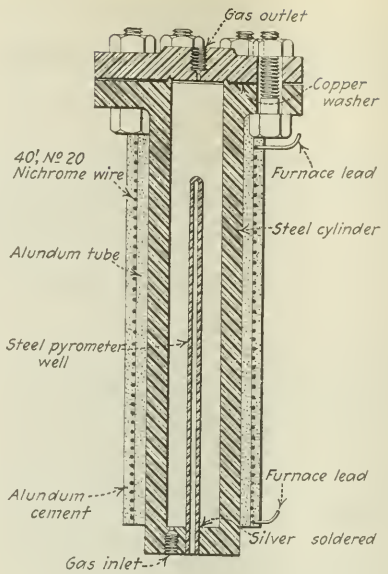

FIG. 2—DETAIL OF BOMB USED FOR COPPER DEOXIDIZER AND NICKEL CATALYST

Removal of Oxygen

Oxygen is removed by passing the gas over metallic copper heated to 400 deg. C. The final design of bomb for this purpose is shown in Fig. 2. It consists of a steel cylinder, 10 in. long, 2 in. external and 1⅛ in. internal diameter, closed at one end and widened at the other into a flange 4⅜ in. in diameter and ⅝ in. thick. A

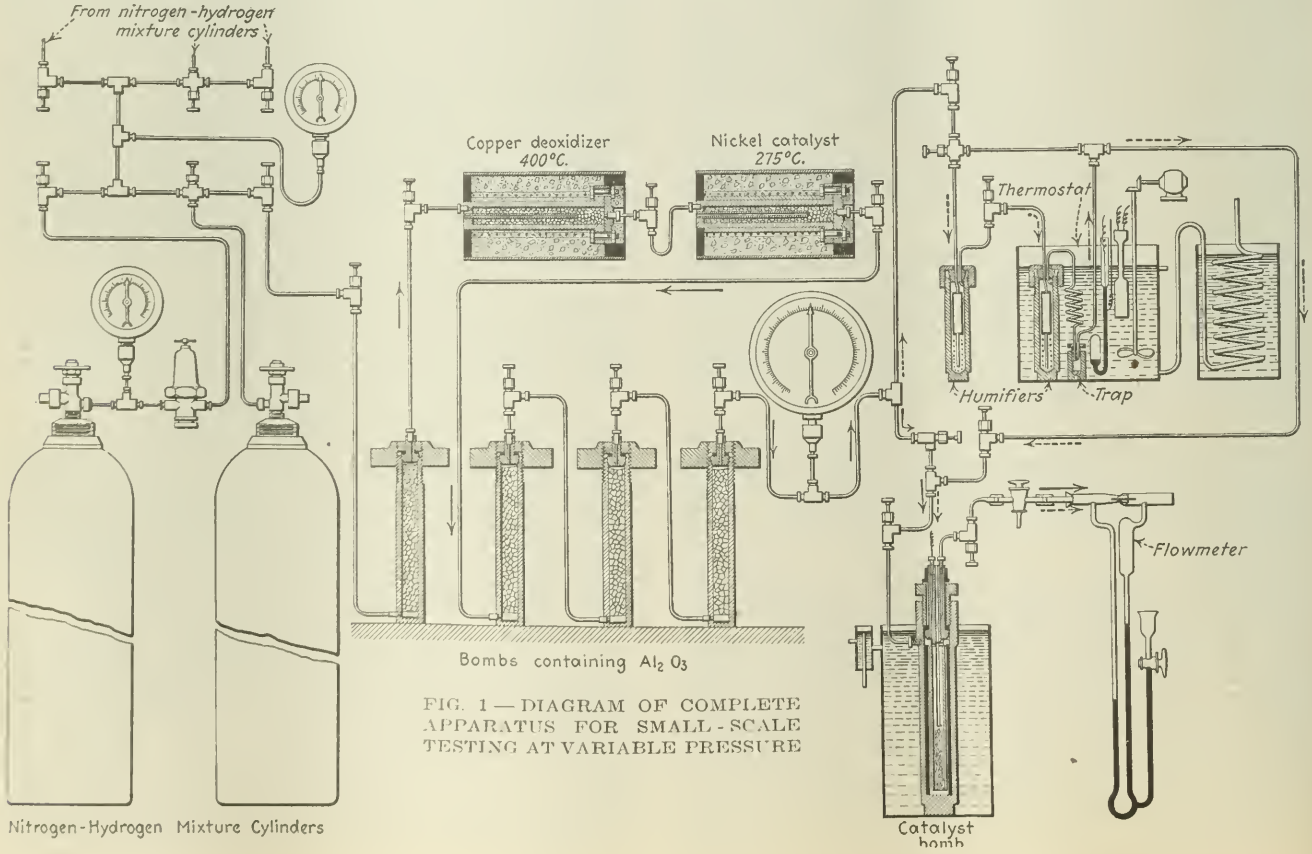

FIG. 1—DIAGRAM OF COMPLETE APPARATUS FOR SMALL-SCALE TESTING AT VARIABLE PRESSURE

head of the same diameter is fastened to the flange by seven ½-in. steel bolts. A copper washer fitting into an annular groove serves to make a gas-tight connection. The head is pierced in the center by a standard gland and cone seat as described above to serve as gas outlet. The other end of the bomb is pierced by a ¼-in. hole into which is silver-soldered a heavy wall steel pyrometer well 8½ in. long for temperature measurement. At one side of the pyrometer well a standard gland and cone seat is placed to serve as gas inlet. Over the steel bomb there is slipped an alundum tube wound with nichrome wire and packed with alundum cement, the whole fitting into a sheet-iron container. This bomb is charged with copper oxide, which is then reduced by the nitrogen: hydrogen mixture at as low a temperature as possible and is then ready for use as a deoxidizer.

Hydrogenation of Carbon Monoxide and Other Substances

It has been shown by Greenwood and Cowper[1] that small amounts of carbon monoxide are completely removed from hydrogen even at high space velocities by passing the mixture through a properly prepared nickel catalyst at 250 to 300 deg. C. The carbon monoxide is converted into methane, which is entirely inert toward ammonia catalysts. Other unsaturated bodies may be also hydrogenated and thus rendered more inert. In addition, the nickel may effect a marked rise in the boiling point of certain substances, thus rendering them more readily absorbable by Al_2O_3. This point is discussed later.

The catalyst used in the present purifier follows Greenwood's specifications. It is prepared by impregnating nonpareil brick, crushed and screened to 4 to 8 mesh, with sufficient nickel nitrate solution so that on subsequent ignition and reduction the product contains 10 per cent reduced nickel. The material is dried at 150 deg. C., placed in a bomb identical with that described for the copper deoxidizer and reduced at as low a temperature as possible in a current of nitrogen: hydrogen gas. the temperature of operation is 280 deg. C. ± 10 deg.

Removal of Moisture and Other Condensible Vapors

Three bombs containing granular colloidal Al_2O_3 (Fig. 1) similar to that used for preliminary purification serve for the final removal of any readily condensible gases, particularly moisture. The method of preparation of colloidal Al_2O_3 was described in the previous article and will not be discussed here. It should be noted, however, that subsequent drying with P_2O_5 produces no change in the behavior of the catalyst, nor does scrubbing with liquid Na-K alloy, which was used in early experiments.

The bombs used to contain the Al_2O_3 were not specially designed for the purpose and therefore do not represent any features of particular interest. They have, however, been quite satisfactory. They consist of a steel shell, 12 in. long by 2 in. external and 1¼ in. internal diameter, fitted at the top with external standard pipe threads, 11½ threads to the inch. The shell is drilled out at the top to 1$\frac{7}{16}$ in. diameter, ½ in. deep to form a seat for the lower face of the head. A steel head with a conical base fits into this seat, a soft copper gasket serving to make gas-tight connection between the two. The head is kept in place by a large steel nut, fitting over the head and screwing over the end of the shell, a washer of Monel metal being placed between the head and the nut. The steel head is pierced by a standard gland and cone seat to serve as gas outlet and the bottom of the shell is pierced by a similar gland and cone seat to serve as gas inlet.

After passing through three of these Al_2O_3 bombs the gas is free from detectable moisture and is ready to enter the catalyst bombs for experiments on pure dry gas.

The effectiveness of the purifying train may be illustrated by a series of experiments carried out upon the gas at different stages of its purification. A coil of glass tubing was prepared through which the gas at any point in the line could be passed after reduction to atmospheric pressure by a valve. This coil was immersed in liquid air contained in a vacuum flask. On testing in this way the crude gas issuing directly from the high-pressure line at the rate of 500 c.c. per minute, an immediate cloudiness appeared in the upper part of the coil much above the liquid air, indicating the presence of considerable quantities of high-boiling liquid, probably largely water. There also appeared in a colder part of the coil just above the liquid air a condensate of very low-boiling material which evaporated very readily when the coil was removed from the liquid air, giving an odor characteristic of organic substances. On testing similarly the gas after passing the nickel catalyst, the low-boiling material had disappeared, leaving only a condensate of high-boiling material. Assuming that the low-boiling material consisted of hydrocarbons or their derivatives, the effect of the nickel catalyst had evidently been to convert them to substances having a boiling point of the order of that of water. On testing the gas after passing the aluminum oxide towers, no trace of condensate of any kind appeared for half an hour, when a faint cloudiness due to high-boiling material appeared. It is thus evident that a very complete removal of water or any other substance condensible by liquid air has been effected by the purifying system.

Introduction of Moisture and Other Poisons When Desired

Since in any commercial plant it is almost certain that the gas used will contain small amounts of certain impurities, it is essential to be able to study the effect upon the behavior of the catalyst when definite amounts of impurities are introduced into the gas stream. The two chief impurities which will probably always be present in commercial gas are water vapor and (when water-gas hydrogen is used) carbon monoxide.

Water vapor is introduced into the system when desired by passing the gas issuing from the purification system through two humidifiers.

These consist essentially of small bombs of brass containing water through which the gas is bubbled. Brass is used instead of steel in order to avoid rusting and also because of ease of construction and rapidity of heat interchange. Their construction is shown in Fig. 3. They consist of a brass shell, 7¼ in. long by 1¾ in. external and ⅞ in. internal diameter, fitted at the top with 1 in. of external pipe threads, 14 threads to the inch, to which the head is screwed. The head consists of two parts, a plug of Monel metal, as illustrated, pierced by two holes into which the inlet and outlet tubes, of ⅛ in. copper tubing, are soldered. Over this plug the head, a hexagonal nut of brass, 2⅜ in. diam-

[1]Munitions Invention Department, Ammonia Synthesis, No. 12.

eter and 1½ in. thick, is fitted, screwing over the top of the shell. The inlet tube terminates in a brass safety trap, designed to prevent water from accidentally sucking back into the system.

Following the second humidifier is a small brass trap of simple design (Fig. 3). It consists of a shell of brass 2 in. long by 1¼ in. external and ½ in. internal diameter, fitted at the top with internal screw threads to hold the head, and at the bottom pierced by a hole into which is soldered a short drain of ⅛-in. copper tubing. This drain is closed by a soft solder plug to permit

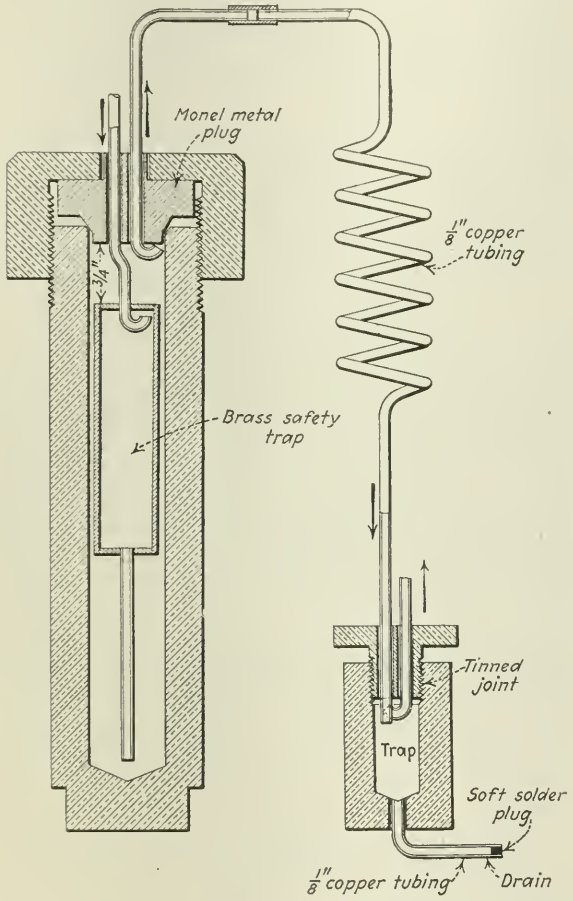

FIG. 3—HUMIDIFIER AND TRAP

drainage when desired. The head is a simple brass nut, pierced by two holes through which the inlet and outlet tubes of ⅛-in. copper tubing are soldered.

In practice, two of these humidifiers are used in series, the first one operating at room temperature and the other (with the trap) at a temperature controlled accurately by a thermostat at such a point as to give the desired degree of humidification. In this way saturation of the gas with water vapor at the desired temperature is achieved from the supersaturation side rather than the unsaturation side, a method which is shown to give more uniform results.

The gas issuing from the purification system passes through a tee valve, either directly to a manifold line leading to the catalyst bombs or through the humidifiers to a separate manifold. It is thus possible to operate one catalyst on dry gas while another is being operated on moist gas and at the same time to avoid contaminating the entire system with water vapor.

Carbon monoxide is usually introduced into the gas when desired at the large-scale testing plant where it is mixed with the nitrogen and hydrogen prior to compression. It may also be introduced into the storage cylinders at low pressure before filling them with the nitrogen: hydrogen mixture from the high-pressure line. When testing gas poisoned with carbon monoxide the nickel catalyst is, of course, not operated.

Description of the Catalyst Bomb

The catalyst bomb is the most elaborate single unit of the complete apparatus and one which represents some of the greatest difficulties of construction. Its design is essentially based upon that of the bomb developed at the Geophysical Laboratory by L. H. Adams. A detailed sketch of the modified bomb is shown in Fig. 4 and should be used in following the description.

The shell is of steel, 15¼ in. long by 2⅝ in. external and 1 1/16 in. internal diameter, enlarged at the head to 2 5/16 in. external and 2⅛ in. internal diameter, and fitted at the head with internal screw threads, nine threads to the inch. Just below the screw threads several seats

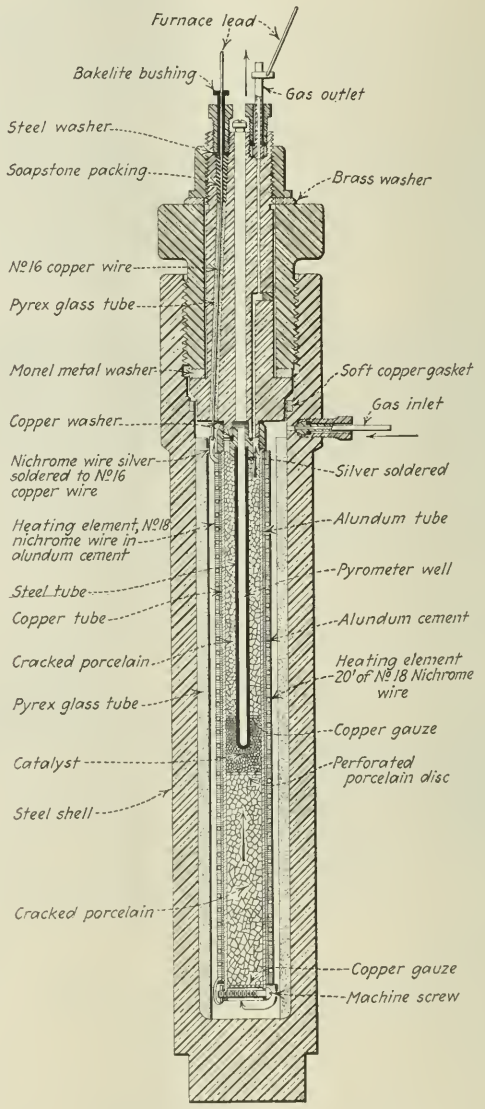

FIG. 4—CROSS-SECTION OF CATALYST BOMB

are provided, as illustrated, to fit the head and various washers, and just below these seats the side is tapped by a standard gland and cone seat to serve as gas inlet.

The head, itself of two distinct units, contains the pyrometer well, the gas outlet (a standard gland and cone seat) and the lead wire for the internal heating

element. The two parts of the head are fitted to each other by an upper washer of brass and a lower one of Monel metal. Gas-tight connection between the shell and the head is effected by the use of a gasket of soft annealed copper. It should be noted that only at this gasket is there a connection between head and shell which is subject to the stream of high-pressure gas.

One of the heating leads is connected directly to the head; the other is insulated from the head by passing through a Bakelite bushing into a conical soapstone plug, held in place by a steel washer. This type of high-pressure insulation has proved quite satisfactory. A Pyrex tube protects the lead wire from contact with the head after passing the soapstone plug, until it reaches the heating element to which it is silver-soldered.

The copper catalyst tube, 10½ in. long by ¾ in. external and 0.642 in. internal diameter, is open at both ends and is silver-soldered to a steel sleeve which screws into the lower end of the head.

Surrounding the copper tube is a thin alundum tube on which is wound the heating element, 20 ft. of No. 18 nichrome wire, imbedded in alundum cement. The winding is so designed as to give as little temperature gradient as possible within that portion of the tube containing the catalyst. A Pyrex tube, fitting closely the interior of the steel shell, serves to protect the steel from the hot gases and lessen the heat transfer to the walls of the shell.

Operation of Catalyst Bomb

The operation of the bomb will be briefly described. The catalyst tube is filled by unscrewing the head with catalyst tube attached, reversing it and filling the tube half full of broken porcelain. Upon this is placed a copper gauze and upon this the layer of catalyst, about 1 in. in depth, so adjusted that the end of the pyrometer well is near its center. A perforated porcelain disk covers the catalyst and the tube is then completely filled with more broken porcelain, kept in place finally with a copper gauze, which in turn is held in place by a bolt to which the lower end of the heating element is attached. After being filled the head is then turned right side up and screwed into the shell.

The gas entering through the side of the shell above the catalyst tube passes down between the heating element and the outer Pyrex tube, thus becoming preheated, then upward through the catalyst tube and through the outlet in the head.

This bomb may be operated at any pressure up to 100 atmospheres and is capable of rapid temperature variation when desired. In order to permit the rapid temperature change the bomb is immersed in hot water, which, although causing a larger current consumption, permits greater rapidity of reaching temperature equilibrium than would be the case if the bomb were packed in heat-insulating material. The water also serves to diminish the temperature of the head, thus avoiding damage to the insulating device and sticking of the screw threads.

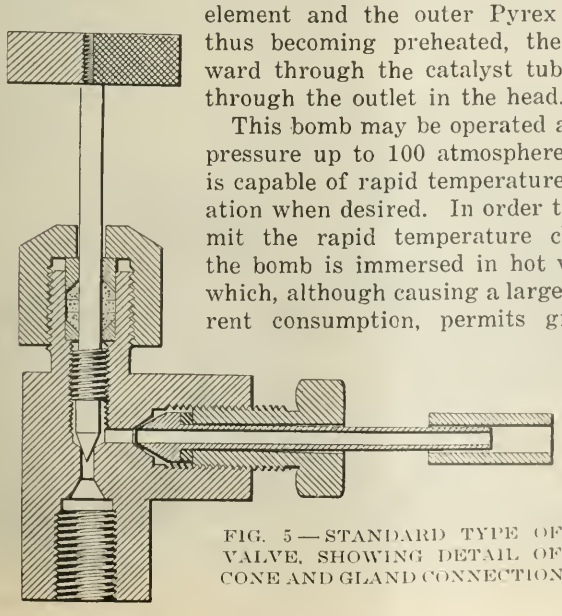

FIG. 5—STANDARD TYPE OF VALVE, SHOWING DETAIL OF CONE AND GLAND CONNECTION

It should be noted that when first constructed such a bomb (as the case of all other steel apparatus) is apt to contain considerable amounts of oil, soaked into the steel. This can best be removed by heating the bomb at about 600 deg. C. for several days in a current of pure gas until there is no longer evidence that oil is being carried through.

Control and Measurement of Gas Flow

The gas issuing from the high-pressure line passes through a commercial diaphragm reducing valve to a series of cylinders simply serving to balance the system against sudden changes of pressure. From this time on its control is achieved by the use of a number of small steel valves, whose design in shown in Fig. 5. These valves are connected into the pipe line, by means of the standard gland and cone seat, between all items of the system, and also serve for bypasses where desired. One of them releases the pressure after the gas passes the catalyst bomb.

Fig. 5 is almost self-explanatory, but it should be pointed out that the cone of the stem has a 30 deg. angle; that the stem packing of asbestos, previously slightly lubricated with paraffine and placed between cupped steel washers, has proved satisfactory; and that it is an advantage to make the diameter of the stem equal to that of the root of the screw thread—namely, ⅛ inch.

The measurement of gas flow is effected after reduction of pressure by a glass flowmeter of standard type, xylene being used as measuring liquid in the arms. These meters[2] are calibrated by stopwatch and water displacement.

Control and Measurement of Pressure

Pressure in the system is controlled by the reducing valve previously mentioned. It may be noted that in a self-contained apparatus utilizing liquid NH_3 as a source of both gas and pressure, the pressure is determined by the temperature at which the ammonia cylinder is kept.

Pressure is measured on 8½-in. American standard hydraulic gages, graduated in 5-lb. divisions. All gages are of the usual Bourdon copper tube type. They are carefully calibrated from time to time against a hydraulic apparatus, using known weights as pressure standards.

Control and Measurement of Temperature

Temperature control is needed (1) in the copper deoxidizer, (2) in the nickel catalyst, (3) in the second humidifier and (4) in the catalyst bomb.

With the exception of the humidifier, which is immersed in a water thermostat of appropriate size, the heating is effected in all of these cases by the use of nichrome heating elements, operating on the 110-volt circuit in series with rheostats. The rheostats are made in very fine steps, permitting continuous variation of temperature over a considerable range. No automatic control of temperature is attempted.

Temperature measurement is effected by chromel-

[2] *J. Ind. Eng. Chem.*, vol. 11, p. 623 (1919).

alumel thermocouples leading into the pyrometer wells, the cold junction being maintained in a vacuum flask filled with crushed ice.

The temperatures are read by means of a White double potentiometer, manufactured by Leeds & Northrup and permitting the estimation of temperature to within ½ deg. C. over the entire range of 200 to 700 deg. C.

It is most important in a critical study of ammonia catalysts that the temperature of the catalyst mass should be as uniform as possible and that the recorded temperatures should correspond exactly to those existing in the catalyst. The method of winding the heating element and the high thermal conductivity of the copper catalyst tube and steel pyrometer well contribute to achieving the former result; the latter is effected by careful calibration of all thermocouples every 2 weeks, against boiling sulphur. It is believed that the recorded temperatures do not vary from those actually existing in the catalyst mass by more than 2 to 3 deg. C.

Analytical Control

Since the effectiveness of the catalyst is measured by the ratio of ammonia to nitrogen: hydrogen in the outlet gases, this represents the only necessary analytical determination. The method of analysis finally adopted is to pass the gas issuing from the catalyst bomb, after being reduced to atmospheric pressure, through a 4 per cent solution of boric acid, to absorb ammonia, and then into a compensometer[3] by means of which the volume of the nitrogen: hydrogen mixture can be rapidly and conveniently measured. The boric acid solution is then titrated directly with standard H_2SO_4, using methyl orange as indicator, and titrating to a definite color standard as end point. Experiments show that absorption of ammonia from the gas stream by boric acid is extremely rapid and complete and the method permits the use of only a single standard solution.

Conclusion

The apparatus herein described has been used for testing ammonia catalysts under varying conditions of pressure, temperature, space velocity and purity of gas. The results of these investigations will be discussed in the fourth article of this series.

(*The third article of this series, describing a moderate-scale apparatus for testing ammonia catalysts at* 100 *atmospheres pressure, will appear in a subsequent issue.*)

Coal Available in Case of Strike

An analysis of the coal situation, the purpose of which is to give business men information regarding possible fuel supplies in the event of a strike of miners on April 1, has been issued by the Coal Bureau of the Natural Resources Department of the Chamber of Commerce of the United States. The bulletin carries charts covering conditions in particular localities.

As the anthracite field is 100 per cent unionized, all supplies in the event of a complete closing of the mines will have to be drawn from stocks on hand. Reliable figures on which to base an estimate covering possible anthracite supplies in the event of a strike completely closing the mines are not available.

Assuming this year's bituminous consumption to be comparable to that of 1921, 7,600,000 tons per week, the supply from non-union fields would fall short 3,600,000 tons per week of meeting the demand.

[3] See Chem. & Met. Eng., vol. 23, No. 23, Dec. 8, 1920, p. 1104.

A Paddlewheel Fan Adapted for the Removal of Suspended Particles

A modification in the design of the ordinary paddlewheel type of fan blower, whereby it is adapted for the removal of cinders and dust from the air it handles, has been developed by the B. F. Sturtevant Co. Buckets are provided at the inlet edges of the blades as shown in Fig. 1. From each bucket an inclined channel leads the dust to a special dust chamber, where it drops out of suspension and is removed from hoppers periodically.

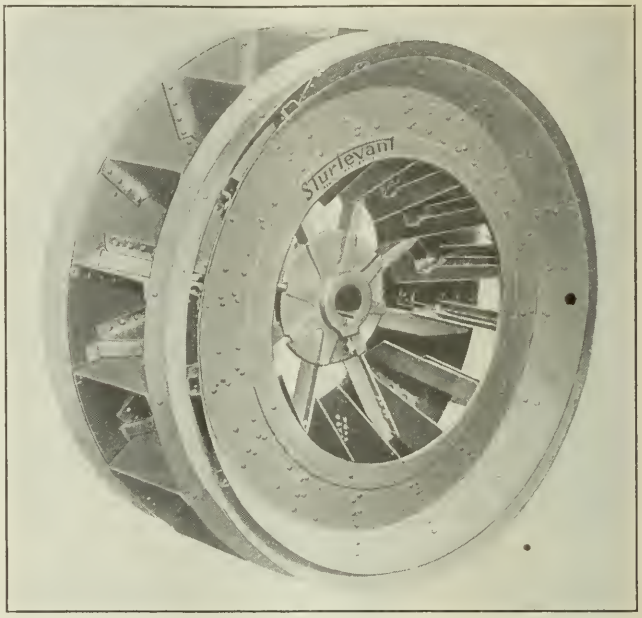

FIG. 1—ROTOR OF FAN, SHOWING COLLECTING BUCKETS AND CHANNELS

It is claimed that this type of blower is just as efficient as a fan as the average induced draft fan and that it removes up to 75 per cent of the solid matter in the air, depending, of course, on the nature of the material. Two large fans installed in connection with six 500-hp. boilers in New York City each remove about 250 lb. of cinders per hour when the boilers are operating at 200 per cent of rating. This type of fan has also found successful application in connection with boilers using pulverized fuel and should be useful in the chemical and metallurgical industries where the removal of suspended matter from gases is desirable.

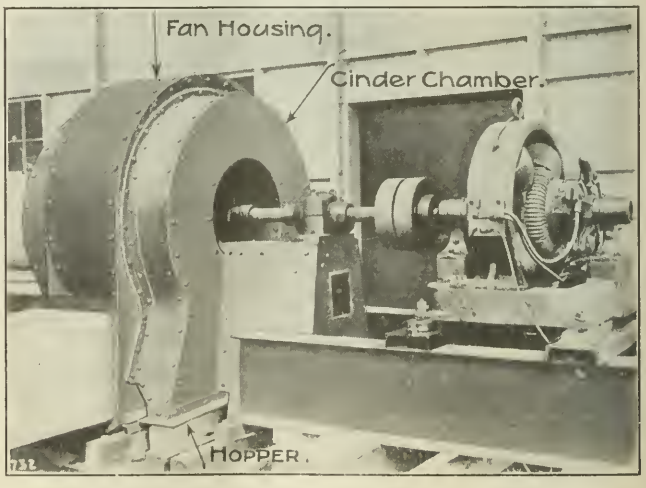

FIG. 2—ASSEMBLED FAN, SHOWING CINDER CHAMBER AND HOPPER

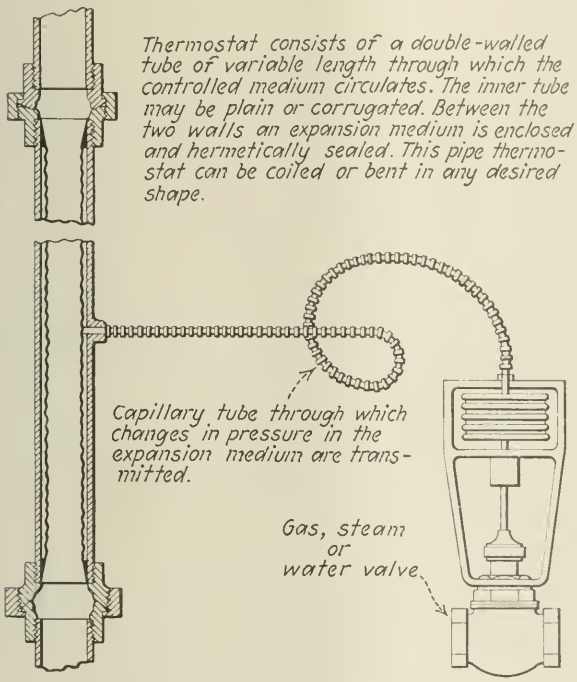
A New Temperature Regulator

Most of the temperature regulators on the market at the present time use tabular thermostats similar to the bulb of a distance thermometer. This tubular thermostat is commonly inserted in the heater, tank or receptacle the temperature of which is controlled. It frequently happens, however, that there is no room for the thermostat in this location and it is necessary to insert it in an outside pipe or a special chamber. This has certain obvious disadvantages. For instance, it involves extra expense in installation and the pipe or chamber tends to form a pocket, hindering the flow of the liquid, which in turn may result in irregularity of control.

A consideration of the problem involved and the existing methods has suggested the use of a pipe thermostat of the type shown in the accompanying illustration. This thermostat, which was recently developed



Thermostat consists of a double-walled tube of variable length through which the controlled medium circulates. The inner tube may be plain or corrugated. Between the two walls an expansion medium is enclosed and hermetically sealed. This pipe thermostat can be coiled or bent in any desired shape.
Capillary tube through which changes in pressure in the expansion medium are transmitted.
Gas, steam or water valve

and patented by H. J. C. Wells of the Sarco Co., Inc., consists of a two-wall pipe in which the expansion medium, whether a sensitive oil or a volatile fluid, such as ether, is located between the two walls. In this construction not only is the controlled liquid allowed a free passage but the sensitiveness of the regulator can be greatly increased. This latter point will be appreciated if one takes into account that an ordinary thermostat tube or bulb has a certain definite proportion of heat-interchanging surface for a given content of the expansion medium it contains. On the other hand, with a pipe thermostat it is feasible to extend the length of the pipe considerably and its two walls can be so close together as to take between them little more than a film of liquid or a layer of gas; thus the ratio of heat-interchanging surface and volume of expansion medium is increased almost indefinitely. This results in nearly instantaneous heat interchange and reaction. The lengthening of the pipe thermostat involves no particular constructional difficulties, as it can be coiled, bent or otherwise deformed and in fact may constitute a part of the regular conduit used to convey the medium controlled.

Many applications for such a thermostat suggest themselves. For instance, certain heaters for liquids can be equipped with a pipe thermostat simply by substituting it for the exit pipe. Another application is in connection with the temperature control of the cooling water systems of air compressors and of gas and oil engines. The pipe thermostat takes the place of the discharge pipe and occupies practically the same space as the pipe now used. With gas-fired boilers, the pipe thermostat would be placed in the return circulation pipe and directly control the gas supply. In pasteurizers for milk, cider and other fruit juices, which are heated while in circulation, the pipe thermostat is preferable, because of its greater sensitivity and the ease with which it can be cleaned. The construction of the thermostat in the form of an open pipe may have other advantages, where the temperature of corrosive gas or liquids is controlled, since the inner wall can be of some acid-resisting material and the use of internal joints and solder entirely avoided.

Without impairing the useful field of the tubular thermostat for ordinary tank control, the pipe thermostat appears to offer decided advantages in these special applications.

Synopsis of Recent Chemical & Metallurgical Literature

Developments in Refrigeration.—In a paper on this subject read before the Glasgow Section of the Society of Chemical Industry by Dr. W. R. Ormandy and E. C. Craven and printed in *Chemical Age*, of London, on Feb. 4, 1922, the authors pointed out the disadvantages of the ammonia absorption system of refrigeration using water as an absorbing medium and suggested the use of solid ammonium nitrate for absorbing the ammonia gas.

When ammonia gas is passed over cooled ammonium nitrate, a liquid is formed possessing at ordinary temperatures the composition $2NH_4NO_3NH_3$ and freezing at 22 deg. C. At lower temperatures a compound $NH_4NO_3NH_3$ appears to be formed.

It was found under certain conditions the ammonium nitrate was changed into a cellular state, in which the full vapor pressure of the liquid compound was not exerted. To overcome this difficulty the liquid compound was absorbed in kieselguhr in such proportions that a dry powder was formed, reducing this possibility to a minimum.

In application to practice the authors state that against back pressures up to 190 lb. per sq.in. absolute all the ammonia-ammonium nitrate bodies containing over 6 per cent of ammonia were decomposed at a temperature of 230 deg. F., and that it required so much heat to drive off the remainder of the ammonia gas as to be uneconomical. At 144 lb. per sq.in. absolute back pressure all the bodies over 6 per cent NH_3 were decomposed below the boiling point of water. A stationary plant without agitation would work with ammonium nitrate-kieselguhr in the ratio 3 to 2 by weight, provided the cooling arrangements in the generator for the absorption period were adequate. There was no difficulty during generation with the absorbent present.

Determination of Oxygen in Hydrogen.—Alfred T. Larson and Ernest C. White of the Fixed Nitrogen Laboratory at Washington have made a valable contribution to the operation of the Haber process by publishing a simple and rapid method for determining traces of oxygen in hydrogen. The paper appears in the January, 1922, number of the *Journal of the American Chemical Society* (vol. 44, No. 1, p. 20). One method has been to estimate the oxygen content by passing the gases over a contact mass which converts the

oxygen into water; the water being collected in an absorbent, usually phosphorus pentoxide, and then weighed. It is desirable to determine the presence of oxygen down to 0.001 per cent, and at this dilution it requires no less than 62 liters of the gas to produce 1 mg. of water. Because of the difficulties involved in the weighing of such small quantities of water, the method is both slow and inaccurate. Another method depends on the conversion of colorless cuprous solutions into blue cupric solutions by the presence of oxygen. The intensity of the color change becomes the measure of the oxygen content, but it lacks accuracy in low concentrations.

The new method is rapid and accurate for concentrations down to 0.001 per cent, and it is based in principle on the method of Lamb and Larson in determining low concentrations of carbon monoxide in air. In the new method, the trace of contained oxygen is catalyzed by platinum with the excess of hydrogen at a temperature of 275 to 300 deg. C. The temperature rise due to the exothermic reaction is measured by a copper-constantan thermocouple and a sensitive potentiometer. The apparatus must be calibrated by the use of gas mixtures of known concentrations, but this proves to be a very simple matter, the potentiometer deflection being plotted against the oxygen content, making possible results accurate to 0.00003 per cent of oxygen. Full details of construction and manipulation of the apparatus are given.

Brinell Hardness of Cementite.—The Brinell hardness of cementite is not known, according to Messrs. Portevin and Bernard in a paper entitled "Contributions to the Study of Coalescence in Steels and Its Commercial Results" before the Paris meeting of the British Iron and Steel Institute. It is not even possible to ascertain it directly by any of the usual methods on account of its extreme brittleness. The investigation, however, of the products of coalescence furnish the following methods of ascertaining it indirectly by extrapolation:

It is known that the hardness of binary alloys formed of a mixture of two similar constituents in variable proportions is practically a linear function of the composition when the structural elements remain constant in size. Furthermore, if the proportions of the constituents remain constant, the hardness will tend to increase as the fineness of the structural elements.

Iron-carbon alloys in the annealed state consist of two

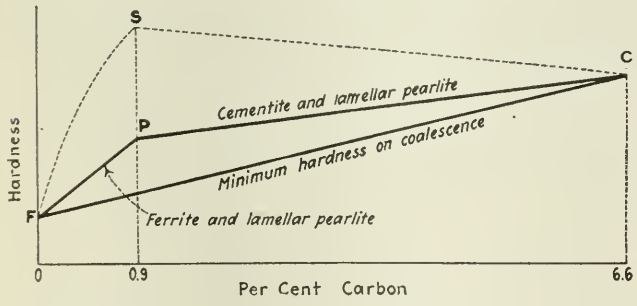


FIG. 1—BRINELL HARDNESS OF IRON-CARBON ALLOYS

phases, Fe_γ and Fe_3C, intermingled, but the structural elements of which these elements are composed vary considerably in size according as they do or do not form part of the eutectic pearlite in its lamellar form. This lamellar pearlite forms a definite aggregate with 0.9 per cent of carbon and a Brinell hardness in the neighborhood of 250.

According to the rule just enunciated the Brinell hardness of iron-carbon alloys, starting with pure iron and going up to 6.60 per cent of cementite in the annealed state, can be represented as in Fig. 1. Thus: For the products containing pearlite in the lamellar state, by two straight lines, *FP* and *PC*, connecting the points indicative of the hardness of pure iron (*F*), of lamellar pearlite (*P*), and of the cementite (*C*). For the coalesced products in such a manner as to connect all the cementite elements in globular form, and of the same order of size, by a straight line of minimum hardness, *FC*. And lastly, for the products containing the whole of their carbon in the sorbitic state by an ill-defined curve, *FSC*, relating to the maximum hardness in the annealed state.

It is practicable to plot points on the line *FC*, the minimum hardness of various steels and cast irons, a value which may be estimated by studying the degree of spheroidization of the cementite. Thus, whereas a piece of 1 per cent carbon-steel exhibiting lamellar pearlite, had a Brinell hardness of 262, after proper spheroidizing or coalescing, it dropped to 137. Accepting the hardness of ferrite as 75 (according to Howe) the Brinell hardness of cementite becomes about 400.

Recent Chemical & Metallurgical Patents

American Patents

Complete specifications of any United States patent may be obtained by remitting 10c. to the Commissioner of Patents, Washington, D. C.

Heating Practice.—Arthur E. Bellis, of Springfield, Mass., recommends that metal be heated in a salt bath prior to forging, rolling or other hot work. Accurate temperature control is possible, and when withdrawn the metal is covered with a thin film of salt which prevents surface oxidation and helps to avoid uneven chilling by variable air currents. In this manner scaling is reduced to a great extent and trouble and expense consequent to oxidation are avoided. (1,399,044. Dec. 6, 1921.)

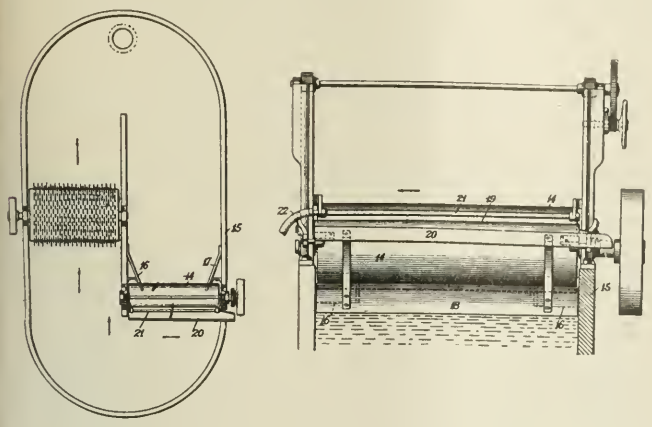
Method of Alloying.—Aladar Pacz, of Cleveland, Ohio, uses an intimate, very fine-grained mixture of alloying element and an oxide acidic to it to introduce the former into an alloy. For instance, he precipitates a mixture of tungstic acid and silicic acid, and reduces the mixture to tungsten impregnated with 2 per cent of silica. Twenty-one parts of this are melted with 150 parts of steel having the requisite amounts of carbon, chromium and other elements except tungsten required for high-speed steel, to produce tools having superior qualities. (1,402,088; assigned to General Electric Co. Jan. 3, 1922.)

De-inking of Paper.—In a recently patented method for removing printer's ink from paper, the waste paper (printed newspapers) is macerated in an ordinary beater or is shredded by other means and the stock then transferred to the beating engine. After heating to about 140 deg. F. and made up to a consistency of about 6 per cent, enough soda ash or other alkali is added to give the whole a decided alkalinity. After beating for a short time, say from 10 minutes to half an hour, sufficient ordinary laundry soap is added to form a saturated solution and the beating is continued until the oil of the ink is thoroughly emulsified.

At this stage sufficient cold water is added to bring the consistency down to about 3 per cent and to reduce the temperature to 100 deg. F. The effect of adding the cold water is not only to thin down the stock but also to throw more or less of the soap out of solution, with the result that as the agitation or beating continues, the emulsified soap, oil and pigment will rise to the top in the form of dark soapy bubbles. These may be removed from the surface of the stock as it flows around the beater by any convenient means, as for example by rotary washing screens but preferably by a rotary skimming mechanism devised by the patentees. This mechanism consists of a wooden roller 14 so arranged that its under side just touches or is but slightly above the surface of the stock. In front of the skimming roller are two inclined deflectors 16, 17, extending under the roller as indicated in the accompanying figure, for the purpose of concentrating the bubbles toward the center of the roller. Beyond the roller is a dam 18 extending transversely across the channel between the midfeather and the side wall, and preferably inclined, with its upper edge close to the roller 14. The dam extends down a short distance into the stock, so that its effect will be to cause the stock itself to flow down and under the dam, while the bubbles, trapped by the dam,

and brought into contact with the under side of the roller, may adhere to the latter and be carried upward.

Across the roller at a suitable point below the top thereof is a doctor 19 in close contact with the roller, so that the bubbles are scraped off by the doctor as the roller revolves. The doctor is inclined, as indicated, and at its lower edge is a backstrip 20 forming a trough. The trough thus provided



is slightly inclined so that the oil, pigment and other matters will tend to flow down the same and out over the side of the wall 15, where they can be discharged. To facilitate this flow of the material, a spray pipe 21 is provided, extending across the doctor at a slight distance about the same and connected at one end, as 22, with a source of water under pressure. The pipe has a series of perforations on its under side, so that the water is discharged in the form of jets upon the doctor to wash down the material scraped from the skimming roller.

After the stock has been cleansed by skimming and washing as described, it may be formed into standard pulp laps on an ordinary "wet machine," or it may have added to it in the beater such color and mordant as may be desirable, and may then be run directly to the paper machine. For some purposes it may be mixed with new pulp in any desired proportion. (1,406,222; Arthur F. Allen, and Alfred F. McCoy of New York City and Robert O. Sternberger of Newark, N. J., assignors to Tidewater Paper Mills Co., Brooklyn, N. Y., Feb. 14, 1922.)

Corrosion-Resisting Steel.—Aladar Pacz, of Cleveland Heights, Ohio, notes that the disadvantages of using ingot aluminum as a deoxidizer in steel making are removed if an aluminum-silicon alloy (10 to 40 per cent Al) is used instead. The reactions proceed more slowly and produce a fusible slag which separates easily. Furthermore, the alloy is brittle, so it may readily be pulverized and incorporated with the metal bath. If sufficient excess of the alloy is used so that from 1 to 18 per cent elemental Al (with a corresponding amount of Si) remains in the alloy, the resulting metal resists corrosion even at high temperatures. It also has a low magnetic hysteresis loss, and is therefore desirable for certain electrical apparatus. (1,396,276; Nov. 8, 1921.)

Contact Sulphuric Acid.—Specification covers the principle of drying the air supplied to the sulphur burner in order to prevent formation of acid mist in the burner and combustion chamber. It is said that this mist carries dust and other mechanical impurities and also impurities from the sulphur and from the action of sulphuric acid on the iron of the system. Molten sulphur is fed to the burner and the air necessary for its combustion is dried in two sulphuric acid scrubbing towers, followed by suitable spray catchers and filters to remove any acid spray carried over by the air. It is proposed that the air be dried in two stages, in the first using acid of moderate strength and of variable but controlled temperatures so that the air may have such predetermined humidity as may be required for the most efficient conversion reactions; in the second stage, using strong relatively cool acid in order to complete the drying to the extent required.
